The paper was an exhaustive review of the subject of adulteration of food as practised by the tradesmen of England and the United States in the past and at present. Great Britain was pronounced to be the historic field of food-adulteration, because it had been the most fervent centre of all industries, of all commerce, and of all modes of money-getting. From the long list of adulterations mentioned may be taken the following:

Wheaten flour, with rice, barley, peas, beans, buckwheat, millet, and boiled potatoes; bread with alum, sulphate of copper; yeast with alum; baking-powders with terra alba, such as plaster-of-Paris, whiting, and kaolin; milk with sugar, salt, soda, and chalk, annotto and turmeric, gum dextrine, emulsion of hemp-seed, boiled starch, and pulverized brains; cheese with potatoes, beans, vermilion red and red chalk, sulphate of copper, arsenic, and corrosive sublimate; lard with boiled starch, alum, and quicklime; confectionery with chromate of lead, red lead, and vermilion, Prussian blue, copper, and arsenic; pickles with sulphuric acid and verdigris; mustard with wheat flour and turmeric, charlock seed, cayenne, and ginger; coffee, ground, with roasted acorns, spent tan-bark, spent logwood, mahogany, sawdust, and burnt horses' liver.

Professor Johnson said: "Are we in the United States liable to suffer in purse and in health from the adulterations that are now practised upon our food? The reasonable answer is a qualified negative. We are not suffering serious loss of goods or of health." A communication was read from Leroy Parker, of the Michigan State Board of Health, recognizing the importance of the subject, and urging the necessity of arousing public opinion to secure the enforcement of laws against the adulteration of food.

After the reading of this paper, **MR. GEO. P. ANGELL** began a discussion, in which he claimed that adulterations were much more common and excessive than was indicated by Prof. Johnson. He finally read the following:

Whereas some chemists and writers have asserted that there is now a large sale, in American markets, of poisonous and dangerously adulterated foods and other poisonous and dangerously adulterated articles; and whereas other chemists and writers deny these assertions; and whereas the public health, public morals and large amounts of capital are interested in the right solution of this question; and whereas it is essential to its right solution that both sides be fairly heard; therefore, I make the following proposition to the American Social Science Association, viz.: I will put into the hands of its treasurer or general secretary either $50 or $100, whichever sum may be required, provided any chemist or other person in the United States will do the same, said sums to be expended as follows: such chemist or other person shall prepare or cause to be prepared an essay showing that there is little danger to public health from the above cause, and giving proofs. I will then prepare or cause to be prepared an essay of similar length showing that there is great danger to public health from said cause, and giving proofs. The two shall be published by the association in one pamphlet, and sent to all leading newspapers of the country for such use as they shall deem judicious.

(This proposition has, we learn, been accepted by Dr. H. A. Mott, of New York, on condition that Mr. Angell prepares his paper first and submits it to Dr. Mott for reply.)

Quite a sharp debate followed the remarks of Mr. Angell. Most of the speakers were inclined to think that adulterations were not so bad as has been supposed. Glucose and oleomargarine each got a good word.

The only remaining paper having any medical interest was one by **MR. EDWARD M. HARTWELL**, of Massachusetts, a fellow of Johns Hopkins University, on

LAWS REGULATING DISSECTION AND GRAVE ROBBERY.

The history of anatomy in ancient and modern times was considered, especial attention being paid to the edicts of princes, the canons of the church and legislative enactments relating to it. The history of anatomy acts in England was given, and the New York act of 1879 was considered to be the germ of all subsequent American legislation regarding dissection and the desecration of sepulchres. The writer having compiled all the American acts on anatomy, and investigated the actual state of affairs in several medical schools, compared European and American anatomy in their legal, scientific, and economical aspects. The paper will prove a very valuable one to all interested in medical education or anatomical science.

The Association elected Francis Wayland President for the ensuing year; F. B. Sanborn, Secretary. The officers of the Health Department are: Dr. D. F. Lincoln, of Boston, Chairman; Dr. E. W. Cushing, of Boston, Secretary.

Correspondence.

IMPOSITIONS UPON MEDICAL PRACTITIONERS.

To the Editor of The Medical Record.

Sir:—I notice that the late conference on vital statistics has had under consideration, as is usual in such bodies, the propriety of doing justice to private medical practitioners for their public services in making reports on matters relating to the same, but hesitate to take any definite action. They do not even go so far as to make any allowance for stamped envelopes and other necessary stationery. This, certainly, is very significant of the kind of men who compose this commission, or, at least, of the ruling spirits of it. I do not know their names, nor do I care to know them; but feel assured that they are men whose professional services are not much valued by themselves or by the community in which they reside.

No other class of professional men have such impositions to bear at the hands of the public as ours. Our hospitals are fair exemplars on the one hand, and the health boards of our cities on the other. It is required of the hospital staff that they attend upon every case admitted to the institution, without reference to the ability or want of ability of the patient to pay for the service rendered. It is a well-known fact that there are patients in the hospitals of this city whose financial conditions are far beyond that of the surgeons or physicians who attend them; yet all that is required of them by the management is, that they pay punctually their weekly board, whether they occupy private rooms or beds in the wards. But these conditions are, after all, not so hard, for each member of the staff agrees to this regulation when he accepts the appointment, and is at liberty to resign whenever he sees fit. The injustice is visible only in that he is not allowed some fee in cases where the parties are abundantly able to bear all expenses, even those incident to the occupancy of a private room, with all the luxuries accompanying such occupancy; or that, by the patient's coming to the hospital, he is allowed the liberty of cutting off the physician or surgeon from compensation for his important services. The explanation, no doubt, will be that, unless the attendant thinks it worth while to remain under the circumstances, he can resign his position. The explanation is a practical one, but not one in which I am able to perceive the virtue which we have a right to look for among the higher principles from which these institutions of charity spring, and by which they are maintained. The parties of whom I speak neither need nor ask for this charity, but they take it because it is provided. They would take more were it allowable: would take not only their board, but also compensation for their sufferings, and would, perhaps, only think that equitable.

The poor the physician always attends cheerfully, the only recompense being the luxury of doing good. Those able to pay, but who do not pay, he will attend with his accustomed skill, no doubt, but with a sense of the imposition practised—a feeling that lies heavily upon his heart.

The other bodies which impose upon medical men are the health boards of our cities. The impositions from this quarter are two-fold: 1st, for statistical information only; 2d, for statistical information for sanitary purposes. Both are for public use, and not for the personal advantage of the physician. The first are the birth-certificates. This is clearly an imposition, and quite intolerable, and is of no more practical importance than to ascertain the amount of business done by each physician in that branch of practice. The law does not require the parturient woman to have a physician, or even a midwife of any kind. It is left entirely to her choice. A friend of the family, who is not a skilled midwife, may attend; a licensed midwife may attend; or a physician from out of the city, or from another county, may do so. To attend in a case of this kind, under the existing law, puts the physician in a position of grave responsibility, for upon him rests the establishment of the citizenship of the new member of the community, should that ever be called in question. This is a responsibility which no physician will willingly assume. His certificate of birth may come in evidence, but the responsibility should not rest with him. The parties most interested are the parents and the next of kin, which the law ostensibly provides for, but the health board rules differently.

We would suggest that this matter be left solely to the parents or the next of kin. We would make it obligatory upon them to make the registration; at the same time we would afford them every facility for doing so. We would suggest that in cities the police-stations be made a place of registration. In the country let the town clerk be the register both of births and of deaths; and let the record of these be sent finally to the capital of the state. Let it be remembered that for performing this service, for assuming, or, more correctly, for having imposed upon him, this grave responsibility, the physician receives no compensation; but, for neglecting this duty, he is liable to pay a fine. And should he make a report, it would most likely be incomplete; the name of the child left out, perhaps, or some other particular of the description omitted.

As to statistical information of a sanitary character, information which the physician alone can furnish, we object to giving the same without adequate compensation, just as strongly as the other. Although without reflection this might seem strange, it will seem less so when we state that the reports to the sanitary bureau are made not only at a loss of time and money, but often at the sacrifice of the reputation of the physician as a faithful follower and disciple of Hippocrates, and he suffers the loss of practice consequent thereupon. It is taken for granted that when a patient approaches his physician to make known and lay bare the ills of the body, as the spiritually sick may approach his confessor concerning the ills of the soul, his ailments shall be forever shrouded from the public gaze, and concealed under the veil of eternal secrecy. But this enactment requires of him that he shall lay aside this confidential character, and for the public good assume for the time-being the *rôle* of detective, making use of his profession as a detective of the public under the garb of taking measures for the public safety. This is well illustrated by requiring the physician to report all cases of contagious disease to which he is called, to the sanitary bureau. Should the case be one of variola, and occurring in a tenement-house or a flat—in any dwelling, in fine, in which there are several families living—the board of health would, according to its usual custom, have the patient removed—transferred without ceremony to the hospital specially provided for this disease. As a rule, the separating of the patient, even under these circumstances, from family and friends, without so much as saying "by your leave," is regarded as a gross invasion of private rights. The aggrieved parties are apt to feel more acutely the wrong which they conceive has been done them, when they learn that isolation has never yet in the history of this disease prevented its spread, and that vaccination, and that alone, is the preventive. For this revelation the physician is regarded as a traitor to his professional trust, is stamped with infamy, and is not likely ever again to practise in that family. These are families, too, let it be understood, which do not belong to the ignorant classes. If there be any difference in the relative social status of parties, they are most likely higher in the scale than the legislators who have concocted and passed this arbitrary law. The writer of this has lost from his practice a score of families for thus reporting contagious diseases in accordance with the requirements of the statute, and no explanation he could offer would suffice to set the matter right. I can recall one instance where, by reporting a case of smallpox, I was thus summarily dealt with. The patient was the wife of a young gentleman and the mother of two children. Incident to this case I lost also the medical business of four other families.

These reports are intended for the public good, and regarded as measures of safety to the health of the community; but they are, nevertheless, likely to result in every case to the detriment of the practitioner who makes the report. If, then, these reports are for the public good, the public should be willing to pay for the service. It should be paid for the same as legal fees are paid; for it would seem to the writer that the services of a physician—any service that he can render, either of a private or of a public nature—should be compensated for equally with an attorney for his services, if the party is able to pay. For certainly the services of the former are quite as necessary—in many cases, indeed, more indispensably necessary—than the services of the latter. During the current six months, bills for legal fees amounting to between $50,000 and $100,000 have been sent in by lawyers, all of which will no doubt be paid from the city treasury. These bills, too, are mostly for services which are incidental—extra services, not otherwise provided for by law.

A New York M.D.

September 6, 1880.

PHYSICIAN AND PHARMACIST.

To the Editor of The Medical Record.

Sir:—With great satisfaction I have read the articles in the Record trying to define the relative position of the druggist to the physician, and *vice versa*. Good can only come from a thorough sifting of the question, Is the druggist a help to the medical profession, or is his existence a drawback, or rather, is he a necessary evil?

The physician should bear in mind that there are two kinds of pharmacists, just as there are the educated medical doctor and the common quack, and act accordingly. The business of the druggist is to keep pure and unadulterated drugs. To be able to do so it is essential that he must be conversant with the different tests to detect the daily occurring adulteration of drugs; and in fact he must possess pharmacognostic knowledge of no mean degree. Now, how many of our so-called pharmacists do come up to the mark? In glittering pharmacies and in small shops around the corner only too often are found men, excellent business men it must be admitted, but who do not possess the first rudiments of a pharmaceutical education.

As we all know, little knowledge is dangerous in a physician, but it is eminently more so in a druggist. The surgeon who, in a dangerous operation, calls his professional brother to his aid, not trusting to his own judgment alone, or the doctor who exchanges views in consultation with his colleague, sends the next minute for his chloroform, ether, or Magendie's solution to the nearest shop. He does not stop to think that he stands an even chance of getting a Magendie's solution prepared with sulphuric or salicylic acid, inasmuch as the druggist may think it all the same as long as the solution keeps in his stock-bottle; or that he gets it prepared with Croton water, because the druggist reasons Croton is cheaper than aqua destillata, and just as good. Besides, the doctor does not want expensive medicine. The next neighbor druggist, who carefully prepares his Magendie's solution with aqua bidestillata, cannot be patronized, because he charges a few cents more per ounce, and if the patient pays for so dear medicine, what will be left, then, to pay the physician's modest fee?

The medical profession would do wisely to co-operate with the skilful and educated druggists to elevate the drug business to a profession, ridding the community of the ignorant and unscrupulous, and also, by devising proper legislation, create such safeguards that the dispensing of faulty medicines would be next to an impossibility.

The dispensing of medicines by the practitioner himself will do for the homœopath, but will never be adopted to any extent by the regular profession. First. Because very few physicians will be able to find time to attend to pharmacy or will trouble themselves making wafers, pills, capsules, ointments, infusions, etc. Second. They will find it both impracticable and expensive to keep a line of goods such as fresh ergot, digitalis leaves, leeches, syrups, bromine, etc., on hand. And third. Because very few physicians will know how to select a good and reliable stock of drugs, being at the mercy of the wholesale druggist, who generally is a far greater adept in the science of adulterating drugs than the average retail druggist.

As matters stand to-day, the first thing every physician ought to do is to prepare a list of the really trustworthy and educated pharmacists in the city or town in which he resides, and to insist upon his patients only patronizing such stores as he has found worthy of confidence. By withdrawing their patronage from the bunglers, and by discontinuing to prescribe patent medicines, these incompetent stores would soon be wiped out, despite the little counter-prescribing they may indulge in. Also, by all means let the public know which pharmacies are in the habit of dispensing horse medicines, and teach the public to discriminate between the competent pharmacist and the ignorant drug-dealer, whether he be found in a modest store in a side street or in a fancifully fitted up store on Broadway.

Respectfully,
F. L., *Drug clerk.*

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from September 5, 1880, *to September* 11, 1880.

Moore, John, Major and Surgeon. Having relinquished the unexpired portion of his leave of absence, will report in person to the Surgeon-General, in this city. S. O. 192, A. G. O., September 9, 1880.

Taylor, M. K., Capt. and Asst. Surgeon. His assignment to duty at Fort Concho, par. 2, S. O. 161, C. S., revoked. S. O. 176, Department of Texas, August 30, 1880.

Cronkhite, H. M., Capt. and Asst. Surgeon. Having reported in person at these headquarters, is assigned to temporary duty at Fort Sidney, Neb. S. O. 83, Department of the Platte, September 7, 1880.

Moseley, E. B., Capt. and Asst. Surgeon. The leave of absence granted him from Headquarters Department of the Platte, August 17, 1880, is extended two months. S. O. 187, A. G. O., September 3, 1880.

Reed, W., Capt. and Asst. Surgeon. To proceed without delay to Creedmoor, Long Island, for temporary duty with the United States troops at that point. S. O. 153, Department of the East, September 6, 1880.

Carter, W. F., First Lieut. and Asst. Surgeon. His assignment to duty at post of San Diego, Texas, par. 2, S. O. 161, C. S., revoked. S. O. 176, C. S., Department of Texas.

By par. 2, S. O. 190, A. G. O., September 7, 1880, the following changes are made, to take effect October 1, 1880:

The following named officers are relieved from duty in the Department of the East, and will report in person to the commanding generals of the departments set opposite their respective names, for assignment to duty:

Asst. Surgeon D. G. **Caldwell**, Department of the Platte; Asst. Surgeon J. H. **Patzki**, Department of the South; Asst. Surgeon B. F. **Pope**, Department of Dakota; Asst. Surgeon W. J. **Wilson**, Department of Dakota.

Asst. Surgeon **Frank Meacham** is relieved from duty in the Department of Texas, will proceed to Boston, Mass., and upon arrival report by letter to the Surgeon-General.

Asst. Surgeon R. H. **White** will report in person to the Commanding General, Department of the West, for assignment to duty at the United States Military Academy, relieving Asst. Surgeon **Henry Lippincott**, who, when relieved, will proceed to New York city, and upon arrival report by letter to the Surgeon-General.

Asst. Surgeons M. K. **Taylor** and J. H. T. **King** are relieved from duty in the Department of Texas, will proceed to New York city, and upon arrival report by letter to the Surgeon-General.

Asst. Surgeon W. **Matthews** will report in person to the Commanding General, Department of the Missouri, for assignment to duty.

Asst. Surgeon T. A. **Cuningham** is relieved from duty in the Department of Dakota, will proceed to New York city, and upon arrival report by letter to the Surgeon-General.

Medical Items and News.

Contagious Diseases — Weekly Statement. — Comparative statement of cases of contagious diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending September 11, 1880.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro spinal Meningitis.	Measles.	Diphtheria.	Small-pox.	Yellow Fever.
Sept. 4, 1880.	0	7	24	6	12	46	0	0
Sept. 11, 1880.	0	15	36	2	8	49	0	0

The College of Physicians and Surgeons.—The item under the head "The New York Medical Colleges," published in our last number, needs to be corrected. The regular winter course of lectures in the College of Physicians and Surgeons begins October 1st, and continues until nearly the 1st of May, after which the examinations for the degree of doctor in medicine are to be made. The commencement exercises will be held about the middle of May.

Progress of the Registration of Physicians.—Up to September 14th somewhat over a thousand physicians had registered at the County Clerk's office. There are, probably, nearly 2,000 more to register. Until the present week registration had been very slow, the number averaging ten or twenty a day. This week the doctors are going down in a very steady stream.

There is an ingenious arrangement at the office for getting half a dollar extra out of the profession. The clerk charges a quarter of a dollar for registration, a quarter for the affidavit, and another quarter for a printed and sealed certificate that the bearer has registered. This last is not essential, and the twenty-five cents is, we believe, twice the usual fee for administering an oath.

Dr. Buchanan, who ran away to Canada while under bail, has been caught and brought back to Philadelphia.

Dr. Sutton desires us to state that the woodcuts in his lecture, recently published, were copied from the *Chicago Medical Gazette.*

Malaria Mania.—The correspondent who signs himself "H" is reminded of the rule in the Record to the effect that no communications receive notice unless accompanied by the full name of the writer. The latter is not necessarily for publication, but as a guarantee of good faith to the journal.

The Surgical Treatment of Epistaxis.—Dr. J. G. Brownlee, of Doniphan, Kansas, writes: Reading Dr. Thurston's method of treating epistaxis, in your issue of 21st inst., calls to mind a case treated by myself some six months ago. I was called to see a woman (colored), æt. 28 years. Found her bleeding profusely from the nose; said she had lost three quarts of blood before my arrival; I tried different remedies without success. I then thought of using an ordinary condum in the same manner as we use the rubber bag in uterine hemorrhage. I sent immediately to the drug store and procured a condum and a syringe; I then took a Jacques' soft rubber catheter, placed it inside the condum, and introduced it up the nose till it passed the posterior nares. With the syringe I then injected the condum with ice-water, removed the catheter, and tied the end of the condum to prevent the escape of the water. The hemorrhage was immediately arrested and the patient had no further trouble. By this simple method I claim that any physician can control any case of epistaxis without the use of Bellocq's canula, or any other device for plugging the posterior nares.

Tuberculous Laryngitis.—Where there is great pain and dysphagia the following mixture, applied with a laryngeal brush, is recommended by Dr. E. Fletcher Ingalls. The relief produced by the application of this has given more satisfaction, says Dr. Ingalls, than anything else in the course of his professional life:

℞. Morph. sulph	gr. iv.
Tannin	gr. xxx.
Acid carbol.	gr. xx.
Glycerin	℥ j.

M.

M. Verneuil, Surgeon to La Pitié Hospital, and Dr. Charcot, chief physician of the Salpêtrière, have been made officers of the Legion of Honor.

Prof. A. W. Hoffman has been appointed Rector, and Professor Schroeder, Dean of the Faculty of the University of Berlin.

The Ingles Case and Sir William Gull.—The trial of the nurse Ingles for manslaughter, to which we have previously referred, brought out the full particulars of the unfortunate occurrence. It will be remembered that the patient, a woman aged 26, was under the care of Dr. Pavy, who had diagnosed her trouble as phthisis, associated with hysterical symptoms. The lung disease was not far advanced or very active, but there was considerable weakness, and she had a slight irregular febrile movement. The hysterical symptoms consisted chiefly in a disinclination to exertion and in complaints of vague wandering pains or weakness in the limbs. The *Lancet*, in commenting on the case, inclines to believe that they were evidences, not of hysteria, but of a chronic meningeal tuberculosis. Regarding the trouble as hysterical, however, it was thought that the patient needed an occasional "rousing." On July 5th she soiled her bed, and the nurse, thinking that cleansing and discipline might be united, had her walk to the bath-room. She was kept sitting in a bath of lukewarm water most of the time for an hour and a half. Dr. Pavy saw her four or five hours later and was "struck by her altered appearance." She was feeble, cold, and shivering, and made disconnected statements as to the treatment she had received, and cried and sobbed a good deal. Bruises were found on her body. Three days later symptoms of tubercular meningitis set in, and in a fortnight more she died. Autopsy revealed evidences of old and recent tubercular meningitis, with phthisical changes in the left lung. At the trial the nurse was adjudged, upon the evidence, to have been guilty of gross and culpable misconduct, and of hastening the patient's death. The only medical evidence for the defence was given by Sir Wm. Gull. He questioned the accuracy of Dr. Pavy's diagnosis, and was not inclined to think that the bath excited the tubercular disease or hastened the death of the patient. His evidence, on the whole, threw discredit upon Dr. Pavy, and, it is said, was decidedly without the lines of professional courtesy.

Great indignation, public and private, has been caused by Sir Wm. Gull's conduct When he received his degree of LL.D. at Cambridge, etc., he was greeted with a storm of hisses. He has, as yet, offered no explanation of his conduct.

Impacted Watermelon Seeds.—Dr. J. H. Straughn, of Lexington, Mo., writes: On August 3d I removed a pint of watermelon seeds from the rectum of a patient of mine. He had eaten the melons, seeds and all; the seeds were so firmly impacted that they had to be removed under chloroform.

New York Confectionery.—The statistics of the manufacture of confectionery in this city have recently been completed. The factories were found to number 310. The report states that the wholesale trade is active and thriving, but that the smaller manufacturers, who make and retail their own goods, complain of dulness in trade and small profits. These dealers allege that most of the large manufacturers adulterate their goods largely with grape sugar, glucose, terra alba or white earth, and other injurious ingredients, and can thus afford to sell their products for a less price than the small manufacturers pay for sugar. They also say that they cannot use these adulterations in their way of manufacturing, and would not if they could; that if the authorities continue to allow the adulterated goods to be sold as sugar candies, the honest manufacturers will have to leave the business or retail the adulterated goods of the large houses. The cost of granulated sugar by the barrel is ten and one-half cents, while that of grape sugar and glucose is four cents, and of terra alba one cent. They allege that the adulteration is from fifty to seventy-five per cent. of impurities, and in gum drops much more. They say that the consumption of these adulterated candies is the cause of more sickness and death among the children of this city than all the sewer-gas and dirty streets combined.

Treatment of Asthma.—In a series of lectures on this subject, by Dr. J. B. Berkart, Assistant Physician to London City Hospital (*Brit. Med. Journ.*), the view is advocated that asthma is not due to any mysterious derangement of the nervous system, as is generally taught. On the contrary, he says, it is a matter beyond question that asthma, with few, if any exceptions, proceeds from inflammatory changes of the lungs. In the vast majority of cases it arises in childhood as the direct continuation of catarrhal pneumonia, complicating whooping-cough, measles, and typhoid fever. In adults it is the sequel of bronchitis. These diseases inflict permanent changes on the lungs or chest, and give an anatomical basis to the subsequent asthma. When asthma declares itself there are always pathological changes, The most constant among these are deformities of the spine and of the thorax of various kinds. A similar variety of changes exists in the lungs.

There may be emphysema, or induration of the parenchyma; peribronchitis, with dilated bronchi; splenizations; congestions. It is to these various conditions that treatment is to be directed; and although they are irremediable, much can be done to give relief.

Syphilis the Cause of Rickets.—Professor Parrot, physician to the Hospice des Enfants Assistés, where he has had an immense experience in children's diseases, asserts very positively that the sole cause of rickets is hereditary syphilis. The position is defended as strongly as it can be. We doubt, however, if anything can prevent its being considered untenable and absurd.

A Dental School, with an infirmary attached, has been established for the first time in Paris.

Treatment of Infantile Cholera by Quinine.—Dr. Boing reports in the *Allgemeine medicinische Central Zeitung*, fifty cases of infantile cholera, treated chiefly by quinine, and all terminating favorably. From one to four grammes (gr. xv. to ʒ j.) were given at short intervals during the twenty-four hours, to children under four years of age. The diet is composed of milk and water boiled separately. Large quantities of wine are used, and occasionally, ether. One little girl, three years old, apparently moribund, took a pint of Tokay wine in fifteen hours.

Provident Dispensaries in England.—The practicability and usefulness of provident dispensaries in provincial towns has been illustrated by the success of that at Leicester, England. There is at this place a central dispensary numbering 25,000 members, and giving an annual income of $20,000.

A Defence of Oöphorectomy.—At a recent annual meeting of the West Somerset Branch of the British Medical Association, Mr. Lawson Tait made a defence of the operation of oöphorectomy, giving some interesting facts from his experience with regard to its *unsexing the patient*. Mr. Tait said that as the diseases for which the operation was performed had already unsexed the patient as far as child-bearing was concerned, and in many cases as far as marital functions also, this argument was futile. The operation often restored the sexual capacity previously destroyed. In this the operation had had, in his experience, exactly the opposite effect attributed to it in the argument he was discussing. As to its *destroying the sexual instinct and desire* in women, Mr. Tait said that no such consequences resulted. Two of his patients operated on were married ladies in good position, and they stated that it made no difference whatever in their marital relations; all his patients stated that it made no difference in their feelings for the other sex. As to alleged *alterations of voice, appearance, abnormal growth of hair, tendency to obesity*, etc., it was denied that they occurred. The possibility of a *criminal abuse of the operation* seemed too remote for any consideration. It seems barely possible that enthusiastic oöphorectomists will, in time, advocate their operation as an aphrodisiac measure or a cure for sterility.

The Medical Night Service in Paris reports, for the second quarter of the year 1880, 1,421 visits. Of the calls, those for men were 35 per cent.; for women, 51 per cent.; for children, 13 per cent.

The Value of Vivisection.—In *Scribner's Monthly* for September Dr. H. C. Wood replies to the arguments of Dr. Leffingwell against the value of vivisection. Dr. Wood's article is a dignified and forcible one. We hope it may effectually counteract the influence of Dr. Leffingwell's ill-judged attempt to help physiology by advocating the regulation of vivisection.

Texas Fever has been discovered by Prof. James Law among some of the cattle at Oswego, N. Y.

A New Building for the Harvard Medical School.—The Corporation of Harvard University have secured the ground for a new building for the medical school. The lot contains 33,000 square feet, and is situated on the "back-bay lands," about half way between the city and the Massachusetts General Hospital. The location is said to be a very convenient one in all respects. It is hoped that the building will be finished by 1882, so that the centennial of the school can be celebrated in it.

An Ethnological Phenomenon.—Dr. Harvey L. Byrd, in the *Independent Practitioner*, states that in an experience of over thirty years he has always found a dark or blackened condition of the genitals in persons of mixed Caucasian and negro blood. In the mulatto, for example, the scrotum of the male and the vulva of the female will be found to be as dark as the darker of the two parents of the individual. The characteristic continues throughout life. It may be of some medico-legal as well as ethnological interest.

Buffalo State Asylum for the Insane.—Dr. Judson B. Andrews, of Utica, has been chosen superintendent of this asylum. "He is," says the *Buffalo Medical and Surgical Journal*, "a gentleman of extensive experience, of wide culture, and rare administrative ability." Dr. Andrews will deliver a course of lectures on nervous diseases at the Buffalo Medical College.

Dr. J. E. Michaels has succeeded Prof. Miles in the Chair of Anatomy, University of Maryland.

Resignation of Professor Klebs.—It is announced that Prof. Klebs, of the Chair of Pathological Anatomy at the University of Prague, has resigned. The cause of his so doing is the refusal of the faculty to give him larger opportunities for experimental investigation at the General Hospital.

TYPHOID FEVER.

A Clinical Lecture Delivered in the Amphitheatre of Bellevue Hospital, September 17, 1880.

By AUSTIN FLINT, M.D.,

PROFESSOR OF THE PRINCIPLES AND PRACTICE OF MEDICINE IN THE BELLEVUE HOSPITAL MEDICAL COLLEGE, NEW YORK.

Gentlemen:—To-day I will present to you a case which I know will interest you, and I will state at the outset that it is one of typhoid fever. It may be a question whether it is not one of typho-malarial fever. Our suspicion of the existence of this is obtained principally from the previous history of the case. At the present time we are seeing cases of typhoid and of malarial fevers combined. These two fevers may be combined in a given case in varying proportions. In the present case an inference of the coexistence of these two diseases is based rather upon the history given by the friends of the patient, and also because she has been treated for some time pretty largely with quinia.

I will first of all ask your attention to the answer of this question: "On what grounds do we conclude that this patient has typhoid fever?" The patient is a young subject, twenty-seven years of age, Annie O'D——, and was admitted to Bellevue Hospital, September 7, 1880. I will confine my remarks for the present to the above question. This patient was confined with a still-birth ten weeks before her admission. She recovered from that, and, as far as we can learn, her present illness began about three weeks before she entered the hospital; she had been confined to her bed for about two weeks previous to her admission. Now this slow development of the disease is one point in favor of typhoid fever. Typhoid develops in this slow way—so slowly that the patients cannot tell exactly when they began to be sick. Usually it is from four to ten days from the beginning of the disease before the patient is obliged to take to bed. I am in the habit of calling the time when the patient takes to bed as the time when the disease begins, as the prodromic period is likely to vary considerably. This slow development of the disease is characteristic of typhoid fever; malarial fever and other fevers do not have this long prodromic period.

Since her admission she has at times manifested an inclination to cough, and upon examination, a little bronchitis was found to exist; this also goes with typhoid fever. She complained of pain in the abdomen, and at that time her bowels appeared to be constipated. It was ascertained that she had been bleeding at the nose—epistaxis—a trifling event when taken alone, but when taken in connection with the other symptoms which are present, it is of considerable importance. Epistaxis not infrequently occurs in the early part of typhoid fever. At the time of her entrance to the hospital her temperature was found to be 103°, and on the following morning it was 104°. In the evening the temperature was the same, 104°, pulse, 100. On the next day in the morning her temperature was 103°. No medicinal treatment was entered upon. She was deaf and the deafness could not be explained as being due to the administration of quinia; so we have another symptom of typhoid fever. I have known almost complete deafness to occur in typhoid fever. On the day she entered the hospital she had had two movements of the bowels. They were loose and of a yellowish color. Of course this alone would be of little or no value, but taken in connection with other symptoms which were present in her case, it is of diagnostic value. On the 9th of September her temperature was 103° in the morning. She was now placed upon half an ounce of whiskey every four hours, together with milk as a diet. She has also had aromatic spirits of ammonia, which, though not a very potent remedy, is still a remedy of some value. The urine was examined, but nothing of importance was found. Upon examination of the abdomen externally it was found somewhat tympanitic, owing to the accumulation of gas in the intestines, and there was distinct tenderness in the iliac region upon the right side; this was diagnostic. We looked of course for the eruption, but the eruption was not present then, nor has it been present since. The absence of the eruption, however, is not very infrequent in cases of typhoid fever. The patient has been under observation since September 7th, during which time there has been a typhoid condition of the mind—a passive delirium, attended with some incoherency and an indifference concerning persons and things. She has had all along the same appearance which you see now in her physiognomy. This appearance is not as marked now as it has been in the ward, owing to the excitement of the mind of a woman upon being brought into the presence of so many gentlemen; but, after all, she manifests very little disturbance.

These, then, are the points by which we may make the diagnosis of typhoid fever in the case before you; the slowness of its development, the existence and the continuance of the fever, with not much variation between the morning and evening temperatures, not so much oscillation as is found in malarial fever, the occurrence of epistaxis early in the disease, a pulse with little fluctuation, the passive delirium, the dulness of the intellect, the existence of tympanitis, the loose passages from the bowels, and the existence of bronchitis.

The husband of this patient stated, that in the house whence she came, there exists an unpleasant condition of the sewers. We have also learned, that, in the same house, another individual has been attacked much in the same way and with apparently the same disease as the patient before you. So here are facts which seem to show the source of the disease to be defective sewerage. So much for the diagnosis and causation.

This patient has now been in the hospital ten days, and she was ill two weeks before she entered the hospital; that is, was confined to her bed, so by this estimate she is now in the twenty-fourth day of the disease. With regard to the duration of typhoid fever, I would say, that it is a self-limited fever. It has a law of duration, yet the duration varies within tolerably wide limits. If the disease be of short duration, it will last not much less than fourteen days. The longest time I have ever known it to continue is ninety days, and that was in a case in this hospital, years ago. In the case before us it is evident we have not reached the end of the fever, and it is now about the twenty-fourth day.

I will now pass to another very interesting aspect of the case, and I have so much matter that I am a little embarrassed as to how to present it to you. There has been made a record of the temperature, respiration and pulse of this patient for nearly every hour since she entered the hospital. It would be tedious to read all this, and I will therefore endeavor to abstract those facts which are of especial interest in reference to treatment. The interest of these facts has relation especially to the antipyretic treatment of typhoid fever and the importance of the application of cold to the surface of the body as an antipyretic measure. The antipyretic treatment of fevers has, in the last few years, elicited much interest, and has apparently wrought an important change in practical medicine. Fevers may be diminished in several ways. A large dose of quinia will do it in some instances, but it cannot be relied upon. Quinia has not been employed in this instance. More reliable is cold applied in the form of the cold bath, the cold sheet, or the wet pack. The cold bath was first used, but as it is a troublesome method and frequently produces a nervous shock to the patient, it has been found, on this account, desirable to use a substitute for it. I believe we can procure the same results from the cold sheet, and by that I mean the wrapping of the body in a wet cloth and sprinkling with cold water. The wet pack although an antipyretic measure, does not accomplish much through the agency of cold, as the action of the cold is continued only for a few minutes, the body being wrapped in a wet sheet and a thick, dry covering placed over all: the good effects obtained from the pack is through other means than by cold. There is still another way of applying cold to the surface of the body, which is of all means the easiest, viz., sponging the entire surface with cold water. If the sponging be practised thoroughly, it is quite effective. Where the circumstances will admit, you can denude the whole body and sponge it thoroughly, or where this is not admissible, you may unrobe a portion of the body, and after this another part, and so on until the entire surface has been sponged. The object in general terms is this: where there exists a hyperpyrexia, that is, a temperature of 103°, or over, some method of applying cold is to be employed. The patient should be carefully watched and perhaps given a little alcoholic stimulus. After the cold has been applied for a time, the patient should be placed in bed and the temperature taken, so as to determine what effect, if any, the bath has had. The temperature of the body often falls for some time after the application of cold has been suspended. It is desirable to bring the temperature down to 101° or lower. When the temperature again rises, application of the cold is again desirable, under the theoretical view, that much of the danger is in some way dependent upon the degree of the fever, and although we do not abort the fever, we abate it. I fully believe in this, and I believe it to be a very important progress in the treatment of essential fevers and certain acute inflammations. Now let us see, this is a modern treatment, and yet it is the revival of a very old treatment. Nearly a century ago, an English physician, Currie, recommended this treatment, and if you have the opportunity of reading his work I would advise you to do so, for it is a work which bears the evidence of great honesty. He claims, that in a large majority of cases, he could arrest continued fevers. He employed cold water in the form of the douche, or cold affusion. I suppose, perhaps, the apparent severity of this measure led to its becoming obsolete; but Currie anticipated what we recommend to-day. It is further interesting to note, that he devised an axillary thermometer, which was bent so as to be placed under the arm; in fact, he anticipated the modern use of the thermometer, as well as the use of cold in fevers.

Now let us see what we can find, in the history of this case, that is instructive in the employment of cold in the treatment of this disease. I would state that half an ounce of whiskey every four hours, and afterward the same quantity every three hours, and now every two hours, has been given; and that, in connection with baths and a milk diet, has constituted the treatment. She has also taken aromatic spirits of ammonia, which, however, is not a very potent remedy. I will try not to be tedious, but limit myself to points which are instructive.

Well, she had a sponge-bath September 10th. This was employed about twelve o'clock (noon), and at half-past twelve her temperature was 103¼°. An hour before the bath, at eleven o'clock, it was 103½°, a reduction of only one-fourth of a degree. At forty-five minutes past one, another sponge-bath was given, and at two o'clock her temperature was 103¾°; no result thus far. At 2.45 P.M. the temperature was 104°, and at three o'clock the patient was placed in a cold pack for an hour. At four o'clock in the afternoon, her temperature was 102½°; the reduction evidently being from the effect of the cold, because the temperature would naturally increase rather than decrease in the afternoon.

At ten o'clock on the morning of the 11th her temperature was 103¼°; a sponge-bath was given, and at 10.30, her temperature was 102°—a sudden reduction of a degree and a quarter due to the application of the sponge-bath. At one o'clock, her temperature was 102¼°, and at four o'clock her temperature was 104°. A sponge-bath was given and at 4.45 her temperature was 102°, a reduction of two degrees. At seven o'clock, her temperature was 104°. Ten minutes after seven a sponge-bath was given, and at 7.40 P.M., her temperature was 103°. At ten o'clock in the evening, her temperature was 104°; she was given a sponge-bath but its effect was not recorded.

September 12th, at 1 A.M., her temperature was 104½°. She was given a sponge-bath, and at 2.30 A.M. her temperature was 104°; practically no effect. These figures are instructive from their negative, as wall as from their positive evidence. How long the bath was continued is not stated. At three o'clock she was placed in a cold pack for an hour, and at four o'clock her temperature was 102½°. At seven o'clock her temperature was 103¼°, and then a sponge-bath was resorted to, and at eight o'clock her temperature was 102½°; it rose again however, and at ten o'clock was 103°. A sponge-bath was given and the temperature fell to 102¼°.

Now I come to the record of September 13th. At ten o'clock in the morning her temperature was 103¼°. At 10.50 A.M. it had fallen one-fourth of a degree. At one o'clock, her temperature was 104°; a sponge-bath reduced it to 103½°. At 3.45 P.M., her temperature was 105½°. At 5.30 P.M. the patient was placed in a cold pack, and at 6.30 P.M. her temperature was 103¾. At nine o'clock, her temperature was 104½°. A cold pack was given, and at ten o'clock it was 102½°. At twelve o'clock the temperature had risen and the cold pack was resorted to, but with what result is not recorded.

September 14th, 2 A.M., temperature 104°, two hours after the cold pack on the previous day. Cold pack was administered, and at six o'clock her temperature was 103°, illustrating that the decline of temperature after the application of cold does not always take place immediately.

September 15th, at midnight, her temperature was 104°. A cold pack was given about one o'clock in the morning, which reduced the temperature to 103¼°. At 4 P.M., September 15th, her temperature was 103¼°. A cold pack was administered, and at seven o'clock it was 103⅛; only a slight reduction.

September 16th, at one o'clock in the morning, her temperature was 103¼°. A bath was given, and by 6 A.M., the temperature had fallen to 102½°. On the 16th, finding her respiration somewhat quick (forty-two to the minute, while the pulse was only a hundred), I examined this patient, believing this disproportion between the heart-beats and the respiratory movements to indicate some pulmonary difficulty. I suspected pneumonia, which, however, was somewhat inconsistent with the temperature; but upon examination of the chest, I found evidences of bilateral œdema in the posterior aspect of the lungs, which was due to the gravitation of the blood into that part from the continued recumbency upon the back. The evidences of this were fine bubbling râles. This condition pointed to rather an important point in the treatment of typhoid fever, namely, not to permit the patient to rest upon the back all the time.

Now we come to the 17th of September, and that is to-day. Her temperature at two o'clock this morning was 102°; at five o'clock, 102°; at eight o'clock 102½°; and at 11.45 A.M., 103°. Thus far to-day there has been no application of cold for the reason that there has been no hyperpyrexia. The temperature has been under 103°, with the exception of 11.45 A.M., when it was at that point.

Now, gentlemen, you will see by these details that reduction of temperature does not always follow the application of the sponge-bath, but that very generally the wet pack has reduced the temperature one or two degrees. Perhaps this has not been accomplished quite as fully as we might desire, but the febrile condition has been kept down within the limits of hyperpyrexia, namely, at a temperature of about 103°. The treatment, aside from this, please bear in mind, has consisted of alcohol as a sustaining agent, with milk for diet, and except in those cases where there is a repugnance to milk, this, as an article of diet, is to be preferred.

DIABETES INSIPIDUS,

WITH ATROPHY OF OPTIC NERVE AND EXTREME ENLARGEMENT OF THE LIVER.

A Clinical Lecture delivered in Rush Medical College, Chicago.

BY NORMAN BRIDGE, M.D.,

LECTURER ON THE PRACTICE OF MEDICINE.

THIS poor woman comes to us to-day for relief from some of the more annoying of the many symptoms of disease with which she is afflicted. On seeing her I recognize an old patient. She was sent to my clinic over three years ago by Prof. E. L. Holmes, for an examination for renal disease. She had sought Prof. H. on account of loss of sight in one eye, and he had discovered atrophy of the optic nerve. On examining her urine she was found to have diabetes insipidus. She remained under treatment about a month, and then disappeared, since which I have not seen her till to-day. At her former visit she related (and confirms to-day) that she was about thirty years old, and had always had good health until her first marriage, which occurred eleven years before. Two years, or a little more, after marriage, she contracted syphilis from her husband. She bore two living children soon after marriage, and subsequently had three or four miscarriages. Her last child, born prematurely, was delivered two years before she came to the clinic. Six months after this confinement she began to void abnormally large quantities of urine. She had steadily grown worse in this particular, till at the time of her visit she declared she passed each night a large chamber-vessel twice full of urine, and as much in proportion during each day.

She had commenced to get stout as soon as the diabetes began, and had become quite obese. Her general physical appearance has not changed since her first visit here. She is short of stature, but probably weighs two hundred pounds.

Two months before she consulted Prof. Holmes she had noticed a failure in the sight of her left eye. In a few weeks the eye had become entirely blind and the optic nerve atrophied.

At that time she had a poor appetite, and her temperature was slightly above the normal. The urine had a specific gravity of 1003, and of course contained no sugar; neither did it contain albumen; the microscope revealed nothing abnormal in the specimen. There was no œdema in any part of the body.

She now says that during her absence there has been no amelioration in her condition in any way. She has continued to void enormous quantities of urine without interruption, and to be beset with the same overpowering thirst she complained of years ago. Her tongue has a dark coating, and is dry, as you see. She has anorexia, and occasional vomiting and diarrhœa. She says she has had for many months past a severe headache much of the time, and that it has occurred at all hours of the day and night. She is not certain, however, that it is worse in the night than in the daytime. She tells us of another symptom, which she says has been present a good deal of the time since we last saw her—that is, fever. Implicit reliance should never be placed on such a statement, for this is a matter in which a patient may easily be mistaken. No one is certain to be a reliable judge of whether he himself is feverish. But the thermometer, under this woman's tongue, registers 101° F., so her statement may be correct, and surely the appearance of the tongue is not surprising. The abdomen is distended with gas, and tympanites is everywhere apparent except over the region of the liver. This organ projects two inches or more below the borders of the ribs, and has a hard, regular outline; it is considerably enlarged.

A prominent feature of this case is the symptom of diabetes. Absence of emaciation, notwithstanding the presence of fever, convinces us that sugar could not be present in the urine. No patient could have such an experience with saccharine diabetes without emaciation. Diabetes insipidus, then, is the name we naturally apply to this disorder, although our patient has important morbid conditions not necessarily belonging to that disease.

The nature of diabetes insipidus is a matter of some uncertainty. It usually is not a disease of the kidneys, unless a functional disturbance of these organs is a disease of them. The polyuria is similar in character to that which attends certain temporary disturbances of the nervous system, as hysteria, sick headache, or a fit of some disturbing emotion. These disturbances we know to be frequent, evanescent, and harmless. The kidneys simply cast out from the blood a quantity of water in excess of the normal limit; the solid constituents are little or not at all increased, and no abnormal substance is present. In cases of true diabetes insipidus, on the contrary, there is usually an increase in the total amount of solids excreted, particularly of urea, but this can hardly be said to be a distinguishing feature of the disease. Diabetes mellitus is always distinguished by the presence of sugar in the urine.

There are certain conditions of disease of the kidneys that produce a slight hydruria; these are chiefly the fibrous degeneration known as contracted kidney, the amyloid degeneration, and the rare affection hydronephrosis.

The excessive thirst and polydipsia are not the cause of diabetes insipidus, but rather the consequence. The patient drinks because his blood is impoverished in its water. Some analyses of the blood of these diabetic patients have shown it to be abnormally concentrated. The frequent reproach put upon these patients, then, that they prolong the disease by their intemperate imbibition of fluids, is as unscientific as it is cruel. The quantity of urine sometimes expelled is fabulous. Ten gallons has been known to be voided by a single patient in twenty-four hours.

With the great increase in quantity there is always a corresponding lowering of the specific gravity. The urinometer often registers as low as 1001, and the specimens are pale, nearly devoid of the usual urinous odor and color and acid reaction; they contain no abnormal ingredient.

Curiously, the general health and strength of these patients is usually not much disturbed. They maintain their normal weight, eat freely—sometimes inordinately. Where the total amount of urea excreted is above the normal and no emaciation occurs, an increased appetite should not occasion surprise. What are the causative lesions of this affection?

The evidence points to the nervous system as the seat of the mischief. A number of *post-mortem* examinations have revealed gross morbid changes in different parts of the brain, but most in the medulla oblongata and the region of the fourth ventricle. In a few instances injury to the skull, and tumors in different parts of the cortex of the brain, and chronic diseases of the spinal cord, have seemed to act as causes of this disease. Of course, with such various lesions of the nerve-centres we have a various and formidable array of nervous symptoms. In a few cases cataract, and in a few atrophy of the optic nerve, have been recorded. Degeneration of the solar plexus and various diseases, chiefly cancerous, of the liver, have been known to attend diabetes insipidus, but whether as cause or coincidental condition is not known.

Long ago it was found, in experimenting upon animals, that irritation of the floor of the fourth ventricle might cause diabetes mellitus. Brown-Séquard found that irritation of a point just above and anterior to this caused diuresis without sugar. The results of these experiments seem to find a correspondence in clinical observations. Lesions have been found in cases of diabetes insipidus in the same part of the brain where in the vivisections artificial irritation induced hydruria.

Syphilis occasionally produces deposits of morbid material in the brain, chiefly in the form of gummatous tumors. Some of the cases of brain-lesion in diabetes insipidus just referred to were of this character, and the suspicion is natural that in the case before us a lesion of the same sort exists. This suspicion is strengthened by the eye-symptoms present in this case, and the neuralgia, as well as the history of her specific infection.

A growth in the brain, or a degeneration, or other morbid change capable of inducing diabetes, might easily cause other nervous symptoms. Paralysis of certain muscles might ensue if the lesion involved the origin of motor nerves supplying them, or organs of special sense might be disturbed in their function. Certain nerve-fibres of sight are known to originate near the vital spot in the brain already referred to.

Now, this patient has had, besides the symptoms of diabetes insipidus, severe headache that cannot be charged to the functional disturbances of the system that usually cause headache, or to the diabetes *per se*. She has had various neuralgic pains of other parts of the body that can hardly be induced by rheumatism, and she has atrophy of an optic nerve. She gives a history of syphilis which is confirmed in some degree by frequent miscarriages.

A specific deposit in the neighborhood of the fourth ventricle of the brain could rationally produce many or all the symptoms we have referred to. That such a deposit exists we cannot now demonstrate, but the suspicion of its existence is made plausible by the enlargement of the liver. This may be due to subacute inflammation of the liver, and the slight fever lends force to this view. But the known specific history makes it difficult to avoid the suspicion that the enlargement is due to a gummatous deposit in the organ.

Can treatment benefit this woman? It is to be remembered, so far as the diabetes insipidus is concerned, that it rarely kills anybody. Patients are often destroyed by the lesions that induce the diabetes, as this patient probably will be, but the hydruria is comparatively harmless. No treatment for the latter has been generally efficacious. The plan of withholding fluids in true diabetes insipidus is always unsuccessful, as might be expected.

Tannic acid has been used with a hope of causing an astringent action, and thereby checking the drain. Some slight success has resulted.

Ergot, which of late has been employed whenever it is desired to cause contraction of capillaries, has been tried in diabetes insipidus. As renal congestion in some guise is supposed to make the diabetes possible, this would appear to be rational practice. The experiment has been attended with good results —not a uniform success, but enough to encourage us to further use of the drug.

If our surmise of the specific nature of this woman's trouble be correct, can anything be gained by antispecific treatment? Yes, probably something; but not all, nor perhaps much. I suppose it is now concluded that antisyphilitic treatment is impotent to remove far-advanced gummatous masses, or amyloid degeneration from the body.

If such were the case, this patient should not now be in this deplorable condition; for she tells us that since her former visit to us she has taken large doses of iodide of potassium almost continuously.

So far from any improvement, she has grown worse. Nevertheless, we shall prescribe her moderate doses of this drug, with ergot; and as she has fever, we shall prescribe quinine or cinchonidia in moderate doses, with opium sufficient to control pain.

NOTE.—This case was watched as an out-patient. The liver continued to enlarge, the fever grew worse, and was maintained for two or three months. Œdema of the lower extremities came on with ascites, and large ulcers formed on the legs.

Aspiration of the abdomen was performed, and a small quantity of fluid removed. She gradually improved, the fever abated, the œdema grew less, and the ulcers healed, but the size of the liver remained the same. The diabetes decreased a very little during the fever, to return, bad as ever, when the latter ceased. The patient died eight months after the above remarks were made, and during Dr. B.'s absence from the city.

CERVICAL PACHYMENINGITIS.

The Detailed Histories of Three Cases Occurring in Children.

By V. P. GIBNEY, M.D.,

OF THE HOSPITAL FOR THE RUPTURED AND CRIPPLED, NEW YORK.

(A paper read June 17, 1880, before the American Neurological Association.)

At the meeting of the Association in 1878 I presented an incomplete history of a case of cervical paraplegia, the lesion of which it was very difficult to determine. Since that time the case has progressed to recovery, and its developments have, I think, sufficiently cleared up the diagnosis to justify me in including it in the present paper.

Another case, the third of my list, has been presented incompletely in a paper on this subject before the New York Neurological Society, December 2, 1878.* This case is now a complete one, and is hence likewise embodied in this paper.

Case I.—*Apparently of traumatic origin—Intermittent torticollis during the irritative stage—A paralysis yielding promptly to treatment—Relapse of paralysis of eighteen months' duration—A stage of contracture—Spontaneous recovery with a permanent torticollis remaining.*

Jennie F——, aged seven years, came under observation first in the out-door department of the hospital, May, 1877, at which time she was wearing a plaster-of-Paris jacket and head support of the same material. This had been applied in the January preceding, when, it appears, she was first subjected to any treatment, although it is stated that for two years at least she had complained of pain in the head and cervical spine; her neck had been stiff at times, and her sleep had been disturbed by paroxysms of pain radiating about the occiput and down the spine. All these symptoms took their origin, it was believed by the parents, in a twist her neck got between the rounds of a chair.

The diagnosis of vertebral caries had been made at one of the college clinics, when the plaster-of-Paris was applied, and as the encasing was so complete when the patient first came under our own observation, this diagnosis was accepted without removing the plaster and subjecting her to an examination. This was deferred until we could make a removable apparatus. It was on June 26th that our apparatus was applied and a more careful examination instituted.

The head was in a bad position—rotated and hyperextended—yet there was no angular deformity of the spine. A note was made August 22d that the neck had straightened "like magic," and that as there was no deformity or arrest of normal movements, the diagnosis of Pott's disease must be incorrect, the more especially as there was marked tenderness on pressure over the spinous processes of the cervico-dorsal vetebræ. A fly-blister was ordered for this region, and belladonna, gr. ¼, prescribed for internal use.

In September there was a little resistance to complete rotation and extreme extension. It was thought that this would pass off soon, but in February, 1878, there was a return of the torticollis, and the area of tenderness embraced the muscles on either side of the spinal column.

March 8, 1878.—She is admitted to the hospital, a wretchedly nourished child, able, however, to stand and walk very well. The head deviates to the right, and the spinal column appears to be quite stiff, especially in the cervical and upper dorsal regions. The periosteum over the spinous processes of the tenth dorsal and the first lumbar vertebræ appears to be thickened, and this is all that can be construed into a vertebral prominence. There is no arrest of normal movements here, and there is no pain on concussion. The sterno-mastoid right side is contracted, and considerable pain accompanies any effort at overcoming this contraction. The ganglia on both sides of the neck are perceptibly enlarged, the shoulders droop forward, and efforts to restore them to normal position cause pain. Auscultation of the thorax is attended with negative results. The head support is reapplied, not, however, under the belief that any caries of the vertebræ exists. A tonic is administered.

26th.—Over the trapezii muscles there is some induration and a little discoloration of the skin, but as yet no deformity of the spine.

April 15th.—Posterior cervical region very tender, and a fly-blister is applied this evening.

April 19th.—The tenderness is unrelieved, and the infiltration is rather increased. The stiffness of the neck continues. She cannot be induced to raise the arms from the side without crying, and cervical paraplegia is imminent. Ext. ergot, fl. ʒ ss., and potass. iodid., gr. v., three times a day, ordered.

April 23d.—Slight improvement as to the pain and tenderness, yet the paresis of the upper extremities is quite marked, and the nurse reports that the patient has not been able to feed herself since the 17th.

April 24th.—While walking across the floor this morning she totters so, and is so feeble, that she is immediately placed in bed, and here she lies in one position, crying if moved. There has not been any vomiting; there is no exaggeration of the reflexes. Her pulse is 100, respiration 27, and temperature 99¼°; she is thin to emaciation. Her evening pulse is 100, and temperature 101°. Paralysis of both superior and inferior extremities is almost complete; yet there is no rectal or vesical disturbance.

April 25th, A.M.—Pulse, 90; respiration, 28; temperature normal. Doses of the ergot and the iodide doubled, making ʒ i. of the former and gr. x. of the latter three times daily.

April 26th.—Decided improvement in every particular. She moves the superior and inferior extremities quite freely, and the spinal tenderness as well as the neighboring infiltration has disappeared. The child takes milk quite freely.

April 27th.—Patient out of bed to-day. Continue the medicine in same doses.

April 29th.—To all appearances perfectly well, the movements at the neck being free and without pain. The mother, much against our will, removes the child at this date.

June 20th.—In company with Dr. Putzel, of this city, I visited the patient at her home in Elizabeth Street, and found her bolstered up in a chair, head inclining forward and to the right side. She sits motionless, and is in great dread of being moved. There is complete motor paralysis of both superior and inferior extremities. When the fingers are passively extended, they become involuntarily flexed after a few seconds, and thus remain. By tickling and by aid of a pin a moderate degree of anæsthesia of dorsal and palmar aspects of forearms and hands is recognized. There is marked atrophy of both deltoids and of other muscles about shoulder and arm, all symmetrical. Those of the forearm show very little atrophy.

---

* Published in this journal January 4, 1879, p. 20.

On passively raising the arms to a right angle with the body, the child complains bitterly of pain at the shoulder. The mother says that of late passive movements have caused pain down the forearms and in the fingers. The skin is not cold subjectively or objectively. Tenderness is very marked over the spinous processes, from the second cervical vertebra to the mid-dorsal, but does not extend farther than one inch to either side of the processes. No prominence or depression can be detected in this region, and the muscles seem free of any inflammatory process. It is with much difficulty that the chin can be raised and head restored to the erect position, the child referring the pain to the nape of the neck. As soon as the support of one's hand is removed, the head falls forward to its accustomed position. No disturbance of the special senses can be discovered, no facial paralysis. The pupils are normal, and respond well to light; her mind is unimpaired. There is never any headache except an occasional frontal headache, and this follows a crying spell. Her pulse is 132, rectal temperature, 103°. There is not, nor has there been, any disturbance of bladder or rectum The bowels move naturally once every day.

The muscles of the lower extremities are not atrophied; they feel comparatively firm to one's hand, and the child can flex and extend the thighs, legs, and feet with moderate force, yet she is unable to stand. Occasionally the great toe is drawn in moderate hyperextension. The knee and the foot phenomena are very marked, the epileptoid tremor exhibiting beautifully, though tickling the soles excites very little reflex action. No anæsthesia. This relapse came on about ten days after leaving the hospital (about May 10th), and has continued to the present time.

August 24, 1878. –My friend Dr. L. Emmett Holt visits the patient for me, and finds her in essentially the same condition as is recorded in preceding note. He learns that a member of the staff of the Out-door Department of Bellevue Hospital is treating the case now with extension apparatus attached to the head, traction being made by weight and pulley. Faradism is also being employed.

November 29th.—Visited again by Dr. Holt, who finds that the head apparatus, as also the faradism, have been discontinued. For nearly three months she has had no medical attention whatever. Her general appearance is better now than it was during the summer. She eats well, and her bowels are reported as regular; no bladder disturbance as yet. The position of the head is unchanged, and the paralysis is just as great; besides, the atrophy is to all appearances greater about the arms and shoulders. The spinal tenderness is not so marked, yet there is infiltration on either side of the spinal column, giving a doughy sensation to one's fingers. Occasionally now, as the child lies quietly on the sofa, shooting pains are felt in the arms and fingers. Passive movements cause pain as before, and pressure over the brachial plexus excites pain. The inferior extremities have become more powerless, yet, if the limbs be raised from the sofa, the child can flex and extend feebly. She is not able herself to raise either limb from the sofa. Reflexes are still very marked.

February 26, 1879.—To-day I visited the child and the same condition prevails as that above described, with the following exceptions: the flexors of the forearms are markedly contracted, the flexors of the fingers likewise, especially those of the little finger. Voluntary power is slightly increased in arms and fingers, yet this is so slight that it is hard to estimate. The atrophy seems to have slowly continued, all the while symmetrically. The muscles of the forearms are hard and small; the wrists are hyperextended, and the fingers flexed, giving the typical *main-en-griffe*. Inferior extremities are rigid in tonic extension most of the time. No cerebral disturbance; no difference in the pupils; no loss of appetite. Sensation is a little impaired; still no treatment, and cleanliness is sadly neglected.

December 21, 1879.—After eleven months I make another visit, all made purely for observation. The child does not occupy the sofa, and on my enquiring as to her whereabouts the mother informs me that Jennie has gone to Sunday-school. It is a bitter cold day, and while waiting for her return I learn that early in the spring, while getting her up one day to change the clothing, it was observed that she moved the limbs, and on attempting to stand this was found possible. From this time forth power rapidly returned, and in a few weeks she was running about the house as actively as any one. She gained flesh during the summer, and power returned to the hands and arms. There has not been any pain and no signs of relapse. She has been attending school since September.

By and by she comes bounding into the room, as fine a specimen of health as one cares to see. The extremities are bared and submitted to a thorough examination. All the movements at shoulder, elbow, wrist, and finger joints are executed with perfect ease and with normal force; the biceps stands out well, as do the deltoid and other muscles. She executes various fine movements with the fingers, and the thenar and hypothenar eminences, as also the interossei, are well developed. The muscles of the inferior extremities are as strong as or stronger than those of the superior. The different tests causing her to bring into action the various groups of muscles show a perfect recovery. Measurements of the extremities fail to detect any comparative atrophy. The head is rotated a little to the left, and is slightly flexed; she can, however, rotate beyond the median line, and can hyperextend the head beyond the vertical. These movements are not at all painful, and the small degree of limitation seems due to infiltration in the cervical muscles, especially the trapezii, which appear to be enlarged. The skin, however, is normal, without extra heat, tenderness, or discoloration. There is no special tenderness at any point, no abnormal bony prominence, no lateral deviation, and the posterior wall of the pharynx feels normal to one's finger.

June 16, 1880.—I saw the case again to-day, and find the same stiffness about the neck as was observed at date of last note. A small point of tumefaction is found over the first and second cervical vertebræ. This, however, is movable and separate from the spinous processes. On the evening of the 11th she became weak in the limbs, tottering as she did on former occasions. Went to bed, and in two days was as well as ever.*

With the exception of a few applications of faradism and the use of the head extension in August, 1878, the patient has had no treatment whatever since April 29th of the same year. The parents never manifested any disposition to have anything done, and our services were not urged upon them. In reviewing the case I find many interesting features.

---

* Sept. 4. 1880. examined her for Pott's disease, and can find no symptoms or sign even. Is perfectly well, save the torticollis.

1st. As an exciting cause, an apparent traumatism in October, 1874, viz., a twisting of the neck between the rounds of a chair.

2d. A long stage of two and one-half years, characterized by cervical pain and tenderness, attacks of torticollis, infiltration of the tissues about the cervical vertebræ, etc.

3d. A stage of paralysis, promptly relieved at first by ergot and iodide of potassium, then a relapse ten days after going from under treatment with complete cervical paraplegia and incomplete paraplegia, lasting at least eighteen months.

4th. A stage of contraction lasting a few months.

5th. A complete recovery from the paralysis.

The case is all the more remarkable as it has passed through the most interesting stages without medical or surgical interference.

CASE II.—*Hereditary neurotic diathesis—A first stage of six months, second stage (of paralysis) of ten months—Complete recovery from paralysis, a very slight degree of torticollis remaining.*

Agnes L——, aged four years, was brought to the out-door department of the hospital November 24, 1878. The maternal grandmother died hemiplegic at the age of forty-nine; grandfather now living and healthy. An uncle, aged twenty-five, has been two years insane, the rest of the family, mother included, are healthy. Several members of the paternal grandmother's family have died of phthisis. Family history otherwise good. This child is one of nine, two dead, one from sequelæ of measles and one from convulsions after scarlatina. The others are healthy.

The patient was in good health during the first six months of life, then had a dozen or more boils, about the size of walnuts, over the scalp. Was very sick at this time for four weeks, made a good recovery, and continued well until March, 1878, when the first symptoms of the disease for which the child now comes under treatment were developed. She fell out of bed about this time, though no contusion could be discovered. The mother is inclined to believe that this fall was the cause of all the subsequent ills. During this month (March) she had a severe cold, accompanied with what was supposed to be an ordinary stiff neck. She had much pain in the neck, and the head inclined to the left side. This deformity progressed until the head rested upon the left shoulder. The patient was under treatment for rheumatism until the beginning of November, the pain meanwhile continuing unabated. This was almost constant, referred always to the neck, and aggravated by efforts to hold the head erect and also by passive movements of the head. The pain was so severe that frequently it became intolerable, and recourse was had to opiates. There was no marked febrile or other constitutional disturbance, the general health continuing remarkably good.

About November 1st she began to lose power very gradually in the left arm, and soon afterward in the right, then in the left leg. All came on gradually, almost imperceptibly. During the last week she has been growing rapidly worse. The case finally came under the care of Dr. Madden, of Brooklyn, and he very kindly referred it to the hospital.

The examination to-day (November 24th) reveals a marked degree of torticollis on left side, the cervical muscles being quite tense; an apparent atrophy of the deltoids, though measurements are the same on both sides; a flabbiness of the muscles of the arm, and no apparent elevation of temperature. The little patient can move the wrist and the fingers feebly, raises the arms slowly from the side, getting them barely high enough to touch the head with the finger. There are responses to both currents, though a very strong faradic current is required to get a response in the deltoids. The bowels move regularly every day. Iodide of potassium, gr. iij., t.i.d., is ordered.

November 26th.—The pulse this morning is 110, respiration, 25, temperature, 97¼°. The inferior extremities are not affected to any marked extent.

November 30th.—A body brace, with a head support, is applied, and efforts to restore the head to the normal position produce great pain. Double the dose of the iodide.

December 2d.—Rests better nights, and is able to feed herself, a thing she has not been able to do for two weeks. Ordered potass. iodid., gr. x., and ergot, fluid extract, ʒ ss., three times a day.

December 18th.—With the apparatus the head is retained quite easily in position. There is no spinal deformity and no tenderness on concussion. The arm muscles appear to be undergoing atrophy, while the power in the superior extremities is in *statu quo.* As the child walks to-day it does not clear the floor well with the left foot, and the gait is certainly unsteady. The reflexes are a little exaggerated and the epileptoid tremor can be easily excited; the electrical reactions are still preserved, though somewhat diminished in the flexors of the wrist. There is incontinence of urine, or rather an inability to hold the water long after the desire is first experienced. The iodide is increased to grs. xv., and the ergot to ʒ j., t.i.d., both of which drugs have been well tolerated by the stomach.

December 28th.—A specimen of urine is examined to-day: specific gravity, 1030; no albumen; a heavy flocculent deposit after standing. The child is not brought over to-day, but her condition is reported as being about the same as when the last observation was made. The weather is so inclement, and it is so difficult for the patient to attend regularly, that the family physician, Dr. Madden, consents to conduct the treatment at home. The ergot is discontinued, the iodide is continued in same doses, and the doctor is advised by letter to employ a light descending current, with rapid interruptions, three or four times a week.

February 26, 1879.—The mother calls, bringing a letter from the doctor, who writes that faradism has been employed twice a week; that the iodide has been continued, in conjunction with cod-liver oil; that the general condition has been good, and that the pain is less.

It is learned from the mother that her home is in a malarial district, and that the child has often had chills and all the signs of malarial poisoning. Quinine in full doses is advised.

June 27, 1879.—The patient is brought over this morning, with a note from Dr. M., who writes that on two separate occasions she has taken quinine for two weeks, gr. xij. per diem, over a drachm of Squibb's fluid extract of ergot three times a day, until she had taken a half-pound; that she is now taking the ergot and the iodide in combination, and that the faradic current is still being employed once or twice a week.

The child cannot stand or walk. The head is deflected to the left and held very carefully; there is no excessive spinal tenderness, no deformity, no pain on concussion, and no pain on movements, if carefully made. As the child lies prone, if either thigh be grasped with one's hand, the most marked epileptiform tremors are produced, both inferior extremities and nates taking part in the movements. These tremors continue until the position is changed. Reflexes at knee are greatly exaggerated, and can be excited at any part of the leg or thigh by sharply striking the muscles. There is very slight voluntary power in the limbs; the feet are held extended in a straight line with the legs.

The right upper extremity possesses nearly normal power; the left arm cannot be raised to a right angle with the body and there is no power to flex the forearm, while the power to extend is very feeble. The faradic responses in all the muscles paralyzed are good. There is no comparative atrophy of the limbs, though the deltoid regions appear symmetrically atrophied. No incontinence or retention of urine now, though the bowels are habitually constipated.

The diagnosis, long since made out, of cervical pachymeningitis is fully confirmed.

July 9th.—I had my friend Dr. E. G. Janeway see the case with me to-day, Dr. Madden being also present. The doctor examined the pharynx very carefully with his finger, and was unable to satisfy himself of the existence of any vertebral caries. His diagnosis was pachymeningitis with secondary cord lesion—a transverse myelitis—either idiopathic or the result of caries, more likely the former, and his prognosis was a fair recovery. He remarked that in his experience children, as a rule, made good recoveries from such affections. The continuation of the ergot and the iodide was advised, also flying blisters to either side of the spinous processes. I was glad to hear him state that he did not approve of electricity in any form except for diagnostic purposes.

September 3d.—The mother calls this morning with the child, who walks in freely and is able to use the hands and arms with perfect ease. She has not worn any head-spring for ten days The only sign now of disease is an ability to extend the head much beyond the vertical. Rotation of the head is perfect. There is no pain or tenderness in cervical region, and no fulness or angular prominence anywhere. No evidence of bone disease either spondylitis or spondylarthrocace. Examination of superior extremities shows scarcely any loss of power, no atrophy, and a firm grasp for each hand.

As she stands erect considerable pressure downward is made upon the shoulders, and no trembling or unsteadiness in the limbs is produced. The reflexes are normal and no epileptiform spasm can be excited. She stoops normally and all the muscles of the inferior extremities feel firm and are well developed. The general health is excellent. The child has been walking for more than a month, and has only an occasional pain in the neck after fatigue.

The counter-irritation was not resorted to, but the ergot and the iodide were used alternately with quinine. Case discharged.

February 2, 1880.—Calls by request to-day. Walks and runs and uses the hands perfectly. Still no evidence of bone disease. Is the picture of health.*

It occurs to me in reviewing this case that a more classical one of cervical pachymeningitis of the hypertrophic form cannot be found.

Case III.—This case, that of a boy æt. 10½ years, has been presented at a meeting of the Neurological Society, as already mentioned, December 2, 1878, under the following heading:

"*Pachymeningitis Cervicalis Hypertrophica, Occurring in a Lad.—Cervical Paraplegia with General Paralysis almost Complete.—Case still under Observation and Progressing Favorably.*" It has not been published in detail, yet a very fair abstract was published in this journal for January 4, 1880, and is as follows:

The patient, a boy æt. 10½ years, was admitted to the Hospital for the Ruptured and Crippled, August 22, 1878. His family history was exceptionally good. He had been considered a delicate child until he was eighteen months old. From that time until one year prior to his admission to the hospital he had enjoyed fair health, and was free from any paralysis or deformity. In August, 1877, he was pushed against a pile of lumber, striking his back in the lower spinal region. It was not a severe injury; he complained very little, and his mother was unable to find any bruise. The immediate effect passed off within twenty-four hours, and nothing was complained of or observed until the January following, when he had a paroxysm of shooting pains in the back. For a period of two weeks the paroxysms were frequent, and were most severe at night. Relief then came, and he seemed perfectly well until the beginning of June, 1878. Without known provocation, he then began to bend his neck forward in walking, and complained of pain post-cervical. In the month of July considerable pain and tenderness, associated with a peculiarity in his walk, were observed, and there was also a moderate degree of skoliosis. There was also a cervico-dorsal prominence, though slight and uniform. There was no angular deformity. When admitted to the hospital in August, the following symptoms were recorded: a stooped position, the head deflected forward more than twenty degrees from the vertical bearing, a moderate dorsal skoliosis, and an unusual degree of care in walking or sitting. There was no angular prominence at any portion of the spinal column, no tenderness on pressure over the spinous processes—though that had been a prominent sign, and no tenderness on concussion.

On percussion over the posterior wall of the pharynx the patient complained of pain, yet no tumefaction or bony irregularity could be discovered in that region. Motion in the upper cervical region was normal, but was limited in the lower cervical and the upper dorsal.

No reliable signs of a spondylitis or of a spondylarthrocace could be detected. The thorax presented some rachitic changes anteriorly. A head-support was applied, and with that the deformity was nearly overcome. Cod-liver oil and a tonic were prescribed.

During the following month he did very well. In the month of October the head showed a great disposition to fall forward; the head-support became irksome; the patient slept poorly considerable of the time, and the pain and tenderness in the cervico-dorsal region increased. He took to his bed; his chin, in the lateral decubitus, rested upon the sternum. He could not be induced to change his position, and, if left undisturbed, made no complaint. He had vomiting, and the tongue was heavily coated. Ergot, iodide of potassium, and vesication were the special medicinal measures employed. On the *first* of November there was a decided improvement; but on the fourth he was again worse, and on the eleventh there was loss of power absolute in the arms, and partial in the forearm and hands, and there was almost entire loss of power in the lower extremities. The reflexes were exaggerated. Anæsthesia on posterior surface of thighs well marked. Pulse, 120; respiration, 20; temperature, 99½° F.

---

* July 21, 1880.—I examined the case to-day very carefully and the cure is found to be complete. All the movements of the head normal. Possibly a little deviation of head to left, though hard to detect it.

November 14th.—Exaggeration ot reflex and abnormality of sensibility remained. The limbs frequently jerked on the slightest provocation, and assistance was required to restore them to the desired position. Urine drawn by catheter. Pulse, 112; respiration, 26; temperature, 100¾° F. No appreciable atrophy had occurred. All the muscles acted well to medium faradic current. The electro-sensibility was perceptibly diminished.

November 17th.—Has moved the right arm since yesterday. As the forearms were in pronation the hands exhibited a typical approximation to the *main-en-griffe* of Charcot and Joffroy.

November 20th.—Urine had specific gravity of 1012, faintly acid, and contained flaky deposits and phosphates. Temperature, 100½° F., the highest yet reached.

November 21st.—Decubitus dorsal, with lower extremities extended, a position he had not been able to assume since his confinement to bed. Was able to raise both arms from his side to a right angle and to extend the forearm completely.

November 25th.—Epileptiform tremors in legs were marked. He could flex the left thigh with considerable force.

November 28th.—Was able to sit up all day, and to use his left arm in feeding himself.

November 29th.—Incontinence of urine and of fæces. Electrical responses as good as they were one week ago.

December 2d.—No incontinence of either urine or fæces during last two days. Pupils for the first time dilated. Fundus of the eye normal. Sensation in the thighs returning.

The notes from that date forward are as follows:

December 4th.—Otalgia left side; reflexes still exaggerated. Has not sat up for a week. Ergot in drachm doses is renewed.

December 6th.—Bowels moving naturally once a day, and he now calls for the bed-pan.

December 8th.—Can raise the right arm from the side since yesterday. No more otalgia since the 4th.

December 15th.—Is slowly improving, though for the past day or two has complained of pain in the eyes, and no adequate cause therefor can be found on ophthalmoscopic examination.

December 24th.—A day or two ago he stood alone and took a few steps with very slight assistance.

December 27th.—While attempting to stand to-day the right limb is contracted at the knee, and is subject to marked tremor, epileptoid in character. Has considerable tenesmus.

From this date to January 9th, no special changes were observed except that one day he was in bed and up the next day walking about the ward with a chair.

January 17, 1880.—Walks very fairly, although the right foot does not clear the floor well. A tonic has been substituted for the ergot and the iodide.

January 23d.—At 7 A.M. is seized with a violent convulsion, epileptiform in character, lasting about five minutes. It is learned that he has voided no urine for twelve hours, and the bladder is found distended. Immediately after this organ has been relieved by a catheter, the patient is seized with a convulsion more violent than the former, briefer, however. His temperature before the convulsion was 99°, and immediately afterward 100°. At 9 A.M. he has a third convulsion. The urine drawn off was ℥ xvi., normal in color, alkaline in reaction, containing no albumen, as tested by heat and nitric acid, and showing nothing microscopically save a few pus and blood corpuscles. The cause of his convulsions seemed to me an overdistended bladder acting upon a highly sensitive nervous system.

January 24th.—With the exception of a soreness of the mouth and tongue from the convulsions of yesterday, he is as well as ever. Thompson's solution of phosphorus with cod-liver oil is ordered.

February 27th.—Has been gaining in power steadily, and now walks without any support, though he is quite lame in the right limb. There is still no evidence of vertebral caries.

He has been complaining for a week or more of dimness of vision with pain on reading, and on ophthalmoscopic examination to-day, I find the fundus abnormally red, vessels indistinct, margin of disk obscure, veins about normal in size, and arteries very small. In the region of the macula are two or three white glistening spots about one line in diameter.

March 2d.—Dr. C. R. Agnew makes an examination confirming the appearances I found on the 27th ult., and interpreting them as an œdematous retina about the disk. The white spots he regards as probable retinal hemorrhages. He makes out, likewise, with the ophthalmoscope, a hypermetropia of $\frac{1}{7}$ in right eye and $\frac{1}{6}$ in left. The diagnosis is neuro-retinitis descendens.

On the day before, Dr. Webster made an examination, finding the same lesions and the same degree of hypermetropia as Dr. Agnew finds to-day. It is thought very remarkable that this eye-lesion should have followed at such a distance the meningeal lesion. Dr. Agnew orders mercurial inunctions.

His eye symptoms slowly disappeared, and from April 30th to the present time his old lateral curvature has been treated by Dr. Ap. M. Vance of our hospital staff with the paper-jacket and rubber band.* The curve, which was a *rigid one*, has decreased from 1½ to ¾ of an inch.

November 4th.—A thorough examination is made preparatory to his discharge, and all muscles of the extremities are found to have recovered normal power with the exception of the flexors of the right thigh. These are appreciably atrophied, and thus his awkwardness of gait is readily explained. Drs. Agnew and Webster make an ophthalmoscopic examination and find R. E. V. $\frac{20}{40}$; hypermetropia $\frac{1}{9}$; L. E. V. $\frac{20}{70}$, or $\frac{20}{60}$ with × $\frac{1}{9}$. Bottom of disks can be seen quite distinctly; nerve, on the whole, a little pale in both eyes, and arteries a little small. The neuritis has disappeared.

February 18, 1880.—A stone was found in the urethra, and with considerable difficulty extracted by means of forceps in the hands of Dr. W. T. Bull, at the Chambers Street Hospital. He made a good recovery from this, and continued well up to present writing. The formation of the stone is easily explained when we remember his paralysis of the bladder and the cystitis.†

---

* For description of Dr. Vance's brace, see MEDICAL RECORD, June 21, 1879, p. 595.

† August 28, 1880.—I gave the boy a very thorough examination, and could find no symptoms or signs of bone disease. The pharynx was carefully explored: there was no anchylosis in cervical region; no signs of abscess; no torticollis even. The paralysis of the thigh flexors still exists.

In conclusion, if I have diagnosticated these cases correctly, it will be seen that an absolutely perfect recovery does not take place, and, so far as my reading goes, I believe authorities do not claim this. The results in these cases are very good, and enable one to make a good prognosis. In all three the diagnosis of Pott's disease was made and insisted upon by several competent surgeons. The remarks I made on the diagnosis in my first paper apply here, and I shall modify a little the second paragraph of the following quotation. There is such a disease as a non-deforming caries of the vertebræ. I have specimens removed post-mortem; yet in these there is some anchylosis, some welding together, or fusion as it were. I can conceive of a point of bone disease in the inner tables of the vertebræ exciting disease of the dura, yet I know of no cases demonstrated by post-mortem, and theories here are unsatisfactory.

I close this article by quoting from the number of this journal, from which a quotation has already been made:

1. Was it a spondylitis? The absence of any exostotic growths, either on the bodies of the vertebræ anteriorly, or on the processes, the history of the disease, and the kind of paralysis, in my opinion, excluded spondylitis.

2. Was it a spondylarthrocace, or Pott's disease of the spine? The history of a fall without evidence of external violence would suggest very forcibly vertebral disease. Still, within twenty-four hours all tenderness and immediate effects of the fall had subsided, and he was perfectly well and free from deformity for *three months.* The fall was charitably considered as an improbable factor in the etiology of the disease present. It was to be remembered that the first real signs of the disease began in January, 1878, when colds were very prevalent, and, in the absence of any known exciting cause, it was assumed on circumstantial evidence that he contracted a cold, and that the effects of the cold were confined to the cervical spine. The shooting pains about the head and neck were paroxysmal and severe; they lasted about two weeks, and the patient was relieved. Then for five months he seemed perfectly well. Vertebral caries does not act in that manner.

Again, when the torticollis appeared, the deflection of the head was forward, and not backward, as was the rule in torticollis from vertebral disease. Since he had been under our own observation, over three months, tenderness on pressure over the spinous processes had been nearly continuous. As a *rule,* to which there were but few exceptions, that sign was not present in spinal caries. Furthermore, extension and support of the head were intolerable. On those grounds Pott's disease was excluded.

3. Was it a case of pachymeningitis cervicalis hypertrophica? From the symptomatology as described by Charcot and Joffroy, from the exclusion of the two diseases mentioned, and from the kind of paralysis—that which belonged to spinal compression, the diagnosis was reached.

* * *

An Epidemic of Dengue is reported to exist at Charleston, S. C. There are said to be some cases of the disease at New Orleans.

The Summer Home of the Children's Aid Society, at Bath, has been closed for the season. A total of 347 children have enjoyed its benefits for periods varying from a day to a week, during the past summer.

A CASE OF HYDATIDS OF THE BLADDER,

With Report of Autopsy.

By F. C. AINSWORTH, M.D.,

ASSISTANT SURGEON, U. S. A.

The notes of the following case were taken several years ago, and were not at the time intended for publication; but as the literature of echinococcous disease, so far as I have had access to it, furnishes no similar account, and as the case presents several points of interest other than its singularity, the following record may be deemed worthy of publication.

A correct diagnosis of the disease was, of course, never made during the short time the patient was under observation, for he presented no symptoms which hinted at hydatids, either of the bladder or any other organ. No shreds of membrane had ever been voided per urethram. The most careful examination of the urine failed to reveal scolices, hooklets, or any abnormal ingredient other than those pertaining to chronic cystitis. An aspiratory puncture of the tumor in the rectum was determined upon, and might have revealed something; but a general peritonitis, which eventually proved fatal, arising, put all such exploration out of the question.

Max Sterns, musician, band 21st Infantry, native of Poland, age unknown, but thought to be about forty, was admitted into the Post Hospital, Fort Vancouver, in the latter part of August, 1875, complaining of retention of urine. The following history was elicited from him:

Had been perfectly well up to three years ago, when on an occasion he was forced to retain his urine for several hours, in spite of a pressing desire to void it, and when an opportunity to relieve himself came, he was unable to do so for some time, but at last succeeded, though painfully and with great effort, by pressing on the right side of the abdomen. The next day he urinated without difficulty, and had no further trouble until about six months afterward, when, under similar circumstances, he found himself in a like predicament; but on this occasion, failing to empty the bladder himself, he applied to a doctor, who passed a catheter on him without difficulty, and relieved him. From this time the attacks of retention became more frequent, occurring every three or four weeks. Sometimes he could start the stream himself by pressing, as above stated, on the right side of the abdomen, but more frequently was obliged to visit a doctor. In the intervals between the attacks the urine flowed readily and in a full-sized stream. This state of things continued for about a year, during which time the catheter was used on him by several surgeons, both civil and military, and always passed easily and without pain; but at last an attempt to pass a solid instrument during one of the attacks was attended with difficulty. The doctor, however, persisted, and after about an hour succeeded, but only by using a great deal of force, and causing him intense pain. Profuse urethral hemorrhage followed, and continued for three days. Since that time his stream of urine has steadily diminished in size, until now it is very small, and five or ten minutes are required for him to empty his bladder. He can never micturate without pressing on the right side of the abdomen. Complains of a constant pain, referred to the suprapubic and perineal region, partially relieved by evacuation of the bladder, aggravated by retention of urine for three or four hours, and rendered unendurable in six or seven. He also suffers excruciating pain in the rectum during defecation, and says that at all times he has a sensation as of a foreign body filling up the lower bowel. Denies ever having had gonorrhœa or any other disease except those incident to childhood.

On exploring the urethra, a stricture was found at about the bulbo-membranous juncture, which would admit nothing larger than a No. 4 soft instrument. A flexible catheter of this size was passed, and about a pint of urine drawn. Morphia was administered hypodermically, and the patient put to bed. The following day, after a warm bath and another hypodermic, a more careful examination was made, with the following result:

Over the whole of the lower portion of the abdomen pressure caused considerable pain. For about three inches above the pubis perfect flatness on percussion existed, although the bladder had just been emptied. Palpation in that region gave the patient so much pain that I was forced to desist. Gentle pressure revealed nothing abnormal. Introducing the finger into the rectum I found that passage apparently entirely blocked up by a tumor, situated in the region of the prostate. Its boundaries could not be ascertained, for the finger could not be passed around it in any direction. It was perfectly smooth and hard to the touch, and no sense of fluctuation could be detected in it. Pressing it caused pain similar to that felt during defecation. Prolonged but gentle attempts were made with all the instruments at my command to enter the bladder, but nothing would pass larger than a No. 4 elastic catheter, introduced with the stylet, which was slightly withdrawn as the tip of the catheter reached the obstruction, just the manœuvre which is so commonly resorted to in cases of enlarged prostate, and the only one in this instance which was successful. No solid instrument could be passed, and consequently no exploration of the bladder could be made. On the fourth day after his admission to the hospital symptoms of acute general peritonitis showed themselves. This complication proved fatal, the patient dying on September 12th.

The autopsy was made September 12, 1875, seven hours after death. Rigor mortis well marked. Body not much emaciated. The integument in the hypochondriac and epigastric regions was covered with numerous cicatrices, the result of repeated wet cuppings during some previous illness, no history of which had been obtained from him during his treatment in hospital. On opening the abdominal cavity, a small amount of straw-colored serum escaped. The intestines were covered here and there with patches of recent lymph, flakes of which were floating in the fluid which partially filled the cavity. The peritoneum was inflamed throughout its whole extent, but the roughening of its surface, dilation and rupture of subserous capillaries, exudation of lymph, and other changes characteristic of this morbid process, were far more marked in the inferior than in the superior abdominal region. The bladder was distended, reaching about two inches above the symphisis, thickly covered with fresh lymph, and firmly bound down on all sides by old adhesions. The inflammatory process had been more extensive and evidently of longer duration on the right side of the organ than the left, for the pelvic cellular tissue was involved to a greater degree in the former situation than in the latter, infiltrated and swollen, so as to displace the bladder somewhat to the left. The central portion of the mass was disintegrated and purulent, two or three ounces of thick pus escaping as the adhesions were broken up for the purpose of removing the bladder. The bladder, when grasped with the hand *in situ*, had the feel of a hard, solid, immovable tumor. When opened it was found to be completely filled with cysts, about sixty in number, varying in size from a pin's head to a large orange. None of them were attached to the walls of the organ, but were lying free in its cavity. The cysts themselves were all single, that is, none of the smaller were contained within the larger, and consisted of a firm, transparent, colorless membrane, containing a clear, yellowish watery fluid. In addition, there were found two ruptured sacs, evidently the collapsed mother-bladders of the colony, much larger and thicker than the unruptured vesicles, grayish white in color, translucent, and of a gelatinous consistency. Their external surfaces were perfectly smooth, bearing no evidence at any point of having been attached to the bladder. The bladder-walls were very much thickened, and had a hard, inelastic, leathery feel. At the fundus the tissue was so much indurated as to cut like cartilage.

In this locality the normal elements of the middle coat were hardly discernible, their place being occupied by a dense fibrous layer. In the body and neck the muscular layer was greatly hypertrophied. The mucous membrane was thickened, raised into prominent folds, and covered with slimy, muco-purulent matter. No ulcerated points were discovered. The bas-fond was deeply excavated, forming a dilatation, the floor of which was much below the level of the vesical outlet and encroached upon the rectum beneath and the urethra anteriorly.

The urethra was healthy down to the bulbo-membranous junction. At this point a stricture existed, which would, however, admit a No. 8 sound without difficulty after the bladder had been emptied of its contents. The prostate and rectum were normal. The middle lobe of the right lung contained, embedded in its anterior portion, a tumor a little larger than a walnut, consisting of a firm fibrous capsule of a yellowish white color, intimately connected on all sides with the lung-tissue, and containing several cysts, varying in size from a pea to a marble. In appearance they were precisely like the smaller cysts found in the bladder. The lower lobe of the lung was healthy. The upper lobe contained at its apex a few cheesy and calcareous nodules and miliary tubercles scattered more or less throughout it. Right lung sound. Heart and great vessels normal. The lower extremity of the spleen was the seat of a growth about the size of a small orange, similar in its external appearance to the one found in the lung. Like it, it consisted of a firm fibrous capsule embedded in the substance of the organ. Its contents, however, consisted of a caseous matter very much like marrow in color and consistence, and a single large collapsed cyst, folded up and compressed within the cheesy mass. The cavity of the cyst was empty. In size it was about equal, when unfolded, to one of the large ruptured mother-bladders of the colony found in the bladder. Its wall was a little thicker than the above, harder, colorless, and perfectly transparent, resembling exactly the tissue of the cornea. The liver was perfectly healthy, the most careful examination failing to reveal any unnatural appearance. The stomach, intestines, and left kidney were sound; the right was somewhat congested. Right ureter, slightly dilated; left, normal. No enlargement of the glandular apparatus of the thorax, abdomen, or pelvis. The brain was not examined.

Whipple Barracks, A. T., June 21, 1880.

Progress of Medical Science.

On Duboisia in the Treatment of Exophthalmic Goitre.—Mr. Dujardin-Beaumetz has employed duboisia in place of atropia in hypodermic injections in the treatment of exophthalmic goitre. In the two cases in which he has tried it, he has obtained a marked diminution of the palpitations and the vascular pulsations—that is to say, a decided amelioration. This, moreover, is the only result that has yet been secured by any of the methods of treatment recommended for this affection. The effects of the injections were decidedly cumulative, although the doses used were very small—from a quarter to a half a milligramme; distinct symptoms of poisoning, analogous to those produced by atropine, were observed after a few days. Hence, it was found necessary to intermit the injections for several days after every week of treatment, and after a time to discontinue them altogether. The solution used was one centigramme of the neutral sulphate of duboisia to twenty grammes of aqua laurocerasi.—*Le Courrier médical*, July 24, 1880.

Infantile Constipation.—At a clinical lecture held at the College of Physicians and Surgeons, New York, Prof. Jacobi called attention to a form of infantile constipation not mentioned in the books. In this affection the color of the fæces is about normal, but they are deficient in moisture. They are dry and somewhat friable. The passages of young babies are never normally like this. There is evidently here a lack of moisture which may possibly arise from an insufficient secretion on the part of the intestinal glands. It may, however, arise from other causes, one of which is a peculiar anatomical condition occasionally existing in the bowels of the new-born or young infants. A few anatomists have recognized that the intestinal tract is different in the young from what it is in the old. The colon is very much larger and longer, in proportion, in the child than in the adult, and this peculiar condition often remains up to the age of five or six years. The child may have two or even three sigmoid flexures, or the real sigmoid flexure may not be found on the left side, but on the right. In the passages of the young, where the peristaltic action of the bowel is normal and the colon of the usual proportion, the fæces will not be dried out; but where the flexure is long, or there are two or three of them, the fæces will dry out. In the fœtus and the new-born the secretions of the intestines are very copious. There is a great deal of mucus and epithelium, which may become very dry and compressed—to such an amount, indeed, as to constitute actual obstruction. Dr. Jacobi stated that he has met with a number of cases in children, that could not be explained in any other way than by the supposition that there were two or three sigmoid flexures, one on top of the other, and impeding the free passage of the fæces. In the treatment of a case where such a state of things is suspected, the diet must be regulated so that there may be an abundance of water in the food. In the choice of food, oatmeal is to be given in preference to tapioca, rice, or even barley. Purgatives ought not to be given except in urgent cases. Injections are very useful, and cannot be dispensed with. Another cause of constipation like this may be that there is an insufficient physiological action of the muscular layer of the intestine. This may occur in feeble children. In another class of children this constipation does not appear until from six months to one year after birth, and then, from being perfectly regular, they become obstinately constipated. In this class the muscles of voluntary motion, as well as those of the intestine, become diminished in power; they are rachitic children.—*Med. and Surg. Reporter*, July 10, 1880.

Dermoid Tumors of the Cornea.—Dr. John B. Roberts read a paper on dermoid tumors of the cornea, before the Philadelphia County Medical Society, June 9, 1880, and presented specimens taken from a young bullock. The pathology of such growths is the same in the human subject. Each cornea was partially covered by a circular, somewhat elevated growth, closely studded with reddish hairs, such as were seen upon the surface of the animal. In one eye the tumor involved the sclerotic region, and then invaded about one-third of the cornea, while in the other eye the growth seemed to be limited almost exclusively to the corneal tissue, leaving about one-fourth of its surface free from involvement. The tumors were about the size of a ten cent piece, and in one the continuity of the conjunctiva of the sclerotic with the surface of the tumor was easily seen. Dermoid tumors of the cornea in man are usually congenital, and are more prone to extend from the conjunctiva and sclerotic to the surface of the cornea than to be limited to the cornea itself. These tumors are seldom rapid in growth, are non-malignant, and may remain almost the same for years. The treatment of these cases in the human subject depends on the extent of cornea involved. If superficial, the growth may be pared off, as in pterygium. The cornea is frequently, however, involved to a considerable depth, and the anterior chamber may be opened in the attempt. In such cases, moreover, operation will be of little value, even if there remain sufficient corneal tissue to prevent perforation, because corneal opacity will remain at the cicatrix.—*Phila. Medical Times* July 31, 1880.

Case of Nerve-splitting.—Surgeon-Major K. McLeod reports a case of nerve-splitting in *Brain*, April, 1880. The patient had wasting of the left forearm and hand, from which he had suffered for eight years. The little finger and ulnar side of the left hand gradually grew numb, the muscles of the hand wasted, and the fingers became permanently bent. Upon examination it was discovered that the ulnar nerve had undergone thickening. An abscess subsequently formed above the elbow, on the inner side, which discharged spontaneously, and left a sinus which finally closed. Four years afterward the sinus reopened, without, apparently, any fresh accession of inflammation. At this time the ulnar nerve was found to be very much thickened behind and above the elbow, to the extent of about five inches, hard and cartilaginous to the feel, as thick as the middle finger, and painful on manipulation. There was an orifice of a sinus over the course of the nerve, situated about four inches above the inner condyle of the humerus. Operation: a director was passed into the sinus, and it was found that it passed into the interior of the nerve, as far as the level of the inner condyle. After slitting up the sinus, a long linear incision was made which resulted in exposing the nerve for a space of four inches. It was hollowed out by an abscess, of which its thickened texture constituted the wall. This cavity was filled with curdy material. The cavity was thoroughly emptied, and the nerve was split in two from before backward. The continuation of the nerve behind the condyle was somewhat thickened, and contained a few cells full of yellow curdy material. The condition for which the operation was resorted to is a very rare one.

Poisoning by Oil of Chenopodium. — In the *American Journal of Otology*, July, 1880, Dr. Alfred North, of Waterbury, Ct., reports two cases of poisoning by the oil of wormseed. They are interesting on account of the rarity of recorded instances of poisoning by this drug, of the peculiar interest which attaches to the symptoms referable to the auditory apparatus, and of the valuable lesson of caution taught by them with regard to the use of this familiar drug, which seems to possess toxic properties with which it is not commonly credited. Patient, male, æt. 12; was treated by a physician for intestinal worms, and ordered to take a "large overflowing teaspoonful" of the following mixture: ℞. Ol. chenopodii, ʒ j.; ol. terebinth., ʒ j.; ext. spigelii, ʒ iij. M. Sig. dose, ʒ j. Three other children in the same family received smaller doses of this same mixture. The next morning the patient was found breathing heavily, and was with some difficulty aroused. There seemed to be partial loss of co-ordination, his gait was unsteady, and he complained of severe frontal headache and of loud ringing in the ears. Deafness was very marked. Vision normal. He appeared less intelligent than usual. Four days after taking the medicine all the symptoms became aggravated, and the patient remained in bed. Dr. North was then called in, and found the patient entirely unconscious, and learned that he had slept heavily all day. Temperature, 100° F.; pulse, 58, weak and compressible; respiration normal, breathing not stertorous; pupils widely dilated, sluggish, responding only faintly to light. Had vomited on taking food during the day. Patient remained for five days in a state of stupor, and had constant hallucinations. Under treatment he had shown slow but steady improvement, all symptoms abating somewhat in severity; tinnitus aurium little less; frontal headache continued.

Case II.—On the same evening the sister of the previous patient, aged ten years, received a "good teaspoonful" of the mixture. The child was awakened toward morning by extreme nausea, followed by profuse vomiting. She also suffered from inability to walk and adjust her clothing, marked deafness, distressing tinnitus aurium, and severe frontal headache. In short, she was afflicted with all the symptoms which characterized Case I. up to the stage of stupor, only in a less degree. She was never compelled to take to her bed, but improved steadily, though slowly, the deafness and headache being very persistent. Two more children, viz., a girl of seven years and a boy of four, also received a dose. The former took a teaspoonful, vomiting shortly afterward, without any additional symptoms, with the exception of slight nausea. It will be noticed that the symptoms resemble somewhat closely those produced by santonin, its therapeutic ally. They differ, however, in the important particular that the eyes were wholly unaffected by the discolored vision uniformly produced by the latter drug, while the hearing, which is unaffected by santonin, was the only sense perceptibly affected by chenopodium. As to the amount taken in these cases, there is also an element of uncertainty. Had the drachm dose been given as ordered, the patient would have received forty minims of the oil, provided the *medicine had been well shaken*, but on standing the spigelia is almost immediately separated from the mixture, and settles to the bottom. In this condition a drachm of the supernatant fluid would give fifty-three minims of chenopodium. Moreover, on measuring the amount left in the bottle, it was found that ʒ vj. had disappeared from the original ʒ xij. mixture. The mother asserted that none was thrown away, and none given to any one else. Therefore ʒ vj. were distributed among the four children. The youngest is said to have received no more than ʒ ss. As no poisoning ensued, this is probably true. This would leave ʒ vss. to be divided among the three remaining children. Of this, to judge from the effect, the eldest must have received the lion's share, probably getting fully a drachm of the pure oil.

The Anæsthetic Effect of Cold upon the Cornea as a Therapeutic Measure.—Dr. Henry S. Oppenheimer read a paper on the above-named subject before the New York Ophthalmological Society, May 10, 1880. From the number of cases recorded (*Medical Journal*, July, 1880), it would seem that the remedy is a valuable one in most of the cases where disease or injury of the cornea is the cause of pain and photophobia, with or without blepharospasm. Twenty-five cases have so far been collected. Of these, four were interstitial, two diffuse (non-interstitial), and ten phlyctenular keratitis. Five were cases of panus, one was inflamed staphyloma, and three were superficial wounds of the cornea from scratching with different substances. The directions usually given were to drop the water, as cold as it could be got from melting ice, into the eye, while the patient himself, or the attendant, held the eye wide open. This was kept up for a few minutes every half-hour or hour. As the eye improved, these intervals were lengthened. An eye-dropper or sponge was used to drop the water from. The mode of action of the cold seems to be probably a double one. The lessening of the photophobia may be due to temporary paralysis of the more superficial plexuses of corneal nerves, while the subsidence of the injection may be accounted for through its astringent effect. It is also possible that the antiseptic effect of cold may have a slight influence. The cold is very badly borne in suppuration of the cornea, as was found in one case experimented on, in which one or more phlyctenulæ had broken down, and thus left an ulcerating surface on the cornea.

Extra Puerperal Mastitis caused by Psora.—Dr. Karst, of Kreuznach, reports a case of mastitis apparently due to the presence of the itch-insect about the mamma. He was called to see a woman with a mammary abscess, which he incised. In renewing the dressing he was told by the patient that for several weeks past she had greatly suffered from intolerable itching all over her body, and that she had attempted to relieve this irksome condition by continual scratching. A careful examination now revealed indications of the presence of scabies and excoriations, the latter especially numerous around the nipple. These excoriations had proved a source of infection, leading to suppuration. A similar case, occurring in the practice of a colleague, is also mentioned.—*Berlin. klin. Woch.*, August 9, 1880.

◆

Hay Fever Sufferers.—At a recent meeting of sufferers from hay fever at Beach Haven, N. J., a resolution was passed "that this congress endorses the opinion expressed at a meeting of the United States Hay Fever Association" that the remedy for the complaint is the ocean.

PRELIMINARY EXAMINATIONS AND THE GENERAL PRACTITIONER.

SEVERAL years ago Sir William Gull testified before a parliamentary committee that there should be such preliminary examinations established as would cut off thirty-three per cent. of the candidates for the medical profession in Great Britain. In reply to a further inquiry he expressed the greatest confidence that a sufficient number of able and intellectual men would still enter the profession, for he believed that as soon as it was raised to a higher intellectual distinction more men would come into it; and the better the men who were selected at the beginning the fewer failures there would be as the examinations proceeded. Through the efforts especially of the General Medical Council and the medical journals some improvement has been made in English medical schools. That a satisfactory condition has not been reached, however, is shown by the fact that, at a recent meeting of the Medical Council, a whole week was spent in debate upon the matter.

When so much attention is paid to such a question in England, where preliminary education at least exists, it may well be worth while to consider it here, where we have hardly its semblance. It is a little startling to learn that two of the medical colleges of New York city, for instance—two of the largest colleges in the country—require no preliminary examinations whatever. The annual catalogues of most of the other colleges reveal a similar state of affairs or announce preliminary requirements unworthy of a reputable boarding-school.

It is becoming the fashion now for medical colleges to advertise themselves by announcing long courses with rigid and frequent examinations. This is a very happy condition of affairs and indicates some progress, but the profession should not be too much impressed by the glitter. Annual announcements can be made to present a very attractive appearance. Alluring rhetoric and beautiful topography, however, do not constitute educational reform. We have before us the elegantly printed statements of requisites for the matriculation examination in a very reputable western college. There are required: (*a*), English composition; (*b*) arithmetic, including decimals and vulgar fractions, and algebra, including simple equations; (*c*) elements of physics. The examination in the above requisites is not called for if the applicant has any literary or scientific degree or a certificate from any high school or academy or medical school. And, finally, if the student fails in the trying ordeal, if he mixes up his tenses or cannot point off his decimals or balance his equations, he can still matriculate, on condition that he make up the deficiency during his first year. It is evident that such a test as this of fitness for a learned profession amounts to very little.

The test is small, even when compared with the English requisites. Thus, the recomendations of the General Medical Council of Great Britain include, besides the three things given above: English history, modern geography, Latin, geometry, some modern language, botany, or elementary chemistry.

We wish then to emphasize these facts, that American medical colleges require, as a rule, no preliminary examinations; that in this respect they are far behind the colleges of other nations; and finally, that preliminary examinations are urgently needed both to sift the candidates for medical degrees and to lighten the work of the matriculated student and his teacher.

The deficiencies and the needs to which we have thus referred are well enough known to educators, and are perhaps trite enough facts to every one. We do not propose to lecture the medical colleges just now upon their sins. It is not these institutions alone that are to blame. There are duties in the matter which belong to the general practitioner as well as to the colleges. It is he who in most cases advises young men in regard to studying medicine. It is in his office that the study begins, and it is he who sends off the student in his various stages of immaturity to the medical schools. General practitioners now have the custom of taking every student into the office who applies, no matter what his mental capacity or educational training. This should not be so. They have a weightier influence than any one else in deciding who shall study medicine. This responsibility should be understood. The barriers to the study and practice of medicine in America are inconceivably slight. All kinds of callow youths—and we may add maidens—can step in. The colleges are doing something to make the medical education what it should be, but their efforts are crippled by competition or altogether paralyzed by selfishness and ambition. It is to the individual members of the medical profession, therefore, that we must look for help. Let country and city practitioners be a little careful of the youths they take into their offices. Let them remember that the good repute and high standing of the profession will be injured by encouraging the half-educated to become physicians. The satisfying of a petty ambition to have office students will counterbalance but poorly the injury which the influx of physicians without education or mental training can accomplish. It may not be necessary that every medical student should be a bachelor of arts ; but it is necessary that he should have a thorough knowledge of certain elementary branches, and that he should know how to study and how to reason. Let the general practitioner see that his pupils have some qualifications of this kind before he sets them at work on the bones.

THE ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION.

The editor of the *British Medical Journal*, commenting upon the recent meeting of the British Medical Association, states that from beginning to end it was an uninterrupted and brilliant success. There were eight hundred members and guests present, "and if it had been possible," says the writer, "to realize by anticipation how important, interesting, and pleasing the occasion would be, the numbers might have been trebled." The *Lancet* takes a less roseate view. Its correspondent writes that on the whole it would not appear that the British Medical Association is a favorable field for the prosecution of any serious study. So long, it says, as there is eloquence, or prettiness, or great novelty, the attendance is good, but apart from these it immediately languishes. As an illustration of this, the Pathological Section on one day had not enough audience to make a quorum ; on the next day the section was packed at the expense of every other, by members anxious to hear Sir James Paget's address. The meeting, the critic continued, though not marked by any scientific work of very unusual moment,'was thoroughly enjoyed by all present.

We present in another column a report of some of the work done by the Association. The addresses delivered were all of a high order; and if we may judge by the comment and attention which these addresses received, they represent very conspicuously the scientific work of the meeting. The Sectional work embraced, besides the papers, several instructive debates, such as that upon antisepticism, the germ-theory, urethrotomy, etc. ; but the attendance at the meetings was not large, nor were the papers very numerous.

Much labor was expended upon the addresses, however. These were, without exception, thoughtful, instructive, and finished efforts, though varying much in originality and practical value. They held the attention of large audiences.

The social enjoyments of the occasion seem to have far outshone those of any previous meeting, A reception, a dinner, an afternoon garden-party, an evening conversazione, which was really a lawn party on a scale of oriental magnificence in the matter of Chinese lanterns ; and finally, various excursions into the surrounding country, made up almost a giddy whirl of amusements.

The conferring by the universities of the honorary degrees of LL.D. upon twelve leading physicians and surgeons is a gratifying event to the whole profession, as well as to those individuals who were thus specially honored.

It would be natural to compare this meeting of the British Medical Association with that which took place in this city last June, and it will have to be confessed that we are very far behind our British brethren in efficiency of organization and careful scientific work, as well as in brilliancy of oratory. We had some papers that could not be surpassed, but we had a deluge of mediocre efforts. There was about our meeting evidence of a vast deal of mental activity, but compared with foreign work it was crude and immature.

UNNECESSARY VIOLATION OF HYGIENIC LAWS.

The city of Providence, albeit possessing a health officer of ability, has seen fit, during the hot weather of August and September, to dredge out its river, which extends directly into the heart of the city, and serves largely as an outlet for the sewers of the adjoining sections. For weeks past the stench in the vicinity has been sickening. It need cause no surprise to find a decided increase in the typo-malarial diseases of the city this fall, resulting from such stupid and wholly unnecessary violation of hygienic laws.

* * *

On the Treatment of Jaundice with Large Doses of Ipecac.—Dr. Henry Cook, of Bombay, writes a suggestive article in *The Practitioner* on the above subject. Jaundice he divides, as usual, into the hepatogenous and hæmatogenous. The more frequent cause of the former variety is, of course, a catarrh of the gall-ducts; but, in addition, there is often a form of hepatogenous jaundice, in India, at least, which comes on gradually, and is probably due to an obstruction or lesion of some kind in the minuter divisions of the hepatic duct. Hæmatogenous jaundice in India is oftenest due to malarial fevers. Now, in jaundice due to any of these three causes, but especially in the second form, he has found large doses of ipecac to act better than anything else. In one case he gave on the first day forty-five grains. Improvement began on the day following. On the third day he gave a dose of thirty grains, and two days later another dose of twenty grains. Improvement was steadily going on. In other cases two doses were sufficient to restore the normal action of the liver. Dr. Cook relates one case of hæmatogenous jaundice due to malarial fever, in which the large doses of ipecac apparently acted well.

Reviews and Notices of Books.

Annual Report for 1879–80, of the Foochow Medical Missionary Hospital, and of the Opium Asylum in Connection with the A. B. C. F. M. Mission, under the Care of Dauphin W. Osgood, M.D.

The previous hospital reports of Dr. Osgood have been full of curiously interesting facts, and the present one forms no exception. Dr. Osgood's hospital is a small one, holding fifty or sixty patients, and most of the medical work is done in the dispensary. Altogether, 7,838 patients were treated during the year, an increase since 1876 of nearly 3,000.

Some comments are made upon the diseases most commonly demanding treatment.

Skin diseases outnumber all others, it is said, and will do so until the Chinese learn cleanliness.

Dyspepsia is exceedingly common, 2,395 cases having been treated. The cause of this is largely the poor food, the rapid manner in which it is eaten, and the use of opium. The food among the laboring classes consists largely of rice or dried potato, and turnip-tops or other greens, fried in oil, with a little dried fish or bean-curd as a relish. Such a diet costs about $1.50 or $2.00 per month. As there is generally a limited quantity, even of this, it is eaten hastily, without proper mastication. Worms (ascaris lumbricöides) are very common—so much so that it is considered wise to administer a vermifuge before any operation.

The Chinese have novel ways of committing suicide, a practice which is quite popular with them. Eating gold foil, and cutting off the tongue, are some of the methods resorted to.

Foot-binding receives a short notice. The shoes worn by some of the women in Foochow are, it is said, only two inches in length. If the Darwinian theory be true, it would seem that the habit of foot-binding, practised in China for more than a thousand years, ought to modify the size of the Chinese foot; but no change seems to be taking place!

Regarding leprosy, Dr. Osgood says he has never seen any cases cured, and very few have been benefited. Dr. Gould, of Swatow, however, who has a leper hospital in his charge, reports some cases cured and many improved. As a rule, the children of lepers are free from the disease. It is believed that a husband cannot give it to his wife, or the wife to the husband. There is a superstition, however, that a female leper can communicate the disease by sexual intercourse to anybody but her husband, and thus get rid of it herself. With this object in view, some of the leprous women lead lives of immorality.

The practice of midwifery is in the hands of old women, who know nothing of the art, and many lives are lost in consequence. A woman, after parturition, is closely confined to her room, doors and windows are closely shut, and care is taken to prevent the access of fresh air. She also avoids bathing for several days, and drinks ginger-tea to prevent catching cold. The result of this line of treatment is frequently puerperal fever.

The practice of surgery consists largely in the use of acupuncture, caustics, and cauteries. They wisely refrain from the use of the knife. Fractures are put up in bark splints, and frequently unite with but little deformity.

Diseases of the eyes are for the most part treated by internal medication. The only attempt at operative procedures ever seen by Dr. Osgood consisted of two pieces of bamboo tied together so as to strangulate a fold of skin, in a case of ectropion.

The medicines of the Chinese are derived from each of the kingdoms. A popular tonic is made of tiger's bones and tendons. Toads, frogs, snakes, wasps, elephants' skin and excrement, all are officinal.

The Chinese criminal code is rather hard on the doctor; if a patient dies as a result of an error in judgment, the doctor is not allowed to practise again. If any departure from the regular rules, with sinister designs, is detected, the doctor's head is chopped off.

The Foochow missionary hospital is interesting from an economic point of view. The hospital with fifty beds, and the dispensary with 7,437 patients, were carried on during the year for the sum of $1,732.19. This is better understood when we see that the wages of attendants are from $20 to $72 a year.

The Report of the Opium Asylum states that 350 cases were treated in the past year. Of these, eight absconded, the rest were discharged, cured of the desire for the drug. It is impossible to state, says Dr. Osgood, with any accuracy, what proportion of Chinese are addicted to opium. It is exceptional for women or children to smoke. Probably half the lower classes in cities use it; among farmers the practice is not so much found. But it is a common saying in China, that the opium-shops outnumber the rice-shops. Dr. Osgood condemns the use of opium unqualifiedly; he considers it an unparalleled curse, and disagrees entirely with the occasional apologists for its use. The Chinese themselves, he says, universally condemn it.

The plan of treatment in the Opium Asylum consists in confining the patient in the building for the first week, and compelling the total abandonment of the drug; in attention to diet, giving food in small quantities frequently, and, when necessary, adding stimulants; the administration of chloral hydrate, gr. xx. q. 1 h. as required, for the first two or three days; bromide of potas., tonics, etc., are also used. The tonic treatment is to be kept up several weeks after leaving the asylum. The desire for opium ceases in a few days, usually by the fifth or sixth; but the patients generally are left with impaired vitality, dyspepsia, or lung disease, as the result of their habit. The average daily amount of opium smoked was about eight to ten grammes.

Malaria.—Annual Address delivered before the Madison County, N. Y., Medical Society, April, 1880. By Dr. J. L. R. Wadsworth.

The point of especial interest in this well-written pamphlet is, that malaria can generally be observed to decrease in proportion as the activity of vegetation increases. Some statistics showing the variation in the amount of malaria in different localities are given.

Questions Submitted to Graduating Classes of the Medical College of Ohio, from 1871–72 to the Present Time.

This is the title of a small pamphlet that will doubtless be useful to students on the eve of examinations.

◆

Dr. Tanner has taken the stump to tell what he knows about fasting. His attitude toward the regular profession would be mildly characterized as hostile.

Reports of Societies.

THE BRITISH MEDICAL ASSOCIATION.

Forty-eighth Annual Meeting.

Held at Cambridge, England, August 10, 11, 12, *and* 13, 1880.

First Day—August 10th—General Session.

The meeting of the Association opened with a larger attendance than ever before. The first address was that of the President, Dr. Humphreys, and it was pronounced the chief event of the session. The first part of it was devoted to showing how little the University of Cambridge had done for medicine in the past, and what promise of work it gave for the future. Cambridge now has unequalled advantages for teaching anatomy, physiology, and chemistry. Good practical instruction in medicine and surgery is also given. It at present has over one hundred medical students. There is every promise that the university will continue to do still more for medicine.

Dr. Humphreys then spoke of the work of

CUMULATIVE OBSERVATION,

which it was the duty of the members of the Association to pursue more vigorously and satisfactorily. "This work," he said, "the work of collective action, the pull-together of eight thousand members of the profession, had been too little attempted, or if attempted, had been productive of too little result. It is, perhaps, the only work in which all, or a large part of the members, can really and fully participate, and to which each can contribute his mite. It is almost the only way in which questions relating to the effect of temperamental, climacteric, and topographical agencies upon disease, and many others, can be fully investigated and solved. To engage members of the Association as participators in any division of such work, would prove one of the most powerful inducements to the cultivation of observation and thought respecting the mass of facts which are passing, now too often unheeded or unnoticed, before their eyes." In order to carry out such a project as this, there would have to be a system adopted. There should be, in the first place, a well-paid secretary or registrar, who would collect, codify, and act with a medical investigation committee. The art of composite photography would be a valuable adjunct whereby typical features of certain conformations, and of the features of temperament and character could be obtained.

At the close of the address it was voted that the Committee of Council be directed to consider how the President's suggestions could be best carried out to a practical result.

Dr. Alfred Carpenter read the annual

REPORT OF THE COUNCIL.

This showed that during the past year the receipts of the Association had been $75,000, and the expenses $60,000. The balance for the year in the treasury is over $10,000. The total membership of the Association at date was 8,052, an increase of about 900 during the year.

The medal of the Association for distinguished services had been given to Dr. William Farr, C.B., F.R.S.

The organization of three new branches in Australia was announced.

During the year the Parliamentary Bills Committee had succeeded in getting a new warrant which greatly improved the condition of the army medical service. It had been trying to do a like work for the navy. The same committee had done much to secure the compulsory vaccination of children, and to introduce the use of calf's lymph.

The Committees on the Habitual Drunkard's Act, on Hospital Out-patient Reform, and on State Medicine, had no special progress to report.

The registration of infectious diseases had been introduced into thirteen towns and cities; it would doubtless be still further extended in the coming year.

The report of the Committee of Council was adopted.

Second Day—August 11th—General Meeting.

Dr. John Buckley Bradbury, M.D., F.R.C.P., delivered the address in medicine, choosing for his subject

MODERN SCIENTIFIC MEDICINE.

Dr. Bradbury made it the object of his address to show what modern medicine now owed to physics and the exact sciences. These were, he said, being introduced more and more into everyday practice, and were slowly but surely tending to take away from medicine the reproach that it was not a science. He gave a brief review of the discoveries and practical uses of the various instruments of precision now employed by specialists and general practitioners. Dr. Bradbury did not make his review a complete one, but referred chiefly to those instruments which he himself employed in his own work.

By the aid of the *microscope*, an advance, he said, had been made in the diagnosis of idiopathic pernicious anæmia. By it Wilks had discovered that there was in this disease no increase in the colorless blood-globules. This fact, combined with others which the microscope had first brought to light, made it possible to differentiate between anæmia, chlorosis, leukæmia, etc. The vast progress in pathology which the microscope had rendered possible was only referred to. The discovery of the disease trichinosis by Zenker, in 1860, with all its subsequent good results in the saving of human life, was due to the microscope. In view of the recent discoveries by Mr. Power of a parasite resembling trichinæ in the voluntary muscles of typhoid fever patients, the possibility that that disease is a form of trichinosis was hinted at.

The *thermometer* had done even more than the microscope to place medicine on a scientific basis. The "Treatise on Medical Thermometry," by Professor Wunderlich, has done more than any other work to further the progress of scientific medicine in the last ten years. Owing to it we are able to diagnosticate diseases which before, at an early stage, were confounded as tuberculosis and typhoid fever. We can make more confident prognoses, and use our drugs with more precision. It has led to the antipyretic treatment of fevers, which Dr. Bradbury endorsed. The special value of local thermometry was described, and M. Peter's investigations into the parietal temperatures in pleurisy were given. These show that we can tell by the thermometer whether the effused fluid is being absorbed or is increasing, and at what rate. The observations of M. Peter in cases of tuberculosis, confirmed by M. Vidal, show that as soon as tubercles occur at any point in the lung, the temperature rises there, and in doubtful cases of phthisis where the physical signs are not developed, local thermometry may assist in arriving at a correct conclusion. M. Peter's investigations in regard to the differences between the local temperatures of the abdominal parietes in ascites and in the various forms of peritonitis were also noticed. The value of temperature observations in localizing lesions of the brain was guardedly endorsed. General thermometry is useful in diagnosing cerebral hemorrhage from alcoholic poisoning; true apoplexy from the apoplectiform seizures of general paresis, disseminated sclerosis, cerebral softening, and uræmic coma.

The *ophthalmoscope* has furnished invaluable means not only of diagnosing diseases of the eye, of helping the recognition of intracranial tumors, syphilis, chronic Bright's disease, acute tuberculosis, tubercular meningitis, cerebral embolism, and locomotor ataxia. Cases of apparent brain disease, but in which the symptoms are really due to anomalies of refraction, recognizable by the microscope, also prove the value of the instrument to general medicine. Illustrations of the use of the instrument in detecting the various diseases above-mentioned were given. The ophthalmoscope, Dr. Bradbury concluded, must no longer be regarded as an instrument of use only to the ophthalmic surgeon.

The *laryngoscope* had not materially extended its field during the last ten years. Dr. Marcet had, however, shown that with it laryngeal phthisis could be very early detected, even before the lungs were affected. The use of the instrument in diagnosing syphilitic laryngitis and in determining the presence, extent, and character of the membrane in diphtheria, was also a recent addition to medicine.

The *sphygmograph* was considered at great length. Dr. Bradbury believed it would prove of great service sometimes in the early diagnosis of Bright's disease. The increase of vascular tension, indicating an arterio-capillary fibrosis, might precede any structural change in the kidneys; and if detected thus early, the threatened Bright's disease might be kept off. The discovery of high arterial tension might be a help in indicating other pathological conditions and in pointing the way to successful treatment. As one of the remedies for high tension, Dr. Bradbury recommended bleeding. He expressed his confidence that bleeding was now a much neglected measure, and that it would be oftener employed in the future. Dr. Bradbury discussed the causation of albuminuria. He also spoke of the way in which Dr. Brunton, through the help of the sphygmograph, discovered the value of nitrite of amyl in angina pectoris.

The use of the *aspirator* was not dwelt upon at any great length. The speaker referred to his success with it in tapping hydatids of the liver.

The *stethometer* was also passed over briefly. It will sometimes indicate traces of lung-disease that no physical examination of other kinds could display. Its chief value is in estimating the probable course of cases of phthisis and pleurisy.

The *spectroscope* is said by Dr. McMunn to enable one to distinguish blood from the bladder or urethra from blood from the kidney; and blood from the stomach from blood from the lungs.

Electricity is an agent that has helped both the diagnosis and treatment of disease. By it we are enabled to distinguish between spinal and cerebral lesions in cases of paralysis, and between peripheral and central nervous lesions.

Metallo- and magneto-therapy were reviewed by the speaker, who regarded the phenomena reported by Charcot and others as deserving more credence than is given by some. The theory of "expectant attention" he did not think sufficient to explain everything regarding the phenomena of transferred sensation.

Third Day—August 12th—General Session.

The members of the Committee of Council for the ensuing year were elected. Mr. Waters read the report of the Medical Reform Committee, which was afterward discussed. The address in Surgery was read by the Chairman of the Section, Mr. Timothy Holmes, M.A., F.R.C.S. Its subject was

FERGUSSON AND CONSERVATIVE SURGERY—EXCISION OF THE KNEE AND HIP.

Mr. Holmes said that British surgery was a thing to be proud of. English surgeons had particularly distinguished themselves in the practical part—that of healing their patients. Almost all the improvements in operative surgery were of English origin. The orator then paid a tribute to Sir Wm. Fergusson as the father of conservative surgery. In lieu of amputation or the slow decay of chronic disease, he had introduced two almost forgotten operations—excision of the hip and excision of the knee.

Mr. Holmes proceeded then to estimate the present position and value of these operations. He spoke in the deepest scorn of statistical methods, believing they had done more harm than good. By numerical statements, he said, it might be proved that "the homœopathist who soothes the sufferings of dyspeptic gluttons or hysterical fine ladies, are better practitioners than the great physicians who are consulted in all serious emergencies."

Mr. Holmes nevertheless introduced some figures showing the prevalence of the practice of excision in some of the great London and provincial hospitals. At Guy's Hospital, the operation for excision of the knee was performed eighty-nine times during the five years ending 1878; and at St. Thomas's sixty-two times during the same period. In the large hospitals where excision is performed, he believed that there was an increasing tendency to use it less as an operation of urgency than as one of expediency, and rather for the purpose of superseding the expectant treatment than as a substitute for amputation. The tables of Mr. Holmes also showed that there has been a reduction in the mortality of the operation from about twenty-four to less than ten per cent. Though very favorable results were secured by doing this operation under Lister, these results were no better than surgeons had obtained who did not employ this method, but were careful to dress the cases themselves and to leave the parts long undisturbed. Mr. Holmes gave as indications for excision: the strumous cases where the bones are superficially ulcerated; cases in which the synovial membrane has degenerated; cases of limited inflammation tending to necrosis; cases of abscess of the bone not extending too far into the joint; and cases of rheumatoid arthritis. Here, if the patient is healthy and especially if a child, the operation may be tried with fair prospect of success.

As a fair summary of the most recent experience the following propositions were laid down:

1. Excision of the knee is one of the indispensable resources of surgery, and is useful in all three classes of cases, viz., in those where, otherwise, amputation would be indicated; in those where the expectant

treatment might succeed, but is dubious; and in cases of vicious anchylosis.

2. As a substitute for amputation, it is indicated in early life, and in non-tuberculous subjects; in cases of limited caries of the bones, of degeneration of synovial membrane, and in some conditions of necrosis of the articular surfaces; possibly also in abscess in the ends of the bones.

3. As a substitute for the expectant treatment, it seems to be justified, and is extensively used in cases where the patient's circumstances and the slow progress of the case, render the surgeon hopeless or very doubtful of recovery with sound anchylosis.

4. It is also frequently used, and very successfully, in cases of vicious or deformed anchylosis.

5. Attempts have been made to limit the place of excision by opening the joint and drainage, and by some other partial methods. These attempts have been fairly successful, especially in cases where the affection is rather of the synovial membrane than of the bones, and they deserve more extensive trial than they seem as yet to have obtained.

6. At the same time, the mortality from excision of the knee seems of late years to have been so greatly diminished as to encourage the hope that the limit of age which it has been found necessary hitherto to observe may be extended, and it may be judged prudent to apply the operation to the treatment of the more chronic affections of later life, such as chronic rheumatic arthritis, more extensively than has been done up to the present time.

In cases of hip disease, Mr. Holmes sums up his views as follows: excision of the hip ought to be very rarely indeed required if the disease be treated properly at its commencement; in cases seen at an advanced stage of the disease, it is chiefly when sequestra exist that the operation is necessary, though it may be advisable as a means of shortening the treatment in other cases also, when the patient cannot obtain the prolonged surgical care essential to natural recovery.

The speaker in conclusion showed the evils to the poorer class of the present out-patient hospital system, in that it rendered the treatment of chronic diseases so unsatisfactory. He referred to the scheme now under consideration of establishing provident dispensaries throughout the metropolis of London.

At the close of the address a resolution of thanks was moved by Sir Henry Thompson, who made a brief and eloquent speech.

The report of the Scientific Grants Committee was then made. [A summary of this has appeared in the RECORD.]

The members of the Joint Committee on State Medicine were re-elected for another year.

The ceremony of the presentation of the Gold Medal of the Association to Dr. Farr then took place.

FOURTH DAY—AUGUST 13TH—GENERAL MEETING.

The meeting opened with the address in physiology by MICHAEL FOSTER, M.D., F.R.S., on the

RELATIONS OF PHYSIOLOGY AND PATHOLOGY—THE PROFESSIONAL ASPECT OF PHYSIOLOGY.

Physiology might be defined, he said, as the actions and reactions of living beings; differing, therefore, from morphology, which treats of the characteristics of form. These two branches of science were converging, and would, in times far distant, unite; that is to say, we shall then know function by studying structure, and we shall know what is the structure of a living being when we know its function. Dr. Foster showed that the physiological inquiry now goes deeper than the investigation of function simply; it studies the molecular changes of the living cells, the ultimate vital phenomena. This was a fact which proved that physiology is closely related to pathology, that the two sciences are in fact one, and can no more justly be separated than can the science ot meteorology be divided into a science of good weather and a science of bad. The speaker lamented the neglected condition of pathological study in England. There is only one solitary institute in that country devoted to pathological inquiry, and that one exists under difficulties, and occupies only part of the time of a largely engaged practising physician. A new chair of pathology, very fully equipped, is, however, being erected at Cambridge.

Pathology, the lecturer thought, was not only the rational basis of the healing art, but also an important intellectual equipment for every practitioner who is not simply a machine for prescribing drugs in a dull, mechanical manner. But the salutary use of pathological doctrines requires a certain critical power, and the building up of this power is one of the chief functions, especially for the active practitioner, of physiological study. Physiology might be considered the watch-dog against vagrant pathological theories. The study of physiology was not only practically useful, but it disciplined the mind to habits of careful reasoning and close observation. This was the case at least in schools where the science is taught as it should be. It was to be regretted that in so many of the metropolitan medical schools physiology was taught by those who gave themselves but partly to the study, most of their time being devoted to a medical or surgical practice.

Dr. Foster compared the two studies, anatomy and physiology. The former was, he believed, most useful as a means of mental discipline, its practical value was small apart from this. In former times it had been advisable to insist rigorously upon this study to the exclusion of physiology. Now, he thought, equal discipline could be obtained from the study of physiology, and, in addition, it would train the mind to better habits and fill it with more useful facts. He would have anatomy hereafter made secondary to physiology.

Following Dr. Foster's address were a number of reports of special committees. That of the Committee on Out-patient Reform was made by its chairman, MR. TIMOTHY HOLMES. He said that the work of the committee was now at a stand-still, because it was divided against itself. He believed that nothing could be done to reform out-patient department abuses until some system took its place. The only possible system was that of provident dispensaries. They were now trying to secure the co-operation of the friendly societies so as to make such dispensaries possible.

Votes of thanks were given to the various officers and local authorities.

Of the events outside the general and sectional meetings, one of the most notable was the

CONFERRING OF THE HONORARY DEGREES

upon a large number of eminent physicians and surgeons. The ceremony took place in the Senate House. All the doctors, actual and designate, marched in, wearing scarlet hoods. The undergraduates' gallery was filled with students who made the usual demonstrations. The public orator delivered the degrees to the twelve candidates, accompanying each with a brief speech in Latin. Sir Wm. Jenner was introduced as celebrated for his great knowledge and success in the treatment of fever, "quæ pulsat pede æquo pauperum tabernas regumque terras." Referring to Dr. S. D. Gross, he said: "Transfluctus Atlanticos, trans oceanum non jam ut antea 'dissociabilem,' patriæ nostræ ad portus nuper advectus est vir venerabilis quem inter fratres nostros transatlanticos scientiæ chirurgicæ quasi alterum Nestorem nominare ausim." When Sir Wm. Gull's name was mentioned, there was a storm of hoots and hisses from the students which stopped the orator's remarks for some time.

THE SECTION OF SURGERY.

The Section of Surgery was opened with an address by its President, Mr. Wm. S. Savory, F.R.S. It was characterized as "clear, eloquent, and useful rather in calling attention to points already known, but apt to be overlooked, than in recording anything new." The subject was

CONSTITUTIONAL DISTURBANCE.

The term "constitutional disturbance" was, the speaker thought, a good one in its application to the effect of local disease or injury. Such disturbance, it was now known, might be brought about by different agencies; chief among them being the nervous system and the blood. The object of the lecturer was to show that two forms of constitutional disturbance from these two causes existed, and that it was very important to distinguish each of them. Mr. Savory then discussed at some length the physiology of the correlation or "sympathy" between different parts and organs of the body. He showed the delicacy and universality of these sympathies, and the distinction between them and reflex action. Continuing, he said, "But impressive as the evidence is of this mutual dependence of parts through the nervous system, it is, nevertheless, clear, that this is not the only agent of sympathy; there is another even more universal, and perhaps more subtle, if in health, more obscure in its operation—the blood. The blood is thus the medium of communication between all parts by virtue of the incessant changes which go on everywhere between the blood and tissues in nutrition. You remember the aphorism: 'Each single part of the body, in respect of its nutrition, stands to the whole body in the relation of a secreted substance,' and Paget's brilliant use of it. And it is not hard to understand that if any part fails to withdraw from the blood, or supply to the blood its proper materials, the blood will be affected, and through it remote parts or organs of the body. The blood may be affected by the introduction of poisons from without, as in cases of wounds, or of morbid changes deep in the tissues; but it may also be affected by local morbid actions and by various forms of perverted nutrition." And the lecturer asserted that between the cases of fever induced by the latter agency, and those induced by blood-poisoning with matter derived from without, it was not possible to draw the line. He believed that the cases of constitutional disturbance due to blood-poisoning were much more frequent than was generally supposed. The poison often worked itself off without producing many symptoms. It might indeed be that some one of the excretory organs was capable of ridding the organism of the poison at once. An illustration of one of the transient forms of

INFECTION OF THE BLOOD,

and the rapid recovery from it by elimination, is that which occurs in the dissecting-room. Persons often experience a nausea or faintness, or notice a taste and smell which indicate the penetration into the system of volatile matter, the result of decomposition. This passes speedily away and is forgotten until some hours after, when the peculiar odor is again recognized in the perspiration, the excrement, or the breath.

The speaker would not give undue weight to the part that blood-poisoning plays in producing constitutional disturbance. The nervous system has its share. Thus the fever which results when the products of inflammation are bound down tightly by fascia, as in whitlow, or in abscess confined by bone, or in disease of a joint, must be provoked through the nervous system. The clinical features of the two forms of constitutional disturbance can be in most cases distinguished. In both there is usually pyrexia, with the rapid circulation and respiration, and the disorders of secretion usually accompanying fever. These signs were, as a rule, common to the two forms of mischief. But beyond these, in the more active forms of blood-poisoning, there are added rigors, sudden changes of temperature, profuse perspiration, etc. Often the distinction between these two forms of constitutional disturbance could not be made out in actual practice, because the two agencies, the nervous system and the blood, were both at work.

Following the address of the Chairman was a long and valuable discussion upon the "Treatment of Wounds." In this Mr. Lister took a large part. A discussion upon internal urethrotomy was opened by Sir Henry Thompson.

[An account of this will appear later in the Record.]

The address in the

SECTION OF OBSTETRIC MEDICINE

was delivered by W. S. Playfair, M.D., F.R.C.P., the subject being "The Teaching of Obstetric Medicine." The speaker described the deficiencies in obstetric medicine of the English schools. This branch of medicine, he said, though of so high importance, was made of but secondary importance in the regular lecture courses. The practical instruction was very small in amount, and the didactic lectures lasted only three months, or were relegated to the summer course. There had been many attempts to secure reform, but so far without success. Dr. Playfair thought that the General Medical Council ought to have among its members some physician who made a specialty of obstetrics and diseases of women.

Dr. Lombe Atthill introduced a discussion upon

UTERINE HÆMOSTATICS,

with special reference to the hemorrhages occurring in the non-puerperal uterus. A large number of gentlemen took part in the debate, and the value of nearly every uterine hæmostatic was discussed more or less. Most of the speakers testified to the value of Chian turpentine in arresting hemorrhage and lessening pain, but it was thought oil of turpentine might act nearly as well. Hot water, ergotine (preferably injected into the gluteal muscles), injections of iron, plugging the cervical canal, pressure on the aorta, external and internal manipulation with the hands (in post-partum hemorrhage), the use of quinine, strychnine, and iron, as adjuvants, were all endorsed.

HEMORRHAGE AND SICKNESS DURING PREGNANCY

was the title of a paper by Dr. Henry Bennett. The speaker took the ground that chronic inflammation of the body of the uterus or of the cervix, very often existed in parturient women, and gave rise to many bad symptoms and accidents, such as laborious gestation, abortion, obstinate sickness, hemorrhage, etc. Dr. Bennett believed in treating these conditions, ulcerations of the neck, inflammations, etc., by surgical interference.

In the discussion Dr. Byrne, of Dublin, said that he did not believe in Dr. Bennett's views. He had seen very few cases of ulceration indeed.

Dr. Grailly-Hewitt said that high authorities had stated that "inflammation" was a word which should be removed from uterine pathology.

A discussion on the treatment of uterine flexions was led off by Dr. Henry Gervis, and participated in by Drs. Herman Bantock, Pallen, Sims, and others. A paper was then read by Dr. Montrose A. Pallen, of New York, on the

ETIOLOGY AND TREATMENT OF LACERATIONS OF THE CERVIX UTERI.

The paper, which strongly advocated the sewing up of all lacerations, and which pronounced lacerations to be of frequent occurrence, was evidently a novelty to the gynecologists present. It was discussed cautiously by several of the gentlemen. None, except Dr. Hewitt, seemed to have ever seen many lacerations.

Mr. T. Spencer Wells opened a discussion on

THE REMOVAL OF UTERINE TUMORS BY ABDOMINAL SECTION.

He said that his whole experience in this operation included sixty cases: thirty-four of removal, with eighteen deaths and sixteen recoveries; twenty-six of incomplete operation, with one death. The mortality had been very much smaller since the introduction of antiseptic precautions. In describing the operation he referred to the importance of sewing up the uterine wound. When this was done, with antiseptic precautions, he thought the intraperitoneal method the better.

The discussion that followed was shared in by Mr. Knowsley Thornton, Mr. Lawson Tait, Dr. J. Marion Sims, Prof. Macleod, and others.

The address in the

SECTION OF PSYCHOLOGY

was delivered by J. Crichton Browne, M D., LL.D., F.R.S.E., upon "Circles of Mental Disorder—Modern Nervous Diseases." The speaker began by deprecating the introduction of the subject of mental diseases into undergraduate education. He thought the curriculum already overburdened, and that the teachings of psychological medicine were now too ambiguous and unsystematic to be useful either in the matter of instruction or discipline. The student of medical psychology should first be broadly grounded on the principles of general medicine.

The speaker then described the three divisions of mental disorders, which he made and which he represented by concentric circles. In the central circle were to be included all the insane and idiotic recognized as such. In Great Britian and Ireland, on January 1, 1880, there were 93,624 of these. Outside of this lies a second one which he would call the "crazy circle." In this we have those whose mental disease is only incipient or slight, such the as inoffensive lunatics, the host of eccentric, half-mad, crack-brained, and imbecile persons who move in every grade of society. Dr. Browne estimated that there were 180,000 occupants of the "crazy circle" in the United Kingdom. Finally, beyond the crazy circle lies another and outer circle, which might be called the neurotic. It embraced all the sufferers from nervous diseases that are not necessarily accompanied by mental disorder. No attempt was made to get a census of this class, but as 70,000 deaths are attributed annually to nervous diseases in England and Wales, it shows that the number of the neurotic circle is large.

The occupants of the

THREE CIRCLES

were constantly shifting from the inner to the outer, or the reverse; sometimes slowly, sometimes rapidly. Neither the population nor the boundary limits of the circles were permanent and distinctly defined. The numbers, however of each are increasing. Dr. Browne gave his reasons briefly for believing that the number of the insane is increasing disproportionately to the population. He spent more time, however, in demonstrating the same thing for the circle of neurotics. He referred to Dr. Beard's conclusions regarding American nervousness, and thought that the same changes were taking place in England, though less noticeably than in America. His reasons for this belief in the increase of neurotic diseases were:

1. The fact that the English are a thinner people than they used to be. 2. That the death-rate from nervous diseases had not diminished, though many cases formerly classed under nervous diseases in mortality reports are not so assigned now, and though some nervous diseases tend to prolong rather than shorten life. 3. That certain diseases in which the nervous system plays a prominent part are on the increase, *e.g.*, diabetes, granular kidney, heart disease, aneurism, rheumatism, and gout. 4. Other points adduced were the increased frequency of premature baldness, decay of the teeth, the necessity which annual holidays have become, the rise of hospitals for nervous diseases, the rapid growth of neurological science, and the increased consumption of neurotic remedies.

The causes of this increase could be summed up under, 1st. The increasing complexity of the nervous system. 2d. The increasing complexity of life. Of the many conditions of modern life tending to promote the increase of mental and nervous diseases, Dr. Browne spoke especially of education, which, as now conducted, is full of danger to the young. The structural complexity of the brain was not reached at once nor at a single period of time. Different parts became perfected and capable of functioning at different times. The various powers of the mind ought to be cultivated then at the time that their structural basis was becoming developed. Certain mental capacities originally good might become utterly lost by lack of training. The speaker believed that muscular exercise, and especially manual dexterity, might help to develop mental qualities.

At the close of the President's address a discussion

ON THE INFLUENCE OF ALCOHOL IN THE CAUSATION OF INSANITY

was opened by Dr. G. W. Bacon, who was followed by Drs. H. Sutherland, Hack Tuke, and others.

The general opinion seemed to be that the statistics on the point, so far given, greatly exaggerated the importance of intemperance as a cause of insanity. It was often only an early symptom of the mental disease. Further and more exact data seemed to be needed. It was the opinion of Mr. Fletcher Beach that intemperance in parents was one of the prominent causes of imbecility in children.

Among a number of other papers presented was one by Lawson Tait on a case of epileptic mania treated by oöphorectomy. Considerable relief was brought about by the operation. In the discussion Dr. Bacon said that he had castrated two male epileptics with the result in one case of great improvement.

SECTION OF PHYSIOLOGY.

The session began with a discussion on "The Evidence derived from Clinical Observations and Physiological Experiments as to the Seat of the Formation of Urea in the Human Body," opened by Prof. Arthur Gamgee, of Manchester. After going over each point in the subject at some length, he summed up his conclusions as follows: 1. It appears that the formation of urea does not occur, or occurs in insignificant amount (*a*) in the blood, (*b*) in the muscles, (*c*) in the nervous organs. 2. It is reasonable to suppose that in the glandular organs urea or its antecedents are formed. 3. The researches of various observers render it certain that urea is formed in the liver, though they do not warrant us in saying that the liver is the only seat of formation of urea. 4. Pathological observations establish a very strong presumption in favor of the liver being the organ in which the largest quantity of urea is formed. If properly pursued, pathological investigations afford the best possible means of proving conclusively whether urea is formed in the liver. 5. In order to obtain thoroughly satisfactory information from such investigations, it will be necessary that in future the total amount of nitrogen in the food shall be rigorously determined, as well as the total amount of nitrogen in the urine and the urea. Moreover, the participation of other organs, and especially the kidneys, in the morbid condition supposed to be connected with a deficient formation of urea, must always be carefully investigated.

A paper on "Urea in Blood and Muscle" was read by J. B. Haycraft, M.B. He found, on an average, in muscle, ten parts per 100,000; in blood, thirty parts. He believed urea to be a substance separated from the proteid food-stuffs before they underwent tissue assimilation. It was, in fact, a phase of digestion.

Papers were read "On the Presence of Leucin and Tyrosin in the Urine in Numerous Diseases," on "The Action of the Ribs in Forced Expiration," on "The Contraction of Striated Muscle."

A lengthy discussion upon "Sleep and Hypnotism" was opened by Prof. W. Preyer, of Jena. The speaker described his own theory of the cause of sleep; that it was due to the accumulation of fatigue products in the circulation, which took up the oxygen of the blood that was needed by the nerve-cells. He then reviewed some of the experiments and studies in hypnotism made by Dr. James Braid, and recently by Heidenhain, himself, and others. [A summary of these has appeared in the RECORD.]

DR. C. E. BROWN-SÉQUARD read a paper on the

EFFECT OF CERTAIN LESIONS OF THE BRAIN UPON THE EXCITABILITY OF THE MOTOR CENTRES.

He related a number of experiments which showed that there were a number of lesions of the brain which could produce absolutely opposite effects. One of these is well known as motor inhibition (or paralysis); the other he called *dynamogeny*. As an example he said that if a guinea-pig's head were suddenly crushed there would be paralysis of the fore legs, but very powerful convulsions in the hind-legs. He had found that lesions near the base of the brain would produce like results in other animals.

SECTION OF PATHOLOGY.

The event of this section was the address of the President, Sir James Paget, on "Elemental Pathology." The many difficulties surrounding the study of pathology, and the solution of its problems were referred to. Some of these difficulties might be lessened and light thrown upon many pathological problems by the study of the "Diseases and Injuries of Plants." He then described some of the diseases which he himself had studied. Hypertrophies were important because they were not related to function but simply to supply of nutritive material; thus the "ringing" of trees causes an hypertrophy analogous to that produced in the human body by the obstructed return of lymph. Atrophies are rare in plants but degenerations are common. Senile degeneration is well illustrated by the changes which take place in leaves preceding their fall. The degenerations found in the "sere and yellow leaf," throw light upon symmetrical disease; they show that neither blood or nerves are necessary to symmetrical decay. Again, the mode of decay and fall of leaves show that decay is not death, for dead leaves do not fall; the necessary antecedent changes are vital processes. The low vitality, but high scale of development of the fibre of the leaf-stem, illustrated the fact that many changes which we call higher developments are, from the point of vitality, degenerations. Bone was allied to calcareous degeneration, though it had acquired high uses.

Regarding the repair of

INJURIES IN PLANTS.

He said it was much less perfect than in animals, the reparative process rarely proceeding beyond the mere protection of the injured part. When plants are injured, layers of cork-cells are formed around, which may grow over the wound, or a gummy exudation is poured out, but the epithelium never re-forms. Still, trees show "the inevitable process of repair" going on in one known case in a pine tree, for one hundred and fifty years, without complete cure. This law, that an injury, which might occur at any age, and have no parallel antecedent in any ancestor, being indeed unique, should inevitably tend to become repaired in a particular way, indicated that there were other laws and properties at work in the body than those accounted for by heredity or evolution.

Two other topics were then taken up: inflammation and specific diseases. Inflammation was caused in plants by irritation. The gall was an illustration of the result of a specific inflammation, of which there were many kinds.

Sir James Paget concluded by urging his hearers to study some definite science apart from their professional work. "The astronomer studies astronomy in dark, stormy nights, and in the railway train, but his best studies are in the quiet of the observatory and with a calm, clear sky. Our life work lies in stormy nights and railway trains. If we desire to study calmly, and to profit, we must choose some subject which we can carry on apart from our professional work, during our leisure and holidays, which will yet afford lessons of surpassing value. Such a study is that of the diseases of plants.

The address, says *The Lancet*, was characterized by all the ease and clearness of diction, masterly force of language and felicity of illustration, which distinguish the speaker; and the audience showed no desire to break the spell which bound them in eager attention to the close.

Following the address, **Prof. Joseph Lister** read a paper of extreme interest upon

MICRO-ORGANISMS: THEIR RELATION TO DISEASE.

He first detailed the results of the experiments of Dr. Koch, of Wollstein. By ingenious methods of staining, that investigator had been able to detect not only the *bacillus anthracis*, which causes anthrax, but he discovered other specific micro-organisms. These were the *bacillus septicæmiæ* and the chain micrococus, the latter always causing gangrene when injected into house mice.

The *bacillus septicæmiæ* is an extremely minute organism, and would be invisible unless stained. Dr. Koch had been able to prove that it always caused septicæmia, never pyæmia, when injected into mice.

Professor Lister then described the micro-organism discovered by Toussaint in fowls suffering from fowl-cholera. This fowl-cholera is a highly infectious blood disease, characterized by swelling of the lymphatics of the neck, pericarditis, and duodenitis, but with no diarrhœa. The bacterium, claimed to be the cause of the fowl-cholera, is oval-shaped, multiplies by transverse constriction, and is about $\frac{1}{40000}$ of an inch in diameter. Pasteur has cultivated this organism, and has been able to modify it, so that by injecting the modified fluid he can cause a mild form of fowl-cholera—protective against a second attack. In the same line of inquiry, Dr. Greenfield, by experiments, had recently shown that if a guinea-pig be inoculated with the blood of a heifer suffering from splenic fever, the former animal takes the disease; if now the blood of the guinea-pig be inoculated in a healthy heifer, it will protect that animal against splenic fever. Professor Toussaint had performed similar experiments in regard to "vaccinating" for anthrax. But he went farther; he showed that the protective power is not conferred by inoculating any form of the *bacillus anthracis*, but by inoculating the fluid in which it had grown. Thus, he took blood from a case of anthrax, and by filtration and carbolic acid destroyed the organism; he then injected the filtered fluid into a healthy animal, and found it protected against the anthrax.

In conclusion, the speaker described the ingenious experiments of Dr. Buchner, of Munich, by which he had transformed, by cultivation, the *bacillus anthracis* into the hay-bacillus, and *vice versa*.

At subsequent meetings of the Section, papers on "Glomerulo-nephritis," by Dr. Leech, "The Pathology of Psoriasis," by Dr. Thin, "Congenital Neurotic Papilloma," by Dr. Cotter, and "Cerebral Embolism," by Dr. Dickinson, were read.

Mr. Jonathan Hutchinson read a paper, in which he reviewed the "errors which are liable to arise in the study of the part played by the nervous system in causing derangements of nutrition." Discussing the different views as to the

ACTION OF NERVES ON NUTRITION,

he divided them roughly into the view that all this action is vaso-motor, and to that which adds to this a special trophic influence. Before accepting the latter view, all hypotheses should be exhausted. He summed up the facts militating against the trophic hypothesis: the great rarity of some of the diseases which on the trophic theory should be common; the remarkable differences of these lesions supposed to be due to a common cause, and their great resemblance to lesions not of neurotic origin. Mr. Hutchinson gave a list of the conditions supposed to be dependent on trophic nervous influence. He then took up each one separately and showed the doubts that might be thrown upon its presumed neurotic origin.

In the discussion that followed, Drs. Brown-Séquard, Clifford Albutt, Dickinson, and others took part, most of them disagreeing with Mr. Hutchinson.

Dr. Buzzard read a paper on "Some Cases of Joint Affection in Locomotor Ataxy," which was admirably illustrated with photographs.

SECTION OF OPHTHALMOLOGY.

This Section was opened with a few introductory remarks from its President, **Mr. W. Bowman.**

Mr. Priestley Smith then read a paper on the "Pathology of Glaucoma," which was subsequently discussed by Mr. Cowell, Professor Donders, and others.

In a sub-section of otology, several valuable papers were read. Among them was one upon "Electricity in Ear Diseases," and one upon the "Treatment of Suppuration of the Middle Ear." A discussion upon the comparative value of mechanical aids to hearing took place.

Correspondence.

THE TREATMENT OF CYSTITIS.

To the Editor of The Medical Record.

Sir:—In the Record of September 4th I notice a report of the proceedings of the New York Surgical Society on the *value* of *operations* for the cure of *cystitis*, and while cordially agreeing with the majority of the gentlemen who participated in the discussion, that the great desideratum for the successful treatment of this troublesome disease is rest for the inflamed viscus, and the most absolute rest at that, my experience leads me to differ with them in regard to the manner of obtaining it.

During the past two years I have treated six cases of *cystitis*, two in the *male* and four in the *female*, and having lately adopted the principle that *complete rest* for the bladder was a *sine qua non* in the treatment, I cast about for obtaining it. Case No. 1, *male*, was of recent origin, and due to the extension of a gonorrhœa. Case No. 2, male, was a person of 40 years of age, intemperate, with an *enlarged prostate* and *stricture* of the *urethra* in its prostatic portion, the cystitis of a year's standing. Case No. 1, *female*, was also of recent origin, while cases 2, 3, and 4, *female*, had had a duration of one, two, and five years respectively.

The *treatment* in each case consisted in the retention of a soft *catheter* in the bladder, with the distal end attached to a urinal, so as to permit of the *free escape* of the urine on its entering the bladder. The introduction and changing of the instrument was attended with considerable pain, but once in position it answered every requirement in emptying that organ and producing perfect quiescence. I was careful to avoid the introduction of *too much* of the catheter, as it is liable to produce irritation and pain when brought in contact with the mucous coat. The medical treatment consisted in the administration of small doses of *ergot* by the mouth, every four to six hours, with the addition of *opium* when indicated.

In two of the *females* the continued use of the ergot produced uterine troubles, and I discontinued it in those cases, substituting hydrarg. submur. in alterative doses.

This was all the treatment employed, and all were attended with what I believe to be a permanent cure. The duration of the treatment was in one case seven days; in the remainder it ranged from twelve to twenty days. On the first introduction of the catheter the major symptoms, as pain, etc., at once subsided, and although there was considerable suprapubic tenderness left with recurring *aching pains*, none of the patients, after four hours' experience with the *catheter*, would consent to its entire removal till the inflammation and dysury had disappeared. Its constant use was not attended with any unpleasant consequences, and in the *females* it did not necessitate a recumbent posture.

Yours very truly,
M. F. Leary, M.D.

Gaylord, Kansas, September 13, 1880.

TREATMENT OF SPASMODIC ASTHMA.

To the Editor of The Medical Record.

Dear Sir:—In the smoky city of Pittsburg, quite well known throughout the United States as a resort for the bettering of those afflicted with asthma, we have a great deal of that disease. There are here many residents, natives of our city, sufferers from asthma. Yet there is in Pittsburg (Allegheny is only a suburb) the smokiest and heaviest atmosphere of any city perhaps on the continent. Dr. Hyde Salter, of London, says that an urban residence is preferred for asthmatics, and more especially that portion of a city in which the atmosphere is the heaviest and smokiest. Yet again, notwithstanding the opinion of so high an authority, it seems to me, through actual experience here, that those benefited by a Pittsburg residence are strangers, and are relieved according to the rule in this disease that travel and *change* will bring relief—the centres of relief being elsewhere as well as here.

I speak of pure nervous or spasmodic asthma—a disease in which I recognize two pathological elements: 1, *nervous spasm* of the bronchial tubes; 2, *hyperæmia*, approaching or amounting to inflammation. Difficult breathing involves all the physical signs. The *râles* have *a double character—id est*, they occur *both in inspiration and in expiration*. This I recognize, with Prof. Alonzo Clark, as a *sure sign* of spasmodic asthma.

In this disease I have tried, in vain, everything mentioned by the best authorities in therapeutics. Morphine I have relied on mostly; then nauseants and antispasmodics, *ad infinitum*.

On the first day of last April I was called to attend a lady, aged fifty years, whom I had attended at different times for over three years. On that day commenced the most violent attack of asthma she had ever had. Until the 10th day of May she had never left her room—scarcely ever the chair in which she sat. Breathing was difficult, without intermission. So much medicine had I given her that now I was beginning to fear the result in her case. Morphine quieted her, but as soon as I diminished its quantity the dyspnœa returned as bad as ever. At last her limbs became very much swollen; she became very weak, having had no appetite at all. I feared emphysema; I feared a termination of my case in dissolution. The lady had been a life-long sufferer from asthma; was a farmer's wife, but for over three years has been a resident of this city and a lady of leisure. As a last resort the idea arose in my mind, and I applied counter-irritation over the pneumogastric nerves from the upper part of the thyroid cartilage to near the upper borders of the clavicles, with tincture of iodine, even to blistering, when relief followed so rapidly and completely as to make me doubt that it was due to my application. In twenty-four hours the lady was greatly improved, and within forty-eight hours from the time of painting her neck *her asthma had disappeared entirely*. I was not satisfied, but had determined to paint her again so soon as the asthma returned. It has not yet returned. After the paroxysm had terminated, she took iodide of potash for several weeks, and has been better than ever before in her life.

The next case is that of a gentleman, æt. 42 years, a farmer. He has had spasmodic asthma all his life. His mother had it through her lifetime. He had been having attacks, growing worse every night, for a long time. I at once applied *counter-irritation over the pneumogastric nerves* in the neck, and placed him on iodide of potash. The night of the day on which I painted him (August 12th) he slept. He said that "he never saw relief come so quick. That last night was the most pleasant night he ever had."

Case III.—Gentleman, æt. 32, afflicted with spasmodic asthma since he was two years old. Had been having attacks every night. I painted his neck with iodine, making a streak about half an inch in width, and ordered potash internally. I cured the paroxysms.

All I have observed and all I claim for this treatment is relief of the paroxysm; and, thus far in my experiment, of the first paroxysm in which it is applied, because the patients have had no more since I first applied it, but all continue better.

These are three cases, consecutive, and all made better. It is a very limited number, but recollect they are consecutive cases of pure spasmodic asthma, which have occurred within five months in my practice, and as I may receive no new cases for some time, I speak of them for what it may be worth.

Very truly yours,
R. B. Faulkner, M.D.

Allegheny City, Pa.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from September 12, 1880, *to September* 18, 1880.

Moore, Jno., Major and Surgeon. Assigned to temporary duty as member of the Medical Examining Board in New York City. S. O. 194, A. G. O., September 11, 1880.

Ainsworth, F. C., Capt. and Asst. Surgeon. Granted leave of absence for six months. S. O. 196, A. G. O., September 14, 1880.

Price, C. E., Capt. and Asst. Surgeon. To report in person to the Commanding General, Department of the East, for assignment to duty. S. O. 196, C. S., A. G. O.

Medical Items and News.

Contagious Diseases — Weekly Statement. — Comparative statement of cases of contagious diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending September 18, 1880.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro spinal Meningitis.	Measles.	Diphtheria.	Small-pox.	Yellow Fever.
Sept. 11, 1880.	0	15	36	2	8	49	0	0
Sept. 18, 1880.	0	14	25	0	10	59	3	0

Diphtheria Spread by a Cat.—The following account is given as authentic :

"Three deaths from diphtheria have recently occurred in the family of Baldwin Gordon, who lives at the beach opposite Patchogue, L. I, under very remarkable circumstances. Some time ago a cat, which had been owned by a family several members of which were suffering from the disease, was taken to the Gordon house. While playing with this cat a little child of Mr. Gordon was bitten in one of its fingers. The wound caused intense pain, and was soon followed by a soreness and ulceration of the throat, which a physician pronounced to be diphtheria. Others of the family were taken with the disease and two of the children died. Mrs. Gordon, who was recovering from sickness, was seized with the disease and died. It is reported that still another member of the family has died. Physicians believe that the cat was suffering from diphtheria when it bit the child."

Successors to Prof. Paul Broca.—M. Trélat, Professor of External Pathology, Faculty of Paris, has been transferred to the Chair of Clinical Surgery, vacant by the death of Prof. Broca. M. Gavarret, Professor in the Faculty of Medicine of Paris, has been given the direction of the School of Anthropology, formerly in charge of the same distinguished man.

St. Francis' Hospital, N. Y.—A competitive examination of applicants for the position of junior assistant (two vacancies) on the house staff of St. Francis' Hospital, will be held at the hospital, 601 East Fifth Street, on Monday, September 27th, at 11.30 a.m. Candidates may present their credentials to Dr. Geo. F. Shrady, 247 Lexington avenue, New York, or to any other member of the Medical Board.

Workhouse and Almshouse Hospitals.—A competitive examination of applicants for the position of assistant house physicians to the Workhouse and Almshouse Hospitals (two vacancies) will be held at the residence of Dr. F. D. Weisse, No. 51 West Twenty-second Street, on Saturday, September 25th, at 8 p.m. R. Van Santvoord, M.D., Secretary of Medical Board.

Small-Pox in Harlem.—On the 16th inst. it was reported to the Board of Health that a child in Harlem was suffering from a disease suspected to be small-pox. Dr. Taylor, the chief of the Vaccination Bureau, found it to be a genuine case of small-pox. The child was in the first stage of the disease. The house contains six families, and Dr. Taylor having been informed that on an upper floor two infants were sick from measles, found them suffering from small-pox. He learned that there had been five cases in the house in four weeks, and that one of the patients had died, and the physician had not recognized the disease. The contagion was traced to a case that occurred some weeks ago, but whence it came was not ascertained. Arrangements were made to disinfect the house. The children were removed to the Reception Hospital.

Fasting Frogs.—Dr. H. S. writes: About the middle of October, 1879, I put two common frogs into an earthen jar, with a little water and a stone in the centre, covered the jar closely, intending to use them in the winter to illustrate the circulation of the blood under the microscope. I supplied them with water once during the winter, and finally forgot them until the 15th of July last. Upon opening the jar I was unexpectedly pleased to find my frogs alive and well, and able to leap vigorously when I turned them out. They had lived, honestly, without food nine months.

The Floating Hospital made its last trip, September 16th. It has made forty trips during the past summer, and has carried about 27,000 mothers and children.

Otalgia and Irritation of Trigeminus.—Dr. Sexton, of this city, writes : In your report of the transactions of the American Otological Society, in the Record of June 11th, I am reported as saying—"Dr. Sexton was inclined to believe that the collections of cerumen in the ears had a good deal to do with the causation of mastoid neuralgia." This paragraph alludes to an opinion expressed respecting the neuralgia experienced in a case under discussion. What I said was this : that the neuralgia in this case probably had its origin in the irritation of the dental filaments of the fifth pair of nerves; the irritation being reflected to the temporal region was the cause of the severe pains experienced by the patient.

Medical Honor in Philadelphia.—According to the *Philadelphia Medical Times*, consultations are comparatively very rare in Philadelphia. The reason assigned is that the young men are afraid to call in their elders because the said elders allure the patients from those whom they are called to advise. What between the old men being thus crafty, the young men inexperienced, and Dr. Buchanan's diploma-mills, medical matters look rather dark in the Quaker City.

Gonorrhœa and Micrococci.—The latest fancy is that gonorrhœa is due to specific micrococci. So the urethra is plugged with a half-foot germicidal bougie, which is allowed to melt while the patient lies on his back. Then the gonorrhœa is cured in the usual way with boracic acid or a two-grain injection of sulphate of zinc. The brilliancy of this process is shown by the fact that in favorable cases the disease is "arrested" at the end of one or two weeks.

Our Natural Life.—Dr. Farr, who is perhaps better able than any other authority to give an opinion upon this point, has estimated the natural lifetime of man to be a hundred years. Old age may be said to commence about sixty—with some a little earlier, with others a little later.

A Quintet of Babies.—On September 18th Mrs. Hazzard, of Monticello, Ill., is said to have given birth to five children. They were all alive at last accounts.

Professor Giovanni Polli, of Milan, died recently after a long illness. Professor Polli is best known for his researches upon the subject of fermentation. The value of sulphurous acid, the sulphites, and of boracic acid as anti-fermentatives, was shown by him.

Professor Rizzoli, of Bologna, recently died at the age of seventy years. Just previous to his death he had made a donation to the city of Bologna of 1,250,000 francs, for the erection and maintenance of an orthopedic hospital.

Pilocarpine in the Treatment of Intermittent Fever.—The experience of Dr. A. L. Davis does not confirm the virtues of pilocarpine in intermittent fever, alleged by Dr. Griswold. It sometimes aborts the attacks, but oftener makes the patient so sick and prostrated that his condition is worse than if he had had the chill.

A Kidney was Extirpated recently at Charing-Cross Hospital by Mr. Barwell. The patient was a girl of sixteen, who had long suffered from severe suppuration, which had greatly reduced her strength. The kidney was large, weighing six and three-fourths ounces, tuberculous and suppurating. Since the operation the patient has been doing well.

Vitality of Spermatozoa.—In a mixture devised by Byasson, spermatozoa have been kept alive for twelve days, at a temperature of 36° C. The mixture is composed of: water 1,000 grammes, the white of one egg, and fifty-nine grammes of phosphate of soda. The liquid makes a useful injection in cases where sterility is due to excessive acidity of the utero-vaginal secretions.

Progress of the Provident Dispensary System.—The Hospital Out-patient Reform Committee of the British Medical Association have made their report through the chairman, Mr. Timothy Holmes. It is the opinion of the committee that the out-patient departments of the hospitals should be abolished for the most part, as they now exist, and should be made only consulting-rooms. In order to render this possible, however, some provision must be made for the poor who have been flocking to these institutions for so many years. The committee propose a scheme which shall secure the co-operation of the great friendly societies in founding a large institution or confederation of provident dispensaries. The plan for this has been fully matured, and steps are now being taken to carry it out.

With regard to the question of the abuses of medical charities, the committee give it as their opinion that the out-patient departments of the hospitals and the dispensaries will never be adequately reformed until the working classes can be made to see that ordinary illness, like other accidents of humanity must be provided for by their own exertions, and that it is only under special emergencies that charity ought to be brought into play; and until the medical profession can be brought to see that a great proportion of the ailments which are now treated in the dispensaries are unfit for such treatment, and can only be successfully managed by medical men having the same relation to their patients as private practitioners have in other classes of practice.

Therapeutic Uses of the Bromides.—Rosenthal gives the following summary on this subject:

Bromide of potassium ought to be frequently suspended, because it produces loss of tone in the stomach, debility, and precordial pains. While it, in small doses, increases the appetite, in large doses it disturbs it, and consequently should be given largely diluted with milk.

Bromide of sodium is a preparation very salt and better tolerated by the stomach, and should be given in preference to old people, nervous people, and children.

Bromide of ammonium is good in epilepsy and affections of the glottis, but is not superior to the other bromides.

Bromide of camphor moderates the action of the heart, and is good in alcoholism, in doses of fifteen to thirty grains.

Bromide of zinc can not be given in pills and is inferior to the other bromides.—*Va. Med. Monthly.*

In New York the favorite bromide is, probably, bromide of sodium. The fact about the bromides is, that one is just as good as another, the difference being in strength, not in quality. By varying the dose of bromide of potassium, for instance, nearly all the effects of the other bromides can be obtained.

Lengthening the Lecture Courses of Medical Colleges.—The Medical College of Virginia announces that its annual lecture course will now continue for nine months. It adopts the graded system also. A similar extension of time is to be adopted, it is said, by the Medical College of the University of Virginia.

Ergot in the Dysentery of Children.—Twenty-one cases of dysentery of children, reported by Dr. G. L. Magruder, of Washington, were treated with fluid extract of ergot, five to twenty drops four or five times a day. Almost every case immediately responded to treatment, and was either entirely relieved or much improved.—*Va. Med. Monthly.*

Another Medical College.—The Memphis Hospital Medical College and Medical Department of the Southwestern Baptist University, has been established, to the gratification, it is suggested, of the profession and students of the Southwest. Its location is opposite the City Hospital of Memphis, which institution it will utilize.

A Case of Counter-Prescribing on the part of a Chicago druggist is reported by the *Chicago Medical Review*. A lady asked the apothecary's clerk for a dose of chloral hydrate. The young man gave her two hundred and forty grains. She took the dose and was barely rescued from death by the efforts of a physician.

Treatment of Chronic Eczema.—Avoid the use of soap as this is irritating. Twice a day, bathe the part in an aqueous solution of borax, one ounce to the pint. Dry without friction and freely apply the benzoated zinc ointment, then bandage the part firmly with old dry muslin which has been previously wet with a saturated aqueous solution of borax. Over this apply a bandage of oiled silk in such a manner as to exclude the air perfectly. Let the bowels be kept regular. In the majority of cases eczema can be promptly cured by the simple exclusion of air. Eczema of the fingers will generally yield in a few days if the air be excluded by the ordinary rubber cot.—*Chic. Med. Rev.*

Death of Dr. Frank H. Davis.—We regret to learn of the recent death at Chicago of Dr. Frank H. Davis, son of Dr. N. S. Davis. He was a young man, and gave great promise of success in his profession.

THE CAUSE OF MISS NEILSON'S DEATH.—The London *Times* of August 26th publishes the following letter:

I take the liberty of asking room in your columns for a word in regard to the death of the lamented Miss Neilson. For the last five years I have had the charge of her health during her visits to Paris, one of the treatments running through a period of four months. The disease from which she suffered principally was gastralgia—one of the forms of dyspepsia attended with neuralgia of the stomach, a form extremely fantastic in its coming and going, and, in her case, quite as dependent on moral causes as on errors of diet. The last fatal attack in the Bois de Boulogne was evidently one of her usual attacks of gastralgia, which might have been relieved then, as it often had been before, by a free use of morphine. The unfortunate lady sent her maid for me at 7 o'clock, but to my great regret I was absent that evening on a visit to my family in the country, and did not hear of her illness till I heard of her death. At 3 o'clock in the morning, twelve hours from the commencement of the attack, during a most violent recurrence of the pain, she suddenly ceased to complain, went into a state of syncope, and died in the syncope. The post-mortem examination made the next day by Dr. Brouardel, Professor of Legal Medicine at the Medical School of Paris, and now one of the first authorities in Europe in legal medicine, disclosed the extraordinary fact—one of the rarest in the history of medicine—that in her writhing she had ruptured a varicose vein in the left Fallopian tube, and had died from internal hemorrhage. Two quarts and a half of blood were found in the peritoneal cavity, and the ruptured vein presented an orifice of from four to five millimetres in diameter.

Very truly, etc.,
W. E. JOHNSTON, M.D.

NO. 10 BOULEVARD MALESHERBES,
PARIS, August 22d.

DR. J. MARION SIMS has recently been decorated with the order of Leopold I. by the King of Belgium. The decoration was offered him seventeen years ago, but the American minister refused to let him receive it because of the doctor's Southern sympathies.

DR. A. BARTOL ON THE LATE DR. JACKSON.—The hand or the mind he had in those two most important of modern discoveries, telegraphy and etherization, is the subject of a controversy never put quite at rest, and which I have no wish to revive, although, now he is gone, it deserves some reconsideration more impartial and judicial than, in the conviction of many of his friends, it has yet received. Particularly in regard to anæsthesia, there must be men living, once his intimate associates, who, so far as they know the circumstances, ought as witnesses to take the stand.

He was a man whose self-respect did not allow him to waive his own claims, and of course his attitude could not please those who were inclined to reduce them to the lowest point; but never was a more honest person than he, and it were a shame to be prejudiced by anybody's ingenuous consciousness of his merits against their well-grounded truth. I am aware of the point made that there is no actual invention without a demonstration to the eyes and application to use. Says Dr. Paley, writing on a different matter: "He only discovers who proves." But practical men carry this dogma too far when they disparage as worthless the original suggestions but for which no experiment would have been instituted, far less issued in success. At the time of the strife, in a public and published discourse, with such lights as I had, however feeble by publicists they may be held, I was constrained to assign the inventive merit as to the use of sulphuric ether to him.

But Dr. Jackson was simple as a child, and veracious like the sun; and when I asked him if he at the outset had foreseen the immense consequences of his theory in surgical operations without pain, he replied that in the imperfect starting of such a business no man could; and I suppose no complete horoscope of deduction did even Newton or Kepler hold!

BATHING AFTER MEALS.—Two cases, reported by Dr. Naegli in the *Swiss Medical Journal,* illustrate the truth of the prevalent belief that it is dangerous to go in bathing when the stomach is full. The cases were alike in their history. One was that of a boy of fourteen, who ate a hearty meal and then went in the water for a bath. While swimming along with a comrade, he suddenly gave a cry and sank under the water. He was speedily brought out on shore and the usual means of resuscitation employed. These utterly failed, however. Fearing some obstruction, the boy's trachea was opened and pieces of food were found in it. These were removed in part; but it was not sufficient, and the boy died. The other case had a similar history. At the *post-mortem* a portion of the contents of the stomach was found in the trachea and bronchi.

DEATH OF DR. HEBRA.—The funeral of the distinguished dermatologist, Baron von Hebra, whose death occurred recently, was very largely attended by his many friends. The ceremony was, by his wish, quiet and unostentatious. Many wreaths and crosses were piled upon his tomb. His students added to these one of great size, bearing the inscription:

> "Wer im Gedaechtniss seiner Lieben lebt,
> Der ist nicht todt, er lebt nur fern,
> Todt ist der, der vergessen wird!"

ENGLISH PHYSICIANS ADVOCATING CREMATION.—At the last meeting of the British Medical Association a paper was read on cremation. At its conclusion a memorial was drawn up, addressed to the Home Secretary, and praying that permission be granted for the practice of cremation. The memorial is signed by Mr. T. Spencer Wells and many other prominent physicians and surgeons.

ANTISEPTIC INCISION OF THE KNEE-JOINT.—A paper on this subject was read by Dr. G. R. Fowler, before the Kings County Medical Society, August 17th. Basing his remarks upon sixty-six collected cases treated by the Listerian method, he comes to the following conclusions regarding the favorable effect of that method upon the operation:

1. The total mortality in excisions of the knee-joint has diminished about one-third since the introduction of Listerism into surgical practice.
2. The majority of the fatal cases operated upon antiseptically died of a pre-existing disease or complication.
3. Fatal cases directly referable to the operation, and from causes such as are now considered preventable by antiseptic treatment, are reduced fully fifty per cent.

Statue to Dr. Paul Broca.—The Anthropological Society of Paris has appointed a committee to collect subscriptions for a statue to the late Dr. Paul Broca.

Post-partum Hemorrhage.—Dr. J. T. Crow, of Carrollton, Ill., writes: "I wish to ask Dr. Forest, first, how much of the effect (in his cases of post-partum hemorrhage, reported in the Record of September 4th) was due to the iodine, and how much to the alcohol of which the tr. iodine is largely composed? Second, I wish to ask Dr. F. and others to try injection of alcohol in post-partum and other hemorrhages; for, if it will answer the purpose as well as tr. iodine, it is certainly as little hurtful, and much more apt to be found quickly when needed, especially in country practice."

American Academy of Medicine.—The fifth annual meeting of the Academy will be held in Manning Hall, Brown University, Providence, Rhode Island, on Tuesday, September 28th, at 4 P.M. The address of the President, Dr. Frederick D. Lente, of New York, will be delivered at 8 P.M.

Another Medical Journal.—The *St. Joseph Medical and Surgical Journal*, a monthly journal, edited by Dr. J. P. Chesney, has been sent to us. It intends to be the exponent of the legitimate medical thought and practice throughout the great Northwest. The editor writes his salutatory with vigor and good sense.

The Audiphone and the Vulcanite Denture.—It has been found by Dr. Osman, of Baltimore, that in deaf persons with false teeth the vulcanite denture acts better than a gold or silver plate, when the audiphone is used. This conclusion is confirmed by Dr. Lawrence Turnbull. The latter gentleman says, as to the alleged injury which vulcanite plates cause, such as increasing deafness, producing irritation, etc., that such things have not come under his observation. Regarding the success of the audiphone, he says: "It has been stated by the agents of the inventor that in the city of Philadelphia about sixty deaf individuals have been benefited by the audiphone, and now employ this means of improving their hearing. This number, I judge, has been much reduced of late, and the few, to my personal knowledge, who continue to employ the instrument probably do not exceed five. Some of these are decidedly benefited by its use, and are able to enjoy the comforts of home—even a baby's voice, which they never heard before. In one case, a reporter, from his being able to hear with this instrument, has been advanced in his profession, showing that it certainly increases the acuteness of hearing." In ten cases of deafness tested by Dr. Turnbull, only one was improved by the audiphone, while six could hear better with the ear-trumpet.—*Phila. Med. Times.*

A Distinction in Infanticides.—The law in Schwetz, Switzerland, as just adopted by the local legislature, very singularly makes a distinction between legitimate and illegitimate children. The crime of infanticide will be punished with death only when the victim is a child born in wedlock.

Death of Dr. Wm. W. Williams.—The death is announced of Dr. W. W. Williams, at Cheltenham, August 6th, at the age of 65. Dr. Williams was for many years honorary secretary of the Medico-Psychological Association. He was intimately connected with the establishment of the present lunacy system in England.

Two Abortionists and one herbalist in England have recently been convicted of murder and sentenced to imprisonment for life.

Richard Wiseman on Immediate Amputation.—In the middle of the seventeenth century, Richard Wiseman, Chirurgeon to Charles II., laid down the following rule regarding immediate amputation. It will be seen that he anticipated the conclusion which, after long discussion, modern surgery has reached: "In heat of Fight, whether it be at Sea or Land, the Chirurgeon ought to consider at the first dressing, what possibility there is of preserving the wounded Member, and, accordingly, if there be no hopes of saving it, to make his Amputation at that instant whilst the Patient is free of Fever," etc.—*Annals of Anatom. and Surg. Society.*

Metallo-Therapy for Diabetes.—Iron, according to M. Burk, one of the apostles of metallo-therapy, is the metal which, taken internally, relieves diabetes. A case is related illustrating this action. A diabetic patient, who had already lost one eye from cataract, put himself under a course of treatment at Vichy, drinking the waters of the Lourdy springs. His health improved in every way, and he was enabled to live for many years. M. Burk reasons as follows: The Lourdy spring contains iron; iron is the metal which relieves diabetes, and hence metallo-therapy is entitled to the honor of the cure in question.

State Provision for the Families of Medical Men.—Some time ago a proposal was made in the Chamber of Deputies of France that the state should make some regular provision for the families of medical men who died from diseases contracted while in the exercise of their profession. A commission was appointed to investigate the matter. It did so, and reported favorably to the project. There were great prospects that it would become a law. Recent journals, however, state that the Minister of the Interior does not approve of the plan, and it has been laid aside, therefore, for the present.

A Case of Acute Pneumonia is reported in the St. Louis *Courier of Medicine*, where the temperature reached 110°. The patient recovered.

HISTORY OF THE BLOOD-CORPUSCLES AND THEIR RELATION TO THE MARROW OF BONES.*

By THOMAS HOLMES CATHCART, M.D., Ph.D. (Univ. Penn.),

LIBRARIAN AND EX-RESIDENT PHYSICIAN TO THE EPISCOPAL HOSPITAL, PHILADELPHIA.

The knowledge of the human body, the preservation of health, the recognition and cure of diseases, are objects of too great importance to mankind for me to doubt but that any attempt to promote them, however small, would meet with a candid and indulgent reception from the profession. An inquiry into the intimate nature of the blood, more especially of its corpuscles, it is presumed, will be thought in a particular manner interesting, since there is no part, no organ of the human body, upon which more physiological reasoning has been founded, nor any from which more inferences have been drawn for the detection and treatment of disease. And as the inquiry is made from the accumulated observations and experiments of centuries, aided mostly by those of the last ten years, it is hoped that the conclusions made from them will meet the test of a candid examination, and lead to further observations and discoveries—"tempora mutantur et nos mutamur in illis." The saying attributed to Cuvier, "le sang est chair coulant," expresses very fairly our appreciation of the relations that subsist between the blood and other tissues of the body. A change in the former, we know, almost necessarily involves a change in the latter, and each of the vital actions of the latter exerts some influence on the former. It is manifest, therefore, that an acquaintance with it is absolutely essential to the phenomena wrought in the tissues by disease; and if any evidence of the life of the blood is wanting, it will be abundantly furnished by the properties of the corpuscles, which I shall shortly describe quite independently of those vital endowments so beautifully shown by Hunter,[1] Beale,[2] Cohnheim,[3] and others. Well, indeed, might Harvey[4] describe the blood as the "vital spark," to which every other part of the body is more or less subservient, the "first to live, the last to die."

Each successive addition adds to our knowledge; the result of all our worthier subsequent inquiries, the sum of all the best ascertained facts up to the present day, have either but confirmed or added to Harvey's masterly proofs of the importance of the blood. Now, it might be interesting, perhaps, to give an elaborate account of the ideas men early entertained respecting this important tissue; but as most of these are so absurd, and the labor to collect them so great, it may here be agreeably dismissed. Suffice it to say, however, that not only was the circulation totally unknown, not even suspected by them, but the blood itself held no place of any value in the curious speculations that formed the basis of their systems. Its existence in the economy was regarded rather as an accident than as a means of nutrition, and the vessels in which it is contained were supposed to subserve quite a different end. Hippocrates[5] did not discriminate at all between arteries and veins. Aristotle[6] did recognize the difference, but yet held the blood as subsidiary to the vessels. He differed from his predecessors in maintaining that the veins arose in the heart,[7] while they maintained that they arose in the head. Galen endorsed essentially the same ideas, except that he looked upon the liver as the source of the veins.[8] So great was the authority of these men and the reverence for them during the middle ages, that none dared to dispute them, and their empty assumptions held their ground. Even Mondino,[9] who dissected at Bologna, 1315; Achillini,[10] Scarpa,[11] and Messa,[12] in Italy; Sylvius[13] and Stephanius,[14] in France; Vesalius,[15] a native of Brussels; Fallopius,[16] his successor at Padua, and Eustachius,[17] said naught to contradict them. The unfortunate Servetus, 1552, was the first to distinctly speak of a circulation now termed pulmonic; but the value of this truth is, in his work, much clouded by the traditional fancies of the age concerning the "vital spirit." For this assertion, Servetus and his book, "Christianismi Restitutio," were burned the following year, and only two copies of this curious book are now extant. His discovery would, no doubt, have fallen into oblivion, had not Rialdus Columbus,[18] 1559, publicly corroborated it. Light was now dimly dawning upon anatomists, and it seems queer to us, in this progressive age, that when, besides the above. Andrew Cesalpinus[19] noticed the swelling of veins below ligatures, and Fabricius,[20] of Acquapendente, showed that the valves of veins discovered by Sylvius opened toward the heart—it seems queer, I say, that Fabricius did not discover the circulation, but left that glory to be reaped by his pupil, William Harvey,[21] 1616–1628. So true is it, observes Cuvier, "that we are often on the brink of a discovery without suspecting it;" so true is it, I might add, that a certain succession of time and of persons is generally necessary to familiarize men with one thought before they can advance to that which is next in order. The immediate reception of Harvey's[22] discovery was not at all gratifying to him, and it was not until 1658, when the blood-corpuscles were noticed, that men began to consider the blood as ministerial to high agencies in the economy.

This detection of the blood-corpuscles by Swammerdam[23] in the frog, brought about by the introduction of the microscope into anatomical researches, was the starting-point of all modern investigations concerning the cellular elements of the blood, and as it is these in their morphological transformations, in their dependence on other constituents, other organs of the body, their significance and value in disease, and their intimate relationship with pathological processes and conditions, to which my subsequent pages will be devoted, I cannot do better than to give a brief *résumé* of the analysis of the blood as taught by the ablest and most authoritative physiologists of the present day. Then we can proceed to consider more aptly from early up to recent times the evolution of ideas regarding the blood-corpuscles as "morphological values," their birth and development, their relation to certain peculiar diseases, and the observations and facts corroborative of these. The blood essentially consists of cells and a fluid intercellular substance; the former constituting the cruor or corpuscles, the latter the plasma or liquor sanguinis. The proportion of these to one another is: plasma, 487; cruor, 513[24]. Now, the plasma[25] is composed of fibrin-forming elements,[26] albuments, salts, water; the cruor of corpuscles. The approximate quantity of these may be seen from the following compilation:

So much for the general analysis of the blood, as we will now direct our attention to the corpuscles, red and white, with which our subject is more intimately connected.

These, from the singularity of their appearance and organization, have attracted an unusual share of attention, and have been the subject of almost innumerable observations and experiments. They were discovered by Swammerdam in 1658, afterward by Malpighi[32] in the hedge-hog, in 1661, who at first thought them to be globules of fat. Leeuwenhoek, in 1673, detected them in human blood and examined them very critically, and it was from this time that their study commenced in earnest. They were first described as globules floating in the liquor sanguinis; but, as observations were multiplied, errors and absurdities were advanced *pari passu*. Leeuwenhoek himself invented a fanciful hypothesis, which had a long and powerful influence over the most enlightened of physicians—that the red corpuscles of the blood were composed of a series of particles descending in regular gradations: thus, each corpuscle was supposed to be made up of six particles of serum, and each particle of serum of six particles of lymph, etc., etc. This hypothesis,[33] for which to our mind there is not the slightest foundation, was so suited to the mechanical genius of the age that it formed the basis of many learned speculations, and even a feature in some pathological ideas of Boerhaave. It maintained its hold until the time of Haller, when it was replaced by another one.

Next to the observations of Leeuwenhoek, those of Hewson[34] were the most elaborate, and had at least the appearance of great accuracy. He described the "red particles" as consisting of a solid centre surrounded by a vesicle filled with a fluid. He informs us that by adding water to them they swell out. He also mentions the effect of chemical agents on their form,[35] etc. Hunter differs essentially from Hewson in his account of them. He is silent respecting the nucleus and investing vesicle. He does not regard them as solid bodies, but as liquids possessing a central attraction, which determines their figure. The red corpuscles were also examined by Torré,[36] Monro, and Dr. Young.[37] Torré supposed them to be flattened, annular bodies composed of parts cemented together. To Monro they exhibited the appearance of circular flattened disks with a dark spot in the centre—due, he conceived, not to a perforation, as Torré had imagined, but to a depression. The account which Young, 1813, gives, corresponds to that of Hewson. He remarks that if the "globules" be viewed by a strong light, they will appear like simple transparent spheres. He found that in the human subject they were flattened and have a depression in the centre,[38] as described by Monro.

The form or shape of a mature red corpuscle is circular and flattened—a disk, first noticed by Hewson, but afterward denied, and only established by Young as above mentioned. This disk is rounded at the margin, biconcave or flat on the broad surfaces, most generally the former. It is this biconcavity which produces the central spot that caused so much perplexity among the earlier observers. Some, as before mentioned, insisted that it was a nucleus, others that it was a hole, and hence the corpuscle a ring. But now we know that, by watching the corpuscle roll over on its edges, it will be seen that the central spot is but a depression. This can be made to disappear by the addition of a fluid. The brightness or darkness of the spot is merely dependent on the focus of light. It must be remembered, however, that in 1827 Dr. Hodgkin and Mr. Lister[39] made the statement: "Our observations are at variance with the opinion long since formed by Hewson, that these particles consisted of a central nucleus enclosed in a vesicle composed of colored matter, and which, though refuted by Dr. Young, has since, in a modified form, been revived in England by Sir Ed. Horne and Bauer,[40] and by Prevost and Dumas[41] on the continent. This is their statement, which refers to their examinations of the human blood-corpuscles, and so accurate was it that it ought at once to have dispelled forever any more belief in the imaginary nucleus of the blood-disk of man. Still, it does not appear that their observations were pushed far enough to enable them to perceive the accuracy of Hewson's statement; for, while they had examined mammalian blood, he had investigated that of oviparous animals. Thus it was that all parties were left to the bewilderment of half-truths—so fruitful a source of error, so conscientious in themselves, but still so confounding. For the descriptions of all them were correct and real when confined, as they ought always to be, to the same class of animals.

The red corpuscle of man and other mammalians has no nucleus—nothing so evident as that seen in the corpuscles of the oviparous vertebrates. The mistake of describing a nucleus in the red corpuscle of the mammalians arose from the central spot, due to biconcavity and varying focus, and from the observers applying what they so plainly saw in the ovipara to man and mammalia. And this error prevailed to the year 1839, though Gulliver[42] had endeavored to correct it, while Müller,[43] Krause, Gerber,[44] and others had satisfied themselves that the nucleus existed in the red corpuscle, and Prof. Wagner[45] was expressing doubts on the subject. In England, Dr. Martin Barry was publishing his engravings in the Philosophical Transactions, of what he regarded as positive proof of this nucleus, and the same idea was confidently asserted in Dr. Todd's Cyclopædia of Anatomy. Lastly, in 1842 and 1845, Donné[46] on the continent, and Mr. Wharton Jones[47] in England, fully acquiesced with Dr. Gulliver[48] as to the fact of the difference in question between the mammalian and oviparous blood-corpuscle, and thenceforth this important subject—"the vexed question of a nucleus," as Mr. Jones appropriately termed it—was finally settled. And it is no wonder that such mistakes were made, for we can now readily understand, with our improved microscopes and more thorough knowledge of optics, that the corpuscle being biconcave, the foci of its centre and periphery are not at the same point, and hence, that when one is bright the other is dark; that when the object-glass is "beyond the focus," the periphery is clearest and brightest, and the centre, no longer in focus, is dark; and that when the objective is "within the focus" the centre is bright and the periphery dark.[49]

In the course of these inquiries, it might have seemed insignificant and of no consequence whether the red corpuscle had or had not a nucleus; but when it is evident that it rises to the dignity of a comprehensive truth—namely, that mammalia, camelidæ and auchenia excepted, do not have it, while all oviparous vertebrates do have it, its value can be appreciated.

For many years the red corpuscles were indisputably held to have a definite cell-wall; but some time past, notably in the last few years, a change in opinion has been made, and now in most of the text-books on physiology it is expressly stated that they do not have one. The peculiarity and persistence of the form of these corpuscles, their behavior on the application of pressure, and the presence of one line only to distinguish the difference in density of the contents of the cell and its surrounding medium, when two should exist—namely, one to denote the difference in density or degree of refraction of the cell contents and its wall, and a second to show a like difference between the cell-wall and its surrounding medium, whatever that may be—are certainly in favor of the latter view. Investigations of Dr. Jos. G. Richardson[50] seem to go to contradict this view and to hold to the old.

The conclusions reached by him were based upon observations on human corpuscles, and on those of the menobranchus or proteus. Objective used, $\frac{1}{50}$ inch. He states and clearly proves the corpuscle to be composed of "hæmato-crystallin freely soluble in water," and a second substance, "whitish in hue and insoluble in water." But when he considers this latter as constituting a cell-wall, it is then that we cannot but differ from him. He bases this view on the appearance presented by the crystals of hæmato-crystallin, or, as he says, "the folded edges of the capsular membrane will be seen supported by the crystals like a washerwoman's clothes-line upon its prop." This, after many trials, we have been unable to see. Again, he remarks that he broke the cell-wall by means of fine needles, when immediately the hæmato-crystallin passed out and the "cell-wall immediately shrunk together and became twisted on itself." Again, he thinks that "the wrinkled appearance" presented by drying, and the swelling and change of form produced by the absorption of water in the corpuscles, prove to him conclusively the existence of a cell-wall.

The criticism of Dr. Richardson's deductions, ably stated by a reviewer, lies in this: "that because these phenomena are compatible with the supposition that there is a cell-wall to the corpuscle, he thinks they cannot be compatible with any other view." For the form of the corpuscle produced by the crystallization of the hæmato-crystallin is just as compatible with the non-existence of a cell-wall as his view is. So also the "wrinkled appearance," which will adapt itself to any theory that acknowledges absorption of a liquid. And lastly, the "twisting or dimpling in" does not in the least disprove the existence of a "sponge-like" stroma (Rollett).

Indeed, the explanation of Rollett[51] of the structure of the corpuscles is most consistent with the observations of microscopists. He considers the corpuscle as formed of "oikoid" (analogous to stroma), which takes up the hæmato-crystallin in solution—but that there is no cell-wall. That something—name it "stroma," "oikoid," "shell," which you please—does remain when the coloring matter is dissolved out, no one can deny. This is better named structureless, jelly-like "frame-work," which it may, but to us undoubtedly is, though Dr. Richardson considers it to be the cell-wall. Without disputing the accuracy of his observations or the sincerity of his belief, we are yet inclined to maintain that the red cells are without a wall. And in this view we but follow that of the highest authorities of the day. Thus, Schaeffer[52] states that "they present a perfectly homogeneous appearance; but by reagents it is visible that they are composed of a stroma which is colorless and gives shape to them, and a coloring-matter hæmoglobin which can be crystallized." Again, Frey[53] observes that "they display but little variety in size or contour;" "that they are sharp, delicate, without a cell-wall." And further, "a cell-wall is certainly not present in the blood-corpuscle as their spherical segmentation indicates, and Rollett's discovery, also that two of them may coalesce together by a discharge of electricity." Flint[54] says that the red corpuscles "are perfectly homogeneous, have no nuclei, and are not provided with an investing membrane." "Few, if any, have demonstrated its presence, but only suppose it to exist, because the corpuscle swells by imbibition of fluids." Dalton[55] also remarks that "observations so far display them to be homogeneous; the most careful examinations fail to show the evidence of an external envelope, though authorities such as Richardson and Kölliker[56] still maintain it to exist." Again, Sanderson[57] states distinctly that "the phenomena mentioned of the properties of the corpuscle distinctly show them not to be vesicular." Kuss[58] corroborates these opinions and adds, that "the red corpuscles have no nuclei nor any envelope, but a thin limiting layer condensed by age more than the central parts."

[56] Kölliker: Manual of Mic. Anat. London, 1860. Art. Blood.

Now, we have mentioned various views and observations as to whether the red corpuscles are homogeneous without a cell-wall or not, and we have stated our own ideas as to the elasticity of the corpuscles, their persistence in preserving their form, their actions when subjected to pressure and reagents, and we think that the aggregate evidence proves the cell-wall to be absent, and that its existence was inferred rather than proven. But besides the red corpuscles we have also another corpuscle in the blood, to wit, the white. This was first distinguished by Hewson and Senac,[59] 1775, and clearly described by them, but did not attract much attention until Addison,[60] 1843, asserted their importance as parts of tissues and secretions. His views were, however, too far in advance of his age to be rightly appreciated. His observations were followed by those of Wharton Jones[61] and Waller, in 1846; by Von Recklinghausen, in 1863, who studied their amœboid movements; Schultze, in 1865, and Virchow and Cohnheim, 1867, brought them into great repute by their theories respecting inflammation. Since then they have become the objects of microscopic research, and we know them to be of importance, judging not only from their prevalence in the animal kingdom, from their early appearance in the embryo, and from their presence ever afterward in the blood, but from their rôle in disease, their migrations and diapedesis in certain pathological conditions, their transformations in the formation of tissue, repairs, and new-growths, and their enormous increase in some peculiar diseases.

They are more uniform in size and shape than the red corpuscles. They are specifically lighter and circulate less rapidly than these. They creep along the outside of the current and seem to have an especial attraction for the walls of the blood-vessels. In their appearance they are circular and nearly spherical. They have a grayish, pearly[62] look. Robin[63] termed them leucocytes on account of their white appearance, and believed it a good term, because bodies like them were found in the lymph, chyle, semen, colostrum, vitreous humor, saliva,[64] and hence were not peculiar to the blood alone. Flint[65] states them to be filled "with granulations, pale, a delicate outline, and of two or more nuclei." Dalton,[66] that they are destitute of coloring matter, and have a glistening appearance. That they are nearly spherical, and consist of a "soft, viscid, colorless, finely granular" substance, "containing one or more nuclei." The amœboid movement noticed by Recklinghausen,[67] is only evident when they are withdrawn from the vessels. Gulliver[68] considered them to be "pale globules containing a nucleus." And these descriptions of their appearance are in perfect accord with those of the present time, and with our own observations. For Frey[69] describes them "as finely granular, spherical," the granules showing no molecular motion. Beale[70] looks upon them as "masses of structureless germinal matter." Küss[71] observes that it is impossible to say positively what is their exact structure, but that they have a granular surface, and "a peculiar silvery white appearance." And he, with all other observers, agrees in the existence of their nuclei. Dr. Richardson's[72] researches into their microscopic structure are the most complete of any on record, and he considers them as composed of a cell with nuclei, having amœboid movements, insoluble in water. The cell-wall is a membranous envelope, insoluble in water, and too thin to exhibit a double contour line with 1,200 diameters. Its exterior is adhesive, so that surfaces coming in contact are liable to become attached. The nuclei are sometimes not to be distinguished without the aid of acetic acid and water.

The question now naturally arises, that if these morphological constituents of the blood have elicited so much study and controversy, so much investigation, and withal are so important in the economy, what is their origin, their mode of development, of evolution? what is their relation to one another? what bearing do they have on other organs of the body, and what is their significance in pathological processes and morbid conditions? In all vertebrates, two sets of corpuscles are developed at different periods of life: a first set exists until the lymph and chyle-corpuscles appear; a second, which are developed from the last two. The former are simply the embryonic red corpuscles. Now, in order to comprehend the origin of these cells in the embryo, we may first state the outlines of embryology. By the process of segmentation the blastoderm is formed which represents the germ of the future being. Its two or three layers each give rise to distinct tissues and parts of the body. They are the epiblast, the mesoblast, and hypoblast. The mesoblast, with which we are concerned, gives origin to the connective-tissue group, the muscles, lymphatic and vascular systems, and their accessories—hence the blood. The corpuscles and vessels are formed in the germinal area, the area vasculosa, of the mesoblast—the first ones arising from a metamorphosis of mesoblastic cells in the area vasculosa. These, termed "embryonic red corpuscles," are plain, spherical masses of protoplasm, containing a nucleus. They are slightly larger than those of adult life, and appear at the same time as the vessels and heart. The cells of the mesoblast, from which these are developed, are called "embryonic cells," and are granular and spherical. From them the most widely differentiated tissues are developed. Each one appears to have its peculiar mode of expression of vitality impressed upon it, and hence some go to form connective tissue, and others the embryonic nucleated red corpuscle. In their development into the latter they become clearer, and are slightly tinged with hæmoglobin. At the same time that this formation is occurring, lymph-corpuscles are pouring into the circulation from the lymphatic glands. As seen by Remak in the embryo fowl, the nucleated red multiply partly by division. Kölliker noticed the same thing in the mammal (the rabbit); so did Frey and Paget.[73] When, in the development of the embryo, the lymph-corpuscles appear and are added to the blood, they supersede the embryo-corpuscles; and it is noticeable that this occurs in the frog at the time of the disappearance of the external branchial, and in the chick by the closure of the visceral branchial clefts.[74] Kölliker, confirmed by Weber,[75] asserts that this transformation into red nucleated cells can occur in very early fœtal life throughout the entire circulation, but, of course, ceases when the true white corpuscles and the non-nucleated red ones appear. The nucleated red are lost sight of about the third to fifth month of fœtal life in man, though the exact time is not definitely known.

Thus, it is evident that there are two sets of red corpuscles in man and mammalia—a temporary embryonic set, which are globular and have nuclei, and a permanent mature set devoid of nuclei. but biconcave. The former, being slightly larger and less red than the latter, the blood is hence paler in the embryo or fœtus than after birth, a fact observed by Glisson and Needham,[76] 1667, though the claim has been given to Coste and Delpeche.[77] Besides these red, we have also the common white corpuscles. Hence, it seems evident to us that we cannot but be prepared to recognize the embryonic set of red corpuscles of mammalia as the analogues of the mature set of red corpuscles of oviparous vertebrates, while the colorless or primogenial corpuscles are analogous to the pale globules of the blood of adult vertebrates, and to the prevailing or characteristic corpuscles of the blood of many invertebrates. This sustains the fact of a temporary structure (red nucleated embryo corpuscle) in the mammalia, corresponding to a permanent one in the ovipara; so that, in its course toward the highest type, there are temporary phases in which the blood of the mammal is analogous to the permanent state of the blood of oviparous vertebrates and of invertebrate animals.

So much for the corpuscles of the embryo, but we have yet to show the origin of the white corpuscles, a task which is not easy to do satisfactorily. That they are found in large numbers in the lymphatic glands and spleen is undeniable. The fact that in the follicles of these organs corpuscles similar, if not identical with white corpuscles, are to be found, suggests these organs as their birthplace. That they are taken up by the blood as it circulates through these is certain, as proven by the researches of Goodsir, Frey, and His, on analyses of the afferent and efferent blood. Küss, Dalton, Flint, Carpenter, and Forster all agree that they originate in the lymphatic glands, and are subsequently detached from them and find their way via the thoracic duct into the blood. It even is probable that the connective tissue of the whole body is subservient to their formation, as has been shown by Schaeffer in the rat,[78] and we can suppose any proliferating tissue[79] (Klein) to give rise to them. It has long ago been admitted that the liver is a centre for their formation, and more recently the same function has been claimed for the muscles. That the liver was regarded as an organ for their production is to be explained by the fact that more white corpuscles in comparison to the red are found in the hepatic than in the portal veins. It only shows, not that they are formed there, but that the red ones are there destroyed and produce the coloring matter of the bile. Whether they originate from pre-existing cells of like nature, or from the lymph *de novo*, we do not know. Klein saw some formed by fission and germination of white cells. That they do not immediately arise in the blood is known, because a free formation of cells does not take place anywhere. Those which he saw dividing probably were from the epithelium of the blood-vessels. Hence, their source must be sought for in the lymphatics and spleen. Having stated the birthplace of the white corpuscles, it remains for us to show their rôle, their value, their function, and use in the economy. They are, we believe, especially devoted to the production of the red corpuscles, and this opinion prevails at the present time. Flint,[80] however, thinks it right to consider that the latter originate independently of the former by a true genesis in the sanguineous blastema. His chief objection to our view is, he says, "that the red corpuscles originate before the white ones, hence they are not developed from them.

But he forgets that the fœtal red ones are formed from the embryonic corpuscles, and that they subsequently disappear to give place to the permanent non-nucleated red ones which appear at the time that lymph-corpuscles are first formed, hence at the time that the white corpuscle is changed into the red. And as they increase, the embryonic red disappear until none remain but the mature, permanent white and red. Küss[81] likewise asserts that their purpose is "to form the red ones." So also Paget,[82] who believed them to be transformed direct into the colored corpuscles, and Gulliver,[83] the English zoölogist, held the same idea. They are, "we may rightly say," observes Frey,[84] "cells which are destined to become red corpuscles." "The colorless serve to replace the red ones." This point was confirmed by Von Recklinghausen's experiments, in which he was able to change, or rather see the change of white corpuscles into the red. The blood used was that of a frog; it was kept in a vessel to prevent evaporation, the air around it was renewed once a day, and in twenty-one days he observed the change above mentioned.[85] Kirke[86] and Foster endorse the same views. Still we are in the dark as to how the change occurred, nor were we better enlightened until Neumann's discovery as to the region of the body in which it happened. In the first place, the embryonal development of the blood, as we have given above, was regarded as the key to the mystery. There we have shown that the red corpuscle in the embryo is developed from the white through the intermediate form of a colored nucleated cell, and it was hence assumed to take place in the adult body. Nor was the hypothesis an unwarranted one, because nucleated red corpuscles had been observed by Wharton Jones,[87] Busk,[88] and by Huxley in a vigorous young man; and Küss[89] states that "intermediate forms between these two kinds in respect to color and form are occasionally found." Since, however, this intermediate cell could not always be obtained, it was held by one faction (Kölliker) that they probably existed in some part of the body not yet examined; another gave up this idea and considered the red corpuscles to be the free nuclei of the white ones. Gulliver[90] first advanced this theory, which was further elaborated by Wharton Jones,[91] and Bennett[92] went so far as to say that the red cells were formed in the lymphatic glands and were only stained when they reached the blood-current. Müller believed them to arise by a fusion of the nucleus, and Funke and Zimmerman held to an endogenous method of production. As none of these views could be satisfactorily sustained, they have been relinquished; and because of the fact that in the spleen-pulp small nucleated colored corpuscles have been found similar to those in the embryo, transitional forms, showing the presence of hæmoglobin with degeneration of the nucleus, together with data above stated, justify us in regarding the red corpuscle to take origin from the white nucleated cell of the blood. In the case of animals with nucleated red corpuscles the change consists in a transformation of the protoplasm of the white cell into hæmoglobin and a stroma in which it is contained. In mammalia whose red corpuscles are without a nucleus, most observers, Kölliker,[93] Schmidt,[94] Neumann,[95] Forster,[96] agree that the nucleus of the white disappears, so that the red represents only the modified cell-structure of its progenitor, being red, denser, smaller, without a nucleus. The same diversity of opinion has existed with reference to the death-place of the red corpuscles; but if we bear in mind that the number of them in the blood varies continually, that the coloring matter of the bile and urine are derivatives of hemoglobin, it follows that an immense number of corpuscles must be destroyed in order to give rise to the amount of bile and urinary pigment daily discharged. And where most obviously would this destruction occur? Would it happen in the spleen, which has no connection with the urinary or biliary secretions, no duct? The finding of large quantities of coloring matter in the latter organ is no proof that they die there, and the abundance of lymphatic gland-tissue in it destined to produce white corpuscles renders it inconsistent to ascribe to the same organ two diametrically opposite functions. No, it is in the liver that the destruction takes place, proven by its glandular structure, by the power of the bile acids to dissolve red corpuscles, and by the analyses of the blood of the portal and hepatic veins; for Bernard, Lehman and McDonnell[97] ascertained that in blood taken from the latter the white cells were five to ten times more numerous than in blood from the former; while Hirst[98] estimated the proportion of white to red corpuscles in the portal blood to be 1 to 524, but in the hepatic as 1 to 136; and Murchison[99] also has shown the blood emerging from the liver as denser and far richer in white corpuscles than that going to it. It has however, always been a matter of the greatest difficulty to determine where the metamorphosis of the white into red corpuscles occurs. Some, on account of the transition-forms found in the spleen, have referred it to that organ. Others have delegated it to the liver, basing their judgment on the resistance the red cells of the hepatic veins, as a proof of their youth, offer to the imbibition of water; also that many red cells in the portal vein are crenated and withered, whereas those of the hepatic veins are never so.[100] These facts, if they prove anything, tend to show that the corpuscles of the portal vein are worn out, rather than that those in the hepatic veins are new; and we have no proof whatever that any new corpuscles are formed in the liver.

The exposé we have thus far given will show that in reference to the adult organism we have at present no positive testimony concerning the development of the blood-corpuscles. Even the most cogent arguments that we have enumerated, and the conclusions deduced, namely, that the white corpuscles arise in the spleen and lymphatics, that they come from the lymph, and may occasionally be formed in proliferating connective tissue, have met with some opposition; and the further ideas relative to the transformation of these white into red ones are not universally adopted, and the controversy referring to the mode of this transformation, its seat, and the fate of the red corpuscles, has been excited, often belligerent, with no evident conclusion on either side. To Neumann,[101] of Königsberg, belongs the credit of having thrown light upon the subject, and also of having inaugurated investigations which have proved of direct benefit to our knowledge of disease. He claimed the marrow of the bones to be an organ involved in the formation of blood-cells. Following him we have had Bizzozero,[102] Eales,[103] Hand,[104] Mosler,[105] and Osler.[106]

Many might be inclined to smile at the idea; but we must recollect that years ago Kölliker had expressed the opinion that the origin of the red blood-cells from the white in the adult would never be demonstrated until nucleated colored corpuscles could be discovered (which Neumann and others have done), and Henle had stated that the blood-changes would probably be found in some structure to which such a function had never been ascribed—no, not even suspected; and such is the bone-marrow. This bone-marrow, until the time of Neumann and Bizzozero, was considered simply to afford a light packing for the bones, and in some unknown manner to be connected with its vitality. Trojas[107] was the first to lay the foundation concerning this latter fact. His experiments were repeated by Koeler and by Cruveilhier,[108] with the same result. These investigations were followed by those of Ribes,[109] Reynaud,[110] Miescher,[111] Porter,[112] Boyer,[113] and Stanley,[114] but they were mostly directed to osteomyelitis. So was it with these of Gerdy,[115] Chassaignac,[116] and Dennie,[117], nothing being positively said about its structure. This was first clearly described by Robin,[118] who believed the structure of bone-marrow consisted simply of a juxtaposition of cells with the interposition of a small quantity of amorphous matter, the proportion of which varied in the different kinds of marrow. Capillary vessels are in this tissue, their meshes being twice the diameter of the capillary vessels around them. The meshes have rounded angles, and are polygonal in shape. They are more numerous next to the bone than at the other parts of the tissue. The finest capillaries found in the marrow he stated to have this peculiarity, that they are larger than the ultimate capillaries of the periosteal and osseous network. In the spongy tissue they were not cylindrical, but seemed like sinuses, and the marrow was in immediate contact with the bone. Here and there in the marrow were found fine laminated fibres in wavy bundles. From these radiated in various and very elegant arrangement fibres, medullary cells, amorphous matter, and capillaries. The fœtal or red marrow, he stated, owed its color to the abundance of medullary cells. It is the accumulation of these cells with capillary vessels and a little amorphous matter that he thought formed the red marrow. This, little by little, passes through phases of development, and is replaced by a grayish, semi-transparent, gelatinous marrow. The change in color was supposed to be due to an increase in the amorphous matter between the medullary cells, so that in this marrow he found the medullary cells more or less separated by amorphous matter, which is homogeneous, semi-transparent, and of a gelatinous appearance. The "gelatinous marrow," as he termed it, had sometimes a grayish, sometimes a yellowish color. When the former, it was said to be due to the absence of fat-cells between the other elements; and when the latter, it was caused by the medullary cells having fat ones between them. In the "fatty marrow" the vascularity was considerably less than in the "gelatinous" or "red" varieties. Now it is the "red marrow," which is found so abundantly in young subjects, and in the flat and short, and epiphyses of the long bones, that we wish to show to be the blood-producing organ in question.

The first thing noticed by Neumann and Bizzozero was that certain cells in the marrow presented amœboid movements like white corpuscles. These had been seen also by Robin, who had termed them "medullo-cells." Eales likewise described them, and we have repeatedly noted them. They are numerous, and in structure appear to be identical with "leucocytes." Besides these there were noticed other cells structurally like white blood-corpuscles, but having a distinct yellow or red tinge and a nucleus—in short, characters which to us, as well as to Neumann, Bizzozero, Eales, and Hand, seem to place them as transition types between the white and red corpuscles. The peculiarities of these tinged ones are not constant; some appear larger, others smaller; some lighter, others darker; their shape and elasticity also vary. It is on account of this variation that we find a grade of transitional cells from the regular white corpuscle to the nucleated red, on the one hand, and from it to the non-nucleated or mature colored corpuscle of the blood, on the other.

The detailed observations of the marrow of the bones of a cat, as observed by ourselves, and of the marrow in rabbits, as described by Neumann and afterward confirmed by Eales, are essentially the same, and resemble closely those which we have above stated as explained by Robin. In some points we differ; thus, for the simple juxtaposition of medullo-cells that Robin mentions, Neumann proposes the term "medullary tissue," and the nomenclature is good. The capillary network is very close, and the capillaries, as Robin demonstrated, are numerous and large, the meshes being smaller than the capillaries. In fact, the marrow arteries are also smaller than the capillaries in which they terminate. Each artery speedily divides into a bundle of capillaries like a funnel. This arrangement necessarily slackens the current, and hence there occurs an accumulation of cells in those vessels. The tissue contained in the meshes of the vascular network is composed of stellate cells "myéloplaxes" of Robin,[118] thus forming a reticulum, within which are contained in the "red marrow" a large number of "lymphoid" cells, but which are absent in the other marrows. To this red form Neumann applied the term "lymphoid medullary tissue." It is identical to us with the tissue described by Kölliker as cytogenous connective tissue, and later by His as adenoid tissue, and which we find is the essential structure in the lymphatic glands. The "yellow marrow," as Robin asserted, we still find to be without any of these lymphoid cells, but composed simply of its anastomosing cells, the contents of which are fat, and it, to all appearances, looks like simple adipose tissue. The "gelatinous medulla" differs from the red by the abundance of its intercellular substance and by the absence of the "lymphoid cells," whose place is taken up by amorphous matter.

We have thus shown that in the red marrow of the bones we have a tissue abundant in "lymphoid" elements, and resembling, if not identical with "adenoid" tissue, the tissue constituting the lymphatics and the spleen; second, that in the meshes of this tissue there is abundance of capillaries, the peculiarity of which is that their calibre is considerably larger than the arteries immediately supplying them; third, that in these meshes and their capillaries we find "medullo-cells," "lymphoid cells," resembling the white blood-corpuscles, transitional cells which are red and nucleated, true red blood-corpuscles non-nucleated, and between these extremes all shades of transition. Now, with these data, the question at once arises: What is the connection between them? Are the "lymphoid" cells in the blood derived from those in the "medullary tissue," or are the ones in the latter derived from those in the blood? We cannot but believe that the former opinion is the correct one; not that we would wish to assert that all the white blood-corpuscles are formed from the "medullary tissue," but that it takes part in their production, the same as we have shown to be the case with the lymphatic glands and the spleen. These cells find their way into the blood-current by a process of immigration, in a manner the same as in inflammation they find their way out. On casual observation it may be advanced in that case we have the force of the blood-current against us, whereas in the latter the blood-pressure favors the passage of the cells. This, however, is not so; for in the medullary tissue the current is slackened by the widening of the capillaries, which gives time for the "medullo-lymphoid cells" by their amœboid movements to get into the circulation of the medullary vessels, where we find them in great abundance. The idea of an emigration of white cells from the blood into the spaces of the reticulated medullary tissue is absurd, when we think and try to imagine what value they would be to the medulla, what would become of them; their return to the capillaries being improbable, their exit through the delicate lymphatics of the bone being equally so, and more decidedly the hard shell of bone which encloses the tissue of the medulla being especially unfavorable for any such emigration; besides, as shown by

---

[118] Diction. des méd.: E. Littré et Ch. Robin. Paris, 1873.

Kölliker, the "myéloplaxes" arise from a proliferation of the smaller "medullary cells," divide again and form a large number of smaller cells, thus demonstrating the bone-marrow to be a seat of great cell-production. If now we add to these the fact that the nutritive changes in so stable a substance as bone being far too small to need so copious a supply of organizable material, we are at once led to believe that the passage of the "lymphoid cells" into the blood-current is inevitable, in virtue of which the medulla of bone acquires an importance with regard to the formation of white blood-corpuscles equal, if not greater than, that of the spleen and lymphatics. But what value is to be placed on the nucleated red cell which we have found here, and which also exists in the embryo, and there acts as a transitional stage of development of the white into the red corpuscle. Is it to be regarded as we find it in the red marrow of bones, as a stage in the transformation of the colorless nucleated into the colored non-nucleated blood-cell?

If it be acknowledged, in accordance with the data given, that the red corpuscles do originate from the white, and that the finding of a red nucleated cell in the adult identical with that seen in the lower vertebrates and in the embryo would place the question beyond dispute, then indeed is the task accomplished. The "variation forms" between the "lymphoid" or white corpuscle, and the nucleated red cell, and of it and the non-nucleated, constitute a series "forming a perfect chain of connection," as Neumann remarks, "without any important break, from the white to the red cells," or, "at least hardly admitting of any other equally satisfactory interpretation," a series the members of which are only comprehensible when viewed as a whole. This series has been variously stated by different observers: Neumann and Eales believed it to consist of nine transitions; Bizzozero of four; but to us five stages will explain all the transformations. We might here state that we used a cat, and the mode of experimentation was to take a rib, a vertebra, or the head of a long bone, cut off a piece, and squeeze it in a vise, which causes a thick red juice to exude, which is put on a slide covered with a glass, and examined by a microscope.

The "transitions" were:

1. "Lymphoid medullary cells," analogous to white blood-corpuscles, granular, of a fatty lustre, sometimes with or without a nucleus.
2. Cells essentially the same, slightly colored, but always with a large "granular nucleus."
3. Red nucleated cells, like those of the embryo.
4. Red cells with a nucleus in a state of granulation.
5. Non-nucleated red corpuscles.

With these cells squeezed out, other elements can be seen, as amorphous matter, the larger medullary or connective tissue, "myéloplaxes," and débris. Now, shall we regard such a series as a mere coincidence, mere accidental phenomena, or rather as expressions, as "equivalents," of the mode of development, of evolution of the most vitalized tissue of the economy—the blood? True it is that we might theoretically expect variations in the corpuscles of the blood (and such is the case within certain limits), when we consider how thin, pliant, and elastic they are; how they must be constantly taking in or giving out fluid, according to their relation in density with that of the blood-plasma. One may see them flat or tumid, cup-like or stellate, notched or corrugated; hence persons, when they have observed these cells in healthy or morbid conditions, often think they have discovered something wonderful or pathognomonic of diseased states, whereas these "unique forms," so to speak, are but accidental variations due to temporary surroundings. Not so with those cells seen in the bone marrow; their transitions are peculiarities of structure, not of form; those are constant, and graded to one another, indicating logical sequence; these temporary, accidental, without morphological relation, the result of evanescent circumstances which have influenced the blood in which they circulate. It is hence that we ask, shall we not consider that a transformation of the "medulla" or "lymphoid" cells, or white blood-corpuscles, which you please, that have been shown to be produced in the red marrow of bones, and to accumulate in its blood-vessels—shall we not consider, we ask—that they are transformed, "metamorphosed" into the red nucleated cells, and thence into the mature non-nucleated red blood-corpuscle? True it is that the origin, development, and evolution of the cellular elements of the blood is one of the least understood of physiological processes; true it is that numerous and varied observations, facts, opinions, and theories, have been maintained regarding the blood-corpuscles, the transformation of the white into the red, and the ultimate fate of the latter; true it is that these have been successively discarded, and have given place to some new speculation, which has, in its turn, shared the fate of its predecessors; so that we might be tempted to consider the whole as a mass of ideas incapable of any systematic or logical sequence, from which it was impossible to deduce any generalized principles. But we think the researches of Neumann and Bizzozero, Eales, Hand, and ourselves establish the fact that the marrow of bones contains colorless cell-elements like white blood-corpuscles, also "transition-cells," intermediate between the white and red corpuscles, being colored and nucleated, and, lastly, true red corpuscles; that it resembles and seems to be identical with the function and structure of the lymphatics and spleen; that, like the lymphatics and spleen, it has the power to produce white blood-corpuscles, but, unlike the lymphatics, yet like the spleen, it has also the function to transform the white into the red corpuscle of the blood; so that it cannot be doubted but that it belongs to the class of hematopoietic or blood-forming organs of the body.

The process of transformation of the "lymphoid-cells" of the medulla, or of the white blood-corpuscles into red ones, appears to us, judging from the intermediate forms seen in the spleen and in the red marrow of bones to be as follows: the granulations in the "medullary lymphoid-cells" (analogous to white blood-corpuscles), diminish from the periphery, and seem to collect more or less about the central nucleus, and thus produce the cell with a large "granulated nucleus;" at the same time the rest of the cell becomes tinged reddish, and we have formed the "transitional" nucleated red blood-corpuscle. Now, as to the manner in which this latter becomes a non-nucleated one opinions still differ, and various explanations are advanced by the different observers. Bizzozero and Hand hold that it is the freed nucleus of the former; that the granulations of the nucleated red "transitional" cell disappear, and the nucleus is liberated to increase in size and form the red corpuscle.

With this opinion we do not agree; rather do we believe the red "transitional" form to be changed in its entirety into the red; that the "lymphoid cell" or white corpuscle gives origin to the red by a transformation of its entire structure. They do not differ from us as to the fact that the red cells are transformed from the white in the bone marrow, but only as to its method. Our reasons for believing that the change is entire rather than partial in structure are: 1st, no one has ever seen the rupture of the enclosing cell-wall of the "transition" form that must occur if the latter be true, and in the event of it not occurring, the endogenous method is fallacious; 2d, in her modes of development, nature always adheres to fixed laws alike for all homologous and analogous conditions. Her principle in the evolution of a specialized "expression" out of a generalized one is not that when the former appears there is a consentaneous disappearance of the latter, but that it remains and is only modified by its more highly developed constituent. Thus, in the plant a pistil or stamen is but a specialized petal, and the petal but a modified sepal, and the latter simply a more highly developed leaf, the leaf expression or power being in them all, as is well seen in cases of reversion, not discarded when specialization occurs. So also in the ovule, with its vitelline membrane and vitellus, its germinal area and germinal spot; specialization occurs as demonstrated by the disappearance of the nucleus, and the formation by segmentation of the mulberry mass; yet here the vitelline membrane is visible and the original appearance of the generalized body remains. Likewise, in the transformation of the red nucleated cell into the red non-nucleated one, there is no necessity to consider a rupture of the wall and the escape of a nucleus; rather let us believe that the nucleus disappears by specialization, and imparts its own inherent vitality to the new red blood-corpuscle, by virtue of which it is distinguished in its functions from the white corpuscle and its transitional forms. Were there no confirmatory proofs, we might not be so confident as to the agency of the bone-marrow as a blood-forming organ in the economy, since other interpretations might be made of the cells in question. But when we direct our attention to the changes induced in the marrow by pathological influences, then, indeed, do our opinions become more convincing. Thus, in leucocythæmia, the honor of whose discovery is divided between Bennett and Virchow,[119] is its value clearly defined. Suffice it to say that in this disease we have anæmia, lymphatic, splenic, and medullary enlargement (hyperplasia), and an enormous increase in the white corpuscles of the blood. Now, what is the anæmia, the great abundance of white cells, due to? The spleen and lymphatics being enlarged, naturally we have an explanation. In health, these organs producing white and red corpuscles through disease, have taken on an increased activity, and augmented the number of cells. But Neumann, with a mind full with the importance of his discovery, intuitively saw that if it had any value now was the time to prove it. Hence, observations in the post-mortem room directed to bone-marrow reaped a harvest. Here was noticed, in the medulla of bones of leucocythemia, an enormous increase in the medullary tissue; here was seen vast quantities of lymphoid cells, of developmental forms of red corpuscle, and here naturally arose a factor in the pathology of this interesting disease. If, then, we have an exaltation of the normal functions of the lymphatics and spleen in leucocythemia, and if, as proven by observations of Neumann, Huber, Waldeyer, Wood, Ponfick, and Pepper, no cases of it have as yet been described in which, on examination, the marrow has been found normal, then there can be no objection to the view that the disease is constantly associated with a pathological alteration of the marrow, an alteration which is essentially a sort of compensatory activity of its physiological hematopoietic function, a hyperplasia, a simple increase in its normal powers and functions.[120]

326 South Twelfth Street, Philadelphia.

SIMPLE DILATATION OF THE STOMACH.

By HORATIO R. BIGELOW, M.D.,

WASHINGTON, D.C.

Six months ago I was called to see a colored woman, Mrs. H——, who presented the following symptoms: The patient is fifty years of age, having passed the climacteric period. The face is pinched, wrinkled, and parchment-like, and bears the anxious expression incident to a chronic disease. She has no well-defined pain, but a gnawing, indescribable uneasiness in the stomach. There is increasing and general emaciation. The appetite is excessive, but she has a dread of satisfying it, as every meal is followed by eructations and meteorism, which are succeeded by vomiting. There is marked constipation, with alkaline urine, and the vomited matter contains sarcinæ. She has pains and muscular cramps in different regions of the body. The integument covering the abdomen is wrinkled and thrown into folds, so that the peristalsis can be made out in the sunken fossæ by palpation. The colon is depressed into the hypogastrium. When the patient is turned suddenly on her side, or when the abdomen is shaken, the *splashing* is very audible. The sound passed beyond the teeth, can be felt on a level with the umbilicus. The diagnosis was arrived at with no little difficulty. The patient had suffered in previous years with febrile disorders, but the abdominal symptoms became appreciable about three months only before she sent for me. Constriction of the pylorus, cancer, and ulceration, as well as peritonitis with inflammatory adhesions—the frequent causes of dilated stomach—were excluded, as presenting no characteristic phenomena. From her description I was led to infer that the patient had suffered primarily with catarrh of the stomach, and that this condition had set up a chronic *hypertrophy* of the muscular coat of that viscus. There was no reason to suspect pyloric constriction; the history of the case seemed to point to an opposite condition of enlargement. The catarrh had been unattended with excessive vomiting, and she had never seen any blood in the matter so rejected. There was no well-defined, localized pain. If this *was* a case of simple, uncomplicated dilatation, how had it been caused? Here we have a nice problem, worthy of consideration. The literature upon this subject shows that cases of uncomplicated dilation are exceedingly rare—so rare, indeed, that the possibility of its existence is denied by a few of those who have written upon the matter. So far as my memory serves me, I do not now remember that any instances of dilation in which some well-defined aggressive factor was not also present are alluded to by Penzoldt, Leube, or Kussmaul, although Dr. T. Clifford Allbutt, in the *British Medical Journal* of February 28, 1880, gives it as his opinion that it may not only be possible, but is not as uncommon as the profession generally suppose. He writes as follows: "The chief cause of a dilated stomach is, no doubt, obstruction forward—a thickening of the pylorus by cancer, cicatrix, or otherwise; and, as in the cases of the heart and bladder, the relation of hypertrophy to distention depends on the health of the individual and on the gradual advance of the obstruction. In simple dilatation of the stomach the cause is not found in pyloric obstruction, the pylorus being often itself dilated. The causes lie in the stomach itself. In those cases in which the muscular coat is atrophied, the sac gives way perhaps from its own inability to resist ordinary strain. Such cases are certainly a small minority of those recorded in the post-mortem room; but I believe the condition to be a common one in patients debilitated by prolonged disease, and especially by febrile disease." "Leube, in his section on this malady, in Ziemssen's 'Handbuch,' vol. vii., part 2, 1876, states that the malady was recognized, among others, by Spigelius in 1623, by Van Swieten in 1754, by Sauvages in 1768, by Morgan in 1774, and in our own time by Oppolzer and Traube, by Kussmaul and Penzoldt." Finally, Dr. Allbutt writes: "I have had but two opportunities of seeing on the post-mortem tables specimens of dilated stomach, apart, that is, from causation by mechanical obstruction. In both cases the stomach was enormously enlarged, and, indeed, on section of the abdominal wall, was seen to occupy the whole of the anterior portion of the abdominal cavity. I have not measured the cubic contents of such a stomach. The pylorus and duodenum in these two cases were also dilated. Neighboring organs were thrust into the rear, and the bowels were nearly empty. The coats of the stomach, when cut into, were seen to be thickened chiefly, it would seem, by development of the muscular coat. The mucous membrane was smooth and thin, but I have no notes of its structure.

Med., 13th July, 1878; Cincinnati Lancet, Aug. 31, 1878; Comptes rendus, 1869, p. 1112; Biennial Retrospect. 1868; Centralblatt. 1868, p. 689; Archiv der Heilkunde, 1869, x., p. 68; Bizzozero: Gaz. Med. Ital. Lomb., 1869, p. 2; Mosler: Virchow Archiv. 1873, p. 532; Phila. Med. Times, 1872, Nov. 15th; Hüber: Deutsches Archiv für klin. Med., 12. 1873, p. 389; Wood: Phila. Med. Times, 1874, p. 215; Schmuzzer: Archiv der Heilk., 1876, 17, p. 273; Tyson: Path. Soc. Phila., 1876, April 27; Mosler: Berlin. klin. Woch., Dec., 1876; Kelsch: Brown-Sequard's Archiv. ii. s., tome ii., p. 492; London Record. 1877, p. 157; Osler: London Lancet, 1878, p. 162; Janeway: New York Med. Record, 1876, p. 275; Wilks: London Record, 1861, p. 9; Da Costa: Amer. Journ. Med. Sci., 1875, p. 121; Biesadecki: London Times, 1872, p. 552; Chvostek: London Record, 1877, p. 274; Jaccoud: Leçons de clin. méd., 1873; London Times, 1877, p. 679.

The enlargement of the cavity was uniform in both cases, the larger curvature reaching into the hypogastrium. Indeed, to my eye these stomachs differed but little, if at all, from those in which dilatation had been caused by pyloric obstruction. The more careful necropsies of other writers speak of a general thinning of all the coats of the organ (Penzoldt) in a minority of cases, which are to be contrasted with those other published cases in which the walls of the stomach have seemed, by great hypertrophy, to have resisted dilatation, in which, indeed, an enormous hypertrophy of the muscular coat has actually diminished the cavity of the organ. Commonly it is found that although the stomach be greatly enlarged, yet the muscular coat is not atrophied, but decidedly hypertrophied; and, moreover, that the intimate structure of the muscular coat is not degraded. . . . . The only other detail now to be noticed in these necropsies is the position of the colon, which, in well-marked cases, occupies the lower hypogastrium, or may be overlaid by the stomach." The conclusion that I reached, after a study of the bibliography of the subject, together with a knowledge of the peculiar habits of the colored race, was that a condition of catarrh had been inaugurated through the constant ingestion of the most indigestible food, such as is the daily diet of negroes; that, through a lack of peptic power, the food was unassimilated. Gradually the coats of the stomach began to distend, so that its cavity might accommodate the increasing amount of food taken in, and that this condition obtained through enormous hypertrophy of the muscular coat. Upon this assumption, I first placed my patient upon daily doses of carbolic acid, followed by nitrate of silver and bismuth, feeding her by the rectum; but, as no benefit ensued, I resorted to the plan suggested by Prof. Kussmaul (Archiv. für klinische Medicin, 1869) of washing out the stomach with tepid water. It was a nasty process for practitioner and patient; the more so as I was obliged to use a stomach-pump, having no syphon, as recommended by Dr. Allbutt. The relief was immediate and permanent, and its efficiency was enhanced by the use of lactopeptine. The success which attends this method of procedure in simple dilatation would probably be equally great in dilatations depending upon any mechanical obstruction. The difficulty in diagnosis is not one of fact, but one of kind. The increasing bulk of the stomach may be made out with comparative ease, but the causation of the dilation is a question attended with much embarrassment. Generally, however, it may be said that in pyloric constriction from any cause whatsoever, we will have certain definite signs to guide us, which are absent in cases of simple dilatation. In the early stages of the malady much difficulty will be experienced in formulating a diagnosis.

A CASE OF

POISONING WITH HOMŒOPATHIC GRANULES OF "NUX."

By GASPAR GRISWOLD, M.D.,

NEW YORK.

On the fourteenth of August I was suddenly called to attend a lady who, I was told, had just had a stroke of paralysis. I found a young woman lying upon a bed, where she had been laid fainting a few minutes before. She had regained consciousness as I entered the room, and was much alarmed, complaining that she had suddenly lost all power over her hands and feet, and was unable to move them. Her fingers were extended, and she could not flex them; close inspection detected almost continuous twitchings of the small muscles of the hand. The condition was evidently one of tonic spasm, and not of paralysis. The face was pale, and the pupils were equal and widely dilated; the patient complained that she could not see distinctly, and that everything looked far away and blurred. The respirations, although disturbed in rhythm by nervousness and excitement, were, nevertheless, evidently efficient; a moment's auscultation showed the heart beating clearly and forcibly about 100 times per minute. The patient's mind was even abnormally sensitive, and she, herself, keenly apprehensive; despite her alarm, natural under the circumstances, there was a certain dignity and apparent effort to keep calm—an absence of the dramatic element in her manner, which silenced any suspicion of hysteria which might have been suggested by symptoms somewhat difficult to account for in any other way under the circumstances. In addition to this, the dilatation of the pupils was so conspicuous as to call for some other explanation. The mental clearness, associated with marked disturbance of the functions of the spinal cord, at once suggested strychnia, and I asked if she had not taken something—a medicine for her eyes, the last teaspoonful of a tonic mixture, etc. The members of the family denied that she had taken any medicine for a long while, and, being wedded to the opinion that the trouble was paralysis (of which they said many of their relatives had died), almost resented my persisting in asking questions. Suddenly the patient herself remembered that she had taken some homœopathic granules which she had long been in the habit of prescribing for herself when threatened with a sick headache. The dose had originally been five granules, taken two or three times; but that morning, feeling very badly, and fearing that the medicine might have lost its strength by having been kept for a year or so, she increased the dose to fourteen granules, and took it five times—*seventy granules in all, in the course of an hour and a half.* This occurred about an hour before the alarming symptoms presented themselves; she had for the time forgotten that she had taken the medicine, not dreaming that it was the cause of her sickness, and, indeed, considering that "homœopathic medicine was in any case harmless, since it affected merely the disease, and not the patient." The vial of granules was given me, and on the cork I read "Nux." During the few minutes required for diagnosis, the symptoms became more marked; a slight convulsion occurrēd, with suspension of respiration and a suggestion of opisthotonos. The face became deathly pale, the pupils even more widely dilated, and the patient fainted—apparently from cerebral anæmia. The inhalation of a few drops of nitrite of amyl (a bottle of which I was fortunate enough to have with me) rapidly restored her. Some chloroform was obtained just in time to be administered during a second convulsion, which was a little more marked than the first had been; two drachms of bromide of potassium were given as soon as the patient was able to swallow. The room was darkened and kept quiet, and slight inhalations of chloroform were continued for about twenty minutes, until the bromide of potassium could be absorbed and produce its effects. No further convulsions occurred; in an hour the danger had passed, and very soon afterward the symptoms had all disappeared. I have been unable to discover the strength of the granules; they were obtained while the patient was travelling in the west, and the circumstances attending their purchase have been forgotten. One of them, which I allowed to dissolve in my mouth, had a distinctly bitter taste; and the symptoms above recorded undoubtedly attest the presence of a larger proportion of the original drug than is sustained by any tenet which survives the visionary Hahnemann.

◆

CHIAN TURPENTINE AND UTERINE CANCER.—The first case in this country, which we have seen reported, of the use of Chian turpentine for uterine cancer, is related by Dr. J. R. Wheat, in the *Va. Medical Monthly*. The patient, aged 39, had had symptoms of uterine cancer for about a year when she came under Dr. Wheat's care. Three-grain pills of Chian turpentine were given every four hours. No other measure was employed. At the end of a week she felt much better. Improvement was then more slow, but is still continued up to the time of report.

TREATMENT OF FETID PERSPIRATION OF THE FEET.

By F. C. AINSWORTH,

ASSISTANT SURGEON, U. S. A.

THIS form of osmidrosis, which is almost always, if not invariably in its severe forms, associated with, or an accompaniment of, local hyperidrosis, is as rebellious to the treatment prescribed by text-books and standard authorities as it is mortifying and annoying to the unfortunate sufferer and disgusting to his associates. Those cases in which the offensive odor is unaccompanied by excessive perspiration of the parts very rarely come under the notice of a physician, because they are, I believe, as a rule, the result of a want of cleanliness, and the application of a little much-needed soap and water, or at most, some of the milder measures in common use, suffice to remove the trouble.

But those aggravated cases, in which the feet are constantly bathed in moisture to such an extent that, after being worn but a few hours, the stockings are saturated and dripping when wrung, the skin white, macerated, blistered, and cracked, rendering locomotion painful in the extreme, while the disgusting odor is constantly perceptible in spite of almost hourly bathings and changes of the stockings, are but little benefited by the measures ordinarily resorted to. Lotions—aromatic, alcoholic, and astringent—are resorted to, together with all sorts of absorbent powders, with but little, if any, benefit.

Hebra's method of applying the diachylon plaster, while much more effective than the above, is disagreeable to the patient, and, to be properly carried out, requires the personal attention of the surgeon.

Several years ago I began using salicylic acid in this complaint, combined with some inert absorbent powder, but soon found that while the acid quite promptly removed the fetid smell, the excess of moisture was but little, if at all, diminished, and the case was as bad as ever soon after the discontinuance of the remedy. After a number of trials I adopted the following combination, which I have since been using with the greatest satisfaction both to myself and the patient:

℞. Pulv. alum. exsiccati........ ℥ iij.
Acid. salicylici............. ʒ jss.–iij.
M.

The patient is directed to bathe the feet every morning with warm soap and water, then to dry them gently with a towel, and, while they are yet moist enough to cause the powder to partially adhere, to apply freely the above mixture to the whole foot, taking care to leave a good quantity between the toes and in the sulcus underneath them. A quantity of the powder is dusted into the stockings, as well as into the shoes, before they are put on. At the outset it may be necessary to make this application twice, or, in rare cases, three times daily, but in a few days one application made in the morning will be sufficient. When the powder is to be used more than once daily, it is not necessary that the feet should be washed for the second or third occasion, because they are then sufficiently moist to cause the mixture to adhere, and, moreover, the same stockings which are already full of the powder should be reapplied.

Clean stockings should be used each morning, and a different pair of shoes, preferably low ones, should be worn each day.

After a few days of this treatment the skin of the feet begins to exfoliate between the toes. If the applications are continued, as they should be, the exfoliation process extends to the tough, thick skin on the sole, until finally a new and healthy layer has entirely replaced the old; then the treatment can be discontinued.

In several cases which I have treated, the trouble has partially returned after about a year, as it does after Hebra's method has been used; but it disappears after a few days' use of the alum and salicylic acid mixture.

It is desirable that the alum should be very thoroughly burned and reduced to an impalpable powder.

The patient should be cautioned to keep his head turned as much as possible during the application of the powder, as, when inhaled, the salicylic acid produces a fit of sneezing and coughing which may last for some time.

Although I have never had occasion to prescribe for other local hyperidroses, as of the axillæ or genitals, I see no reason why the above plan of treatment would not be equally beneficial in them. Of course the strength of the powder might need to be reduced so as to render its application painless, when used about the genitals.

WHIPPLE BARRACKS, A. T., 1880.

Progress of Medical Science.

NARCOLEPSY.—This name has been proposed by Dr. Gélineau to designate a rare, or, at least, hitherto imperfectly known malady, characterized by irresistible desire to sleep. (The word is derived from the Greek narkosis: somnolence, and lambanein: to seize, take.) The word also recalls the twofold analogy to somnolence and catalepsy. It is said to come on suddenly, at irregular intervals, and to last only a short time.

Gélineau succeeded in finding the record of one other case of this peculiar affection, his own observation thus being the second. The first case (*Journal de méd. mentale*, Nos. 8 and 9, 1862) was that of a large, powerful man, forty-seven years old, married, whose habits were strictly sober, and who had had no previous malady. This man was compelled to give up his employment, owing to an incessant and imperative desire to sleep. He was liable to be seized with this propensity at any time, whether walking, seated, or lying down. When he awoke he shortly fell asleep again. His face seemed pale and puffy, his attitude was one of dull indifference, his intelligence was "lazy," but his general health and embonpoint had not suffered during the four years of his sickness. Divers methods of treatment had failed to cure him.

The second case, observed by the author himself, was that of a dealer in casks, thirty-eight years of age, and of a "nervoso-sanguin" temperament. Three years ago he received a violent blow with the fist, and during the ensuing quarrel was arrested and confined in prison. This had caused him a severe chagrin. A little later, a falling log of wood struck his head, but this turned out to be but a slight accident. It was about a year after this that he first noticed a weakness in his legs. Some time afterward, when playing cards, and holding a good hand, he was unable to move his arms, his head hung down, and he fell asleep, awaking about a minute later. Soon the slightest emotion would suffice to bring on sleep, and this imperative propensity caused him considerable annoyance "His meals are disturbed again and again by this desire for repose; his eyelids droop; the hands let fall a fork, knife, or glass; the sentence which he had begun with a loud voice is completed with difficulty, and in low, stammering tones; his head sinks, he sleeps." Willed efforts were powerless to control this overpowering desire for sleep. While walking in the streets he was liable to be seized with a sleeping fit. Any profound emotion invariably produced a rapid attack. Bad weather, especially an approaching storm, increased the number of attacks, which might rise to two hundred a day. Violent shaking or pinching would, however, prevent the seizure. During sleep his pulse, ordinarily 66 or 68, falls to 58 or 60 beats per minute. The pupils, quite contracted when he is awake, are less so when he has a seizure. These last from one to five minutes.

His appearance is not one of disease; he eats well, sleeps well at night, and his bowels are regular. Urine or fæces never escape during these periods of morbid sleep. His memory has not suffered; he still attends his business affairs, but he never went out unaccompanied. Dr. Gélineau is of opinion that this malady is not epilepsy, but a hitherto undescribed neurosis, which may be called narcolepsy.—*Gaz. des hôp.*, July 8, 1880.

CASE OF PROLONGED ECLAMPSIA AND COMA IN A CHILD.—Dr. A. Kien, of Strasbourg, reported the following case to the Strasburg Medical Society: On the 24th of April he was called in great haste, to see a child that had quite suddenly fallen sick in the afternoon. When he saw the child, a little girl four years old, he found her completely comatose. He learned from its mother that the child during that day's afternoon walk with her had suddenly been bent over to one side, had then grown very pale, and had finally been seized with general convulsions. Several minutes later the paroxysm had ceased and had been followed by a condition of profound coma, from which the child had not yet been roused, despite the various efforts in that direction. Vomiting had also occurred, and the convulsions had again come on, and had been repeated about every half-hour. Dr. Kien found the girl stretched out on a bed in profound coma. The respiration was noisy and accelerated; the pulse was feeble and beat at the rate of 160 per minute; the temperature appeared normal. All the muscles were relaxed; peripheral irritation provoked no sign of sensibility or reflex action. The eyes were widely open, motionless, and with the pupils much dilated. Urine and fluid fæcal matter (the result of an injection) had been unconsciously voided. The doctor soon witnessed an attack, which he describes as possessing all the characteristic qualities of eclampsia—initial pallor, with stretching of the whole body, momentary cessation of respiration, the general clonic convulsions with foaming at the mouth, followed after about three minutes by a profound sighing respiration, and, finally, coma. The previous history gave no clue to the nature of this singular affection. The child had always been well. Accordingly, the treatment adopted was symptomatic. On the following day the child's condition remained unchanged, barring the supervention of a distinctly marked febrile movement. One day later the convulsions ceased, but the coma continued. The cessation of the convulsions had taken place immediately after a warm bath followed by a cold douche. The coma resisted all treatment, and finally, on the eighth day, warm bathing followed by the cold douche was again resorted to. After the first bath the girl regained consciousness, and called to her parents. From this time on the child rapidly improved, and is now completely cured. An occasional slight strabismus is the only residual symptom.

In discussing the probable nature of this affection the writer finally arrives at the conclusion that it must have been a case of insolation. An active cerebral congestion with subsequent œdema, or serous effusion into the meninges and cavities of the brain, he thinks, was at the bottom of the disease. For the curative action of the cold douche he is unable to offer any satisfactory explanation.—*Gazette obstétricale*, August 5, 1880.

Bromide of Ethyl in Hysteria and Epilepsy.—At a recent meeting of the Paris Biological Society, Bourneville and D'Olier reported the results of investigations carried on for the past two months, concerning the physiological action of bromide of ethyl in hysteria and epilepsy. Their observations are comprised under three headings: 1. Action on the attacks of hysteria. The medicament almost invariably brought about a cessation of convulsive phenomena, and in two patients it several times produced the rapid transition of the stage of "clownism" into the condition of delirium. 2. Action on epileptic seizures. The inhalation of the drug commenced with the inception of the period of muscular rigidity, in three cases, effected perfect relaxation after several seconds of inhalation. In other cases the severity and duration of the convulsions appeared to be diminished. In some cases the ethyl bromide seemed to produce no appreciable effect on the patients. 3. Action on epilepsy. Ten patients, of which number five were adults and five children, were for two months subjected to a daily course of inhalation continued to anæsthesia, and in some cases prolonged for twenty minutes. A considerable diminution of the number of seizures was noted in five cases. Concerning the other five no mention is made.

In five cases the writers also observed a lowering of the temperature of less than half a degree during the progress of inhalation. Immediately afterward the temperature again rose, and in some cases even exceeded the normal limits. In their five hundred observations, the authors also found, as a rule, a slight increase in the pulse-rate during inhalation. In six cases the pulse became somewhat retarded. The respiration was also somewhat increased in frequency. The lachrymal secretion became rather abundant in almost every case. The renal secretion did not appear to be influenced. Two of the ten patients observed for the last two weeks showed muscular rigidity accompanied by tremors, especially marked in the arms, at the commencement of the inhalations. The general health in no instance suffered from these experiments.—*Le Progrès médical*, August 7, 1880.

Dacryocysto-Blennorrhœa—Treatment by Scarifications of the entire Lachrymal Duct.—Prof. Schmidt-Rimpler, of Marburg, has devised a little knife intended for scarifications of the lachrymal ducts in those cases of persistent catarrh which are independent of stricture in the lachrymal passages. Still, the author adds, stricture would not be a contraindication to the use of the scarifier. In fact, he has cured or improved such cases—which refused to yield to the prolonged employment of Bowman's sounds—by means of repeated scarifications of the mucous membrane. In chronic catarrhs of the lachrymal passages the mucous membrane is found to be thickened, and it is this thickening which causes the unpleasant symptoms complained of by the patients. Now, Schmidt-Rimpler believes that scarifications relieve this thickening, partly by an immediate diminution of the engorgement of the mucous membrane, partly by subsequent cicatricial contraction. Accordingly, he advises deep scarifications of the entire naso-lachrymal duct, not incisions, confined to the lachrymal sac, as he and others had formerly recommended. Of course, when the duct does not allow the passage of his new knife, the sac alone must be thus treated; but, in most cases, the small knife can be made to enter without much difficulty. He describes two sizes of these knives. One is a probe-tipped scarifier, 2 mm. broad, with a convex blade, and 1½ ctm. long, secured to a handle by an intermediate probe, corresponding in thickness to a large Bowman's sound, and 2½ ctm. in length. The other knife is essentially the same, only much smaller. The method of employment is as follows: the direction of the naso-lachrymal duct having been ascertained, the scarifier is passed in through the superior, previously slit lachrymal canal. The instrument being held in a horizontal position, as soon as the tip reaches the nasal wall of the lachrymal sac the handle is elevated and the cutting surface directed anteriorly; it is pushed down through the entire duct. Then the knife is turned, and as the instrument is withdrawn, a second incision is made. When the lachrymal sac is reached its walls are deeply scarified. In this way all existing valves, thickenings, and diverticula are cut, as is shown by the reappearance of matter, after previous pressure had failed to yield any. Hemorrhage, says the author, is never profuse, and may be stopped by compression of the lachrymal sac. The pain of the operation is apparently no greater than that incident to the forced passage of a sound. Cold applications, followed, when necessary, by astringent washes, are the only subsequent treatment. Should previous symptoms return, the operation may be repeated and a cure finally effected.—*Berl. klin. Woch.*, July 26, 1889.

Ladies' Sanitary Towels.—At a meeting of the Obstetrical Society of London, Wednesday, July 7, 1880, Dr. Gallabin presented for examination some new sanitary towels for use during the catamenia and after confinement. They contained a pad of absorbent cotton-wool, rendered antiseptic by boracic acid, as being less irritating than other antiseptics. The advantages were that they could be burned after use, and so were especially valuable for the lying-in room, and that they were very soft and absorbent. The retail price was three shillings a dozen, and it was believed that the cost would not much exceed that of the washing of ordinary diapers, since they could be worn longer.—*British Medical Journal*, August 7, 1880.

Beri-beri in San Francisco.—Surgeon E. Hebersmith reports to the Marine Hospital Bureau that eighteen men from the Brazilian man-of-war Vitol de Oliveira were admitted into the U. S. Marine Hospital at San Francisco on the 21st of August, sixteen of whom were suffering from the rare disease known as "beri-beri," or the "bad sickness of Ceylon." Beri-beri is an Indian disease, a cachexia in which there is great muscular weakness, tremors, painful numbness, etc. It is generally curable.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, October 2, 1880.

THE MEDICAL REGISTRATION LAW.

THE law at present in force, regulating the licensing of practising physicians and surgeons in this city, is as comprehensive in its scope and as perfect in its detail as could be expected under the circumstances. Heretofore the mistake in all similar laws has been the aiming after impossibilities, and the consequence naturally has been that their provisions have been not only ignored, but the whole subject of medical legislation has been very justly brought into ridicule. The point of excellence in the law of this year is centred in the second section, which provides for a registration of all such as are or shall be legally qualified to practise medicine or surgery. Although this may have put many to an inconvenience, the latter is more than balanced by the good that must eventually accrue to each individual member of the profession. With such an end in view, the fact of compulsory registration is one with which the profession at large must be in accord. In fact, the willingness with which the great majority of medical men came forward to testify in a practical manner to the utility of the law, by complying with all its requirements, is a gratifying evidence of the truth of this assumption. From all parts of the State we hear that the legally qualified practitioners of medicine have been registering, and that the various county clerks have full lists of all medical men within their jurisdiction.

It is perhaps proper, in this connection, to call the attention of those physicians in this State, who may have neglected to register, to the fact that from the first of October they have rendered themselves liable to a fine of fifty dollars for the first offence of practising as an unregistered practitioner, and not less than one hundred dollars for each succeeding one. As one-half of such fines goes to the informer, it is easy to see that there may be peculiar inducements to some parties for making the necessary complaints. The provision of the law respecting the fines are so explicit that there does not seem to be a possibility of escaping a penalty when once its liability is proven.

There is no easier way of making a distinction between the legally qualified medical practitioner and the quack than the compulsory registration of qualifications. The qualifications fixed by law are so simple that none can misunderstand them, neither can any one complain that the standard of requirements is not within the reach of any ordinarily educated practitioner. It is this and other features of the new law which make it so consistent and so practicable. As there is now no legal excuse why even every professionally qualified medical man in this State should not be registered, there is still less to be said of such as are practising without license. To such medical men as believe that this law will be equally ineffective with previous ones, in suppressing irregular practices, we commend a careful reading of its provisions. It must be conceded that the framers of the bill understood the situation very thoroughly, and that every reasonable means have been used to prevent the illegal practice of medicine. The homœopaths and eclectics have equal rights with the regulars under the law, which is perfectly proper, and which will tend to divest the law of all supposed partisanship, and free it from all the elements of class legislation. Its whole aim is so clearly in the best interests of the people at large, that it can hardly fail to become as popular with outsiders as it already appears to be with the profession.

It remains to be seen what will be the effect of this law upon the irregular practitioners, men and women, who prescribe without any legal qualifications; clairvoyants, mesmerists, counter-prescribing druggists, and others of the same ilk. To continue their practices would be in open violation of the law, from the penalties of which there does not appear to be a reasonable escape. It is explicitly stated that no one shall practise medicine or surgery in this State, without either having received a diploma or endorsement from a legally qualified medical college of this State, or from a Board of Examiners of the State University, evidence of either of which must be given by affidavit at the time of registering. As the registration is compulsory, hardly anything more can be desired to make the law effective. There are some features of the law which will have a tendency to reach beyond the mere suppression of quackery in some of its more pronounced forms. While much authority is vested in the medical colleges for granting diplomas, the State in its turn has a right to demand that the requirements for graduation shall come up to a certain standard. Failing to do this, such colleges can be deprived of their charter. By such means can colleges be prevented from disposing of their diplomas for shorter periods of study than required by law, and the bogus diploma trade can be suppressed.

A NEW GERMAN TREATMENT FOR TYPHOID FEVER.

Every little while the medical profession is surprised with a new treatment for typhoid fever. But there does not seem to be any limit to the variety of ways in which our therapeutic forces can be marshalled against the disease. Dr. C. G. Rothe has recently presented a new method—the antiseptic—of treating typhoid fever.

The doctor had formerly treated his cases of this disease—with due respect to him—very badly indeed, from an American standpoint at least. He was accustomed to give hourly doses of infusion of digitalis, with aconite and tincture of iodine, until a distinct effect on the pulse was produced. Whether this effect was that of the digitalis, or of that of its antagonist, aconite, it is not stated. With these drugs he used frequent cold wrappings, quinine or salicylic acid in large doses; and if the temperature persisted above 104° he gave cold baths. Of six cases which he records, treated in this way, one died, and in the remainder convalescence was much protracted.

In nineteen subsequent cases Dr. Rothe adopted a new method, which he had hit upon accidentally. This consisted in giving a mixture of one or two parts of carbolic acid, and one of tincture of iodine, in 120 of water. A tablespoonful of the mixture was given every hour until a noticeable effect upon the pulse and temperature was produced. With this was combined for a time, at first, infusion or tincture of digitalis, and cold wrappings frequently renewed. All the cases recovered. Dr. Rothe states that they all came under his treatment while having high morning temperatures, and that in all alike, first the pulse and then the temperature sank within from two to seven days. The pulse frequently went below the normal, and did not rise to its former height except when the medicine was discontinued, or given less frequently, by way of experiment. The effect could not have been due to the digitalis, for this was only given for a short time at the beginning of treatment. Besides, the severe symptoms immediately reappeared if the iodine and carbolic acid were discontinued. The tongue, in the cases treated as above, never got brown and crusty; the gastric symptoms subsided very early, and a moderate appetite soon appeared.

The explanation given of the way in which the drugs produce these beneficial results is: 1st, that they act upon the vagus or the cardiac centres, thus modifying vascular activity; and 2d, that they come in contact with the diseased intestine; here they have an antiseptic effect upon its ulcers, and an antibiotic effect upon any infecting germs developing at those points.

The plan of treatment thus described seems to have had extremely good results. We give it for what it is worth, and would neither advise nor discountenance its further trial. Typhoid fever is not a disease to be trifled with. At the same time it seems to be the fact that in its treatment at present one drug is about as efficient as another in modifying the course of the disease; so that we should be glad to learn if there is something really useful. We hear strong claims for turpentine, for laudanum, quinine, acids, calomel, digitalis, chlorate of potash, and baths of all kinds; there is a list of over forty "efficient and useful" drugs for the disease. All this makes one suspicious; and the fact is—a fact now widely enough understood—that if the patient is properly supplied with food and stimulants, if the temperature is kept below an excessive height, and any special symptoms met as they arise, we have done about all that can be promised just now. If there are drugs which really mitigate the course of the disease, the profession, as a body, does not recognize the fact. We should be surprised to learn that further experience proves Dr. Rothe's plan to be as efficacious as he thinks it is.

THE PUBLIC HOSPITALS AND INSANE ASYLUMS OF THE STATE.

The eighth annual report of the State Charities Aid Association for 1879 has just appeared. The reports of this Association have always been documents of considerable interest. The present one is perhaps less so than most of the others; but as this is because it has fewer evils to discuss, the fact is a matter of congratulation rather than otherwise. During the eight years in which the State Charities Aid Association has been in existence, there have been very marked improvements in the condition of our penal and charitable institutions. Better buildings, better officers, better management, and a better hygienic condition have been secured nearly everywhere. What is more, the people have been brought to take a deeper interest in the condition of those whom they are supporting. In a great many departments things have reached as good a state as is possible under the present system of management, and this system alone is left to be reformed. The curse of most of our public institutions, it has been told us often, is that they are under the control of politicians. The executive officers depend for their position upon their party's supremacy. Their party, therefore, comes first. It is more a matter of chance than anything else if executive officers are good men. We fear that the evils of this state of affairs will have to be accepted with as much grace as possible. It must be a long time before the whole people of this state demand a proper system of civil service, and it will not be until then that such a system will be adopted. Meanwhile, we must accept the advice of Mr. Herbert Spencer, and "unite philanthropic energy with philosophic calm."

Regarding the hospitals and insane asylums of the state, which are the institutions of most interest to us, the report does not have much to say that is new. We are very placidly told, however, that even in the badly constructed hospitals the introduction of trained nurses and the use of antiseptics, "as taught by Prof. Lister," has greatly reduced the death-rate. In a number of the counties there is no proper provision for the treatment of the sick. Paupers, insane, the aged and the diseased, live together in the same buildings. The improvements that have taken place in Bellevue and Charity Hospitals are enumerated and commended. The building of the ventilating towers for Bellevue and of the pavilion for acute surgical cases is certainly of great advantage. It is gratifying to learn also that a physician who pays special attention to nervous diseases has been put in charge of the new pavilion for the insane. In the maternity pavilions on Blackwell's Island there were, in 1879, two hundred and fifty-nine cases of confinement, with eleven deaths of mothers. This is too large a per cent., but it is believed that all possible skill is exercised.

Regarding the care of the county insane in the counties, we hear much the same story as in previous years, although some improvements are going on or have been made. We note eleven counties in which the accommodations for the insane are stated to be either not good or miserably inadequate. The crowded condition of the state asylums allows counties which wish to be thrifty to keep their insane in the poor-houses. A decent silence is preserved regarding the city insane asylums on Ward's and Blackwell's Islands. The state insane asylums do not appear to have been visited. The general tenor of the report shows its appreciation of the difficulties and deficiencies in the care of the state's insane. It could not be expected, however, that a committee of the laity should grasp the full importance of the question; nor do the functions of the State Charities Aid Association call upon it to do so.

◆

LADY HARRIET SCOTT BENTICK has given $20,000 to the International Hospital at Naples, in order to enable the committee to buy or build premises of their own. It is among the conditions of this gift that an English-speaking physician and an English nurse be always kept at the hospital.

POETRY AND MATERNAL IMPRESSIONS.—A Maryland physician, according to the *Dublin Medical Journal*, has reported a case of maternal impression which leaves all ordinary cases far behind. A lady, during pregnancy, carried with her a pocket edition of Moore's poetical works, which she read almost constantly. Her child, at three years of age, exhibited a most wonderful gift of putting sentences into rhyme—in fact, naturally expressed his little ideas and thoughts in flowing measure. Blame not the bard, says the *British Medical Journal*, but a case like this shows how important is a well assorted library to a gravid uterus.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, September 8, 1880.

DR. T. E. SATTERTHWAITE, PRESIDENT, IN THE CHAIR.

CHRONIC BRIGHT'S DISEASE, WITH ACUTE SYMPTOMS AND DEATH.

DR. A. C. POST presented two specimens of urine: one as drawn with the catheter, and the other as prepared by heat and nitric acid. The urine was taken from a patient with the following history: A lady, between forty and fifty years of age, whose health had been somewhat delicate for a number of years, notwithstanding she was a large, stout person, had during the last two or three years passed several quarts daily of light-colored urine, which had been tested and found to be albuminous. As far as could be learned, there had not been positive uræmic symptoms. She spent the summer in the White Mountains, and returned to the city on Monday, the 30th of August, in a fair state of health. On the Thursday next following she had what she regarded as an attack of indigestion, which was attributed to partaking too freely of corn and beans. Dr. Post was called early Friday morning, and found her suffering from intense abdominal pain, which the patient could partially relieve by making firm abdominal pressure She also had vomiting and purging. From the history, Dr. Post regarded it as a case of severe indigestion, and administered a charcoal mixture; but i afforded no relief. He then ordered two teaspoonfuls of the U. S. solution of morphia, to be followed by teaspoonful doses every hour until the pain was relieved. After a few hours, the morphine thus administered having failed to give any relief the dose was doubled, and within less than twenty four hours very nearly two ounces of the U. S. solution were taken before the pain was entirely relieved The nausea continued for some hours after the subsidence of the abdominal pain. Although she had not slept much, having taken such a quantity o morphine and recovered from the pain, she seemed to be drowsy, and her pupils remained contracted On Sunday the drowsiness was more marked, and was attended with a good deal of twitching of the muscles of the limbs. On closer inquiry, it was then found that she had not passed any urine for nearly twenty-four hours. A catheter was introduced, and from ten to twelve ounces of light-colored urine obtained, which was found to be albuminous. Dr Post was then convinced that the drowsiness and muscular twitchings were uræmic in character, and put the patient upon tablespoonful doses of the infusion of digitalis once in *eight* hours, and, as th symptoms became more grave, the interval betwee the doses was reduced to once in *three* hours.

On Monday she had become semi-comatose; th twitchings had increased: a catheter was introduced and only about two ounces of urine were obtained She was then dry-cupped thoroughly in the lumba region, but no more urine was secreted. The com became more complete, and she died on Tuesda morning at one o'clock.

The urine exhibited contained, as reported by Dr Stickler, one-third albumen, had a specific gravit of 1010, an acid reaction, large hyaline and sma granular casts, fat-globules, bladder-epithelium, and amorphous matter.

A post-mortem could not be obtained. One feature of the case, especially interesting, was the sudden suppression without the appearance of blood in the urine.

REMOVAL OF AXILLARY GLANDS—THROUGH DRAINAGE.

Dr. Post also presented a mass of axillary lymphatic glands, with a portion of skin covering them, removed from a lady on the 16th of August, a little less than a year after the removal, by another surgeon, of the mammary gland upon the corresponding side. For several months the patient had had a good deal of pain and some indurated swelling in the axilla, and it was evident that, if she was to be benefited by an operation, no time should be lost. The case was reported especially with reference to the manner of dressing and the healing of the wound. After removing the mass, which was very deeply situated, he resorted to Dr. Markoe's plan of through drainage, consisting in the introduction of a drainage-tube with perforations only within the wound, and injecting through it a solution of carbolic acid, 1 to 40, until the fluid comes out clear. All the stitches and the tube were removed at the end of the second day, and, with the exception of the orifices through which the tube passed, the wound was substantially healed. He thought the mode of dressing superior to Lister's, inasmuch as it is equally effective, and at the same time simpler and more comfortable for the patient.

COMPOUND FRACTURE OF THE SKULL.

Dr. Post also presented numerous small fragments of bone taken from the skull of a boy three years old, who was brought to the Presbyterian Hospital on the 2d of August, having fallen from a third-story window. There was a compound fracture with deep depression in the frontal and extending toward the temporal region, and the dura mater was exposed, though not wounded. He was not entirely unconscious, and could be aroused so that he would answer questions. At that time there was no febrile excitement. Besides the injury mentioned, there was a copious discharge of watery fluid, very slightly tinged with blood, from the ear on the side corresponding with the injury upon the forehead. Dr. Post enlarged the wound, and with a Rongier removed the overhanging edges of the bone, raised and removed all the depressed portions of bone, exposed the dura mater, which was sunken to some distance beneath the surface, and then applied a carbolic lotion. For the first two days there was but little fever, the boy could be aroused, and prospect of recovery seemed to be fair, notwithstanding the grave nature of the injury.

On the third day the temperature suddenly rose to 105° F. or more, coma became complete, and death occurred on the same day. Autopsy, made by Dr. W. H. Porter, revealed extensive fracture through the petrous portion of the temporal bone, as might have been expected, and the fracture also extended through the orbital plate of the frontal bone. There was also rupture of the upper lobe of the right lung.

Dr. Post remarked that the most interesting clinical feature of the case was the discharge of watery fluid from the ear, a symptom which was regarded by surgical pathologists as evidence of fracture through the petrous portion of the temporal bone, and communication with the cerebro-spinal fluid. He believed that cases of recovery after that occurrence were very rare, and that the symptom indicated more certainly a fatal termination than the discharge of blood from the ear.

In connection with the above case, he mentioned another in which the patient, a man, was thrown upon a platform of the elevated railroad, and, together with dislocation of one femur upon the dorsum of the ilium, etc., he was so injured that there was hemorrhage from one ear and a certain amount of coma, with violent excitement that demanded mechanical restraint. He was about thirty-five years old, his pulse was full and strong, his general health had been good previously, and Dr. Post practised venesection, removing twenty ounces of blood. The patient soon became quite calm, and since had done well.

HIP-JOINT DISEASE—EXCISION.

Dr. Post also presented portions of bone which he removed in St. Luke's Hospital, from the upper extremity of the femur of a girl nineteen years of age, who had suffered from hip-joint disease as long as she could remember. There was considerable shortening and deformity of the limb, and several sinuses communicated with diseased bone. The wound was treated upon Dr. Markoe's plan of through drainage, and there had been but little constitutional reaction since the operation. The acetabulum seemed not to be involved. The limb was kept extended by means of weight and pulley for about *two* weeks, and was then put up with a plaster-of-Paris dressing, so that the patient could go about on crutches. The patient's general condition had improved, the original sinus discharged but little, and, notwithstanding the formation of several abscesses since the operation that were opened and still continued to discharge, there was fair prospect that the patient would make a good recovery. The case was especially interesting because of its long duration.

Dr. Putnam-Jacobi asked Dr. Post three questions with reference to his first case: 1st, was not the attack of "cholera morbus" itself an expression of uræmia such as often occurs in advanced stages of renal cirrhosis, when urea begins to be eliminated by the gastro-intestinal mucous membrane; 2d, had not the fatal event been accelerated by the morphine, which, sparing the higher nervous centres, had nevertheless paralyzed the renal nerves, and thus induced a paralytic congestion of the kidney; 3d, might not derivation to the surface by means of the vapor-baths, or of jaborandi, have been of service in the case?

Dr. Post replied that the patient was in a profuse perspiration during her entire sickness, and he saw no special indication for using either jaborandi or a vapor-bath. He was doubtful whether the morphine had anything to do with the suppression of the urine. The necessity for its administration seemed to be absolute because of the severity of the pain, and it was given gradually and carried no further than was necessary to afford relief. He was not aware of the fact that the patient had had albuminous urine for some time when the morphine was administered. *Had* he been, he would have given a large dose of calomel, hoping thereby to have removed the abdominal irritation without incurring the risk of occasioning suppression of urine.

Dr. C. Heitzmann thought that it was evidently a rare case of fatty degeneration of the kidneys; for the small granular casts indicated chronic croupous nephritis which had resulted in fatty degeneration.

The fact that there were large hyaline casts indicated that a new inflammation had developed, involving the pyramidal portion of the kidney; whereas the small granular casts indicated that the narrow tubules were involved; hence a chronic process. Such cases, he thought, were not very common. As far as his observation had extended, having had little or no practical experience in that direction, internal treatment was of almost no value. He was also thoroughly convinced that the presence of hyaline casts in the urine always indicated inflammation and not congestion; that is, mere congestion cannot lead to the formation of casts.

With reference to Dr. Post's case, he was also surprised that blood had not appeared in the urine; for, in fatty degeneration bloody urine is more common than in any other form of kidney disease.

With reference to nitric acid as a test for albumen, it would, he believed, surely dissolve small quantities of albumen, and he therefore advised the use of acetic acid in connection with heat.

DR. PUTNAM-JACOBI remarked that, in itself, the hyaline cast was the immediate result of congestion, although only of the congestion which constitutes an element of acute or chronic inflammation. The fact that in this case the hyaline casts were unaccompanied by hemorrhage, seemed to forbid the supposition that they resulted from a very recent process. They rather belonged to the chronic disease, which there was every reason to suppose existed.

"In a persistent and severe albuminuria, hyaline cylinders (similar to those already described in acute nephritis) are found occupying the uriniferous tubes" (Corneil and Ranvier, p. 1040). Rindfleisch also describes these albuminous (not fibrinous) cylinders as an element of parenchymatous nephritis, probably dependent on extravasations of blood-serum.

THE PRESIDENT directed attention to a practical point in examining urine for albumen. He had frequently been able to detect albumen in urine that had been examined by students and reported as containing no albumen, by observing the precaution of holding the test-tube against a dark background, when the flakes of albumen could be seen rising and falling, that would not be recognized when the tube was held up in the usual manner. In all cases in which there was doubt as to whether or not the specimen contained albumen, it should be filtered until it was perfectly clear, and then acid used, preferably the acetic.

With reference to congestion of the kidney, the President called attention to the following case: A boy, sixteen years of age, came from Michigan to be treated for necrosis of the femur. One year subsequently, Dr. Satterthwaite was called upon to make a post-mortem, the lad having died of scarlet fever after a sickness lasting only forty-eight hours, and during the last twelve hours of his life he passed no urine whatever.

On removing the kidneys, they were found pale and bloodless, except in the pelves and calices, which seemed to be congested and presented an appearance which corresponded exactly with that illustrated by the colored plates of Lebert.

On making a microscopical examination of the organs, however, no congestion was found. The epithelia were fatty.

Some time afterward, while reading "Klebs' Pathological Anatomy," he found that that author mentioned cases in which the only portion of the kidney which was congested was the malpighian bodies. He then returned to the examination of the kidneys in question, and found that their malpighian bodies were markedly congested, and were the only portions of the kidneys that were thus involved. They therefore corresponded to what Klebs has denominated *glomerulo-nephritis.*

DR. PUTNAM-JACOBI said that the interpretation she had offered in Dr. Post's case was quite in accordance with such an interesting fact as that described by Dr. Satterthwaite. In both cases suppression of urine, not preceded by hemorrhage, was the prominent symptom; in both cases the renal nerves had been exposed to the influence of a poison capable of poisoning them—in one the scarlatina poison, in the other the morphine. Ludwig's experiments have shown that lowering the pressure in the branches of the renal artery sufficed to arrest the excretion of water through the malpighian tufts. Paralysis of nerves going to the blood-vessels would reduce the arterial pressure to a minimum, and thus cause fatal suppression of urine without previous hemorrhage, without fever or other sign of *acute* nephritis. This was exactly the clinical combination offered by Dr. Post's case.

CONTRIBUTIONS TO THE PATHOLOGY OF THE SKIN.

DR. C. HEITZMANN exhibited specimens of small-pox, in order to illustrate the microscopical changes in this disease.

In the *papular stage* of the inflammation the epithelia of the rete mucosum are coarsely granular, due to an increase of living matter within the protoplasmic bodies. The points of intersection of the living matter—the so-called granules—become enlarged, the nuclei shining and solid, and the "thorns" which traverse the cement-substance thickened. The underlying papillæ are slightly enlarged, partly due to the engorgement of the blood-vessels, partly to a transformation of the bundles of connective tissue into protoplasm. After liquefaction of the glue-yielding basis-substance, the reticulum of living matter, formerly hidden therein, becomes visible.

In the *vesicular stage* the exudation makes its appearance, and by the breaking apart of the reticulum of some epithelia a small cavity becomes visible, or several such cavities had formed, and thus the separating layers of the epithelia are compressed and produce septa between the cavities. The epithelia bounding the cavity look very coarsely granular, and having partly lost their enclosing cement-substance, are transformed into protoplasmic clusters, with many shining nuclei. In the exudation filling the vesicle there are suspended granules of coagulated albumen and a varying amount of coagulated fibrin. The papillæ have disappeared, the uppermost layers of the derma are replaced by indifferent, or medullary, or inflammatory elements, all in connection with each other through delicate threads of living matter.

In the *pustular stage* of small-pox, pus-corpuscles appear in the cavity within the rete mucosum, which mainly arise from the epithelia traversing and bounding the cavity. How many of the pus-corpuscles have appeared through an immigration from below we do not know. According to the amount of living matter present in the pus-corpuscles, the pus is thick and yellow, or serous and pale. The connective tissue, as a rule, does not advance beyond its reduction into a medullary tissue; in some cases, also, the medullary elements are torn asunder, and now represent pus-corpuscles, which commingle with the pus sprung from the epithelia, and share in the formation of the abscess.

Dr. C. Heitzmann also exhibited specimens of *angioma of the skin* (vascular or erectile tumor, formerly so-called teleangiektasia). He distinguishes three varieties: 1. *Angioma simplex*, a new formation of capillary blood-vessels, mainly in the upper layers of the derma, leading to the appearance of a uniform, flat, dark red spot, so-called nævus flammeus. 2. *Angioma lobulare*, in which the newly formed blood-vessels are coiled up in lobules, which latter are separated from each other by a fibrous connective tissue. 3. *Angioma cavernosum*, with large spaces, imitating the structure of the cavernous body of the body, filled with venous blood, and holding a variable amount of connective tissue. The most common vascular tumor of the skin is the *myxo-angioma*, with numerous large capillary blood-vessels held together by a myxomatous connective tissue. All dark red, mostly sessile, not fully compressible tumors of the skin, often only slightly protruding above the level of the skin, belong to this variety of mixed tumors.

Dr. C. Heitzmann lastly demonstrated specimens of *adenoma of the skin*, which almost exclusively is a new formation of the sebaceous glands. Such tumors are very prone to be transformed into *cysts*, with varying contents. A watery fluid is present in *serous cysts;* a viscid, honey-like fluid in the *meliceris:* a smeary, offensive, pasty liquid in the *sebaceous cyst;* an almost dry, slightly rancid, pearl-colored mass in the *dermoid cyst*. Careful examination of cysts, both of the skin and the ovary, results in the assertion that cysts never are primary formations, but always due to secondary changes of adenoma. The liquefaction or accumulation of epithelia is the exclusive source of formation of cysts, which therefore must run in the system of tumors as formations secondary to adenoma.

Dr. Post asked, are not cysts sometimes produced by obstruction of ducts of glands; for example, as in ranula?

Dr. Heitzmann replied that researches in Germany concerning ranula rejected the conclusion that simple obstruction ever produced a cyst. It was to be confessed, however, that pathologists were somewhat in the dark with reference to the etiology of ranula.

Dr. Post remarked that he had seen a ranula over which Wharton's duct could be traced distinctly. It was, however, an exceptional case.

The President referred to one form of angioma not mentioned by Dr. Heitzmann, namely, that existing in the connective-tissue planes, and called by one German writer *hyperplasticum*. He had seen one specimen removed from the orbit.

Dr. Heitzmann remarked that he had not seen that variety in the skin.

TUMOR OF THE BRAIN.

Dr. F. M. Hamlin, of Auburn, N. Y., on invitation, then presented a tumor of the brain, accompanied by the following history:

He was called in consultation, on May 10, 1880, with a number of the physicians of Auburn, to see Dr. D. H. A——. The history of the case as then given by the family was as follows: Age, 53; physician; habits strictly temperate and correct. For five or six weeks previously he had suffered from a severe headache, with the pain confined almost entirely to the occipital region, and it increased in severity until May 1st, when he put a blister on the back of his neck and was greatly, if not entirely relieved. On May 3d he received a telegram from New York to come and attend one of his old patients, and he went at once in response to the call. While in the city the pain returned in the occipital region and he acted somewhat strangely, but attended to his patient, and also sent for another patient to come from Auburn to the Women's Hospital and have an operation performed. Although he suffered intensely and appeared somewhat abstracted at times, he seemed to have performed his duties correctly. His patient at the hotel died, and he returned to Auburn with the remains on May 9th. As soon as he was met at the depot by his friends, they saw he acted strangely and seemed very ill, and they insisted upon his going to his home at once. He did so, and, finding a patient waiting in his office, prescribed for her and then went up to his family. After giving them a somewhat disconnected and jumbled account of his visit to New York, and how he had suffered from the pain in his head while there, and was then suffering from it, he went to bed and soon began to sleep.

Dr. J. D. Button was then sent for, who prescribed a mercurial cathartic, bromide of potassium, and rest. He slept nearly all day, and after the action of the cathartic seemed relieved. The next morning he had a serious "sinking spell," or period of depression. Stimulants were used, and he revived; but as his sleep had now become almost semi-comatose, a consultation was called. His condition at this time was as follows: when roused up, he would recognize his friends, shake hands, speak, and answer questions correctly, but would fall asleep the moment he was let alone, and sometimes before he would finish a sentence. The pain in the head was entirely gone. There was some thickness and indistinctness of speech, tongue coated, protruded promptly and straight out. When asleep, his lips drew in and puffed out with each respiration. Pupils not contracted, equal, and responded to the light. Pulse 65, and not very strong or full. Temperature was a little below 98° F. in the axilla. Moved his limbs readily enough when told, and there were no symptoms of paralysis, unless the thickness of speech and a slight drawing up of the left corner of the mouth were to be regarded as such. Concerning the latter, the doctor said he had received a cut on that side of the face, and that the drawing up of the corner of the mouth was the result, and Dr. Hamlin could recall the fact that he had noticed, as had others, this drawing up of the left corner when Dr. A. smiled, but at times it did certainly seem exaggerated. One member of the family said she had noticed it before the patient went to New York, and said she did not like to see him smile because it was so pronounced. So far as any mental change was concerned, nothing had been noticed, except that he was abstracted at times, and had given some of his friends the impression that he was offended and displeased with them. No importance had been attached to these symptoms, for they were supposed to be the results of overwork, and, indeed, to this cause was largely attributed his present condition; that exhaustion and an enfeebled circulation had produced a passive venous congestion, and that a low grade of meningeal inflammation had been the cause of the pain he had suffered at the base of the brain.

The plan of treatment decided upon was to renew the mercurial cathartic, continue the bromide of potassium, and to use ergot if there was not a speedy improvement. After the cathartic had acted, the patient seemed better, for he continued free of pain, and would answer questions more promptly, and the sleep was less profound.

Having been requested to assist in the care of the case, Dr. Hamlin remained during the night, and soon after midnight found that Dr. A.'s temperature began to fall; and fearing another "sinking spell," he at once began the use of stimulants and external heat, and in a measure prevented it, but the temperature went down to 97° F. in the axilla. May 11th was but a repetition of the day before, only the patient steadily grew worse. May 12th, in the morning, there was another lowering of the temperature and an increase of the stupor. He then hardly recognized his friends, and required a good deal of shaking and loud, sharp talking to rouse him at all. May 13th.—Just after midnight his condition seemed almost hopeless. He was breathing fifty and fifty-five times per minute, and seemingly with the air entering only the very uppermost part of the lungs. His face was of a dull, almost purple color. Temperature, 98° F. Pulse about 100, and very feeble. Dr. H. began the vigorous use of mustard to the spine, over the epigastrium, calves of the legs, etc. Dr. A. showed no signs of pain from the mustard, although it was kept on almost to blistering, but he would flinch from a slight prick of a pin. After an hour or so, Dr. Hamlin was gratified to notice a change in the respirations; they became slower and deeper, and as a consequence the color of the face began to change to a more natural hue. By daybreak it was apparent that reaction had fully set in. The pulse was 90, temperature, 100° F., the first time it had been above normal. A few leeches were then applied behind the ears, but they produced no appreciable effect.

As the day passed on it was evident the patient was improving, the sleep was less profound, and he could be readily roused to take food and medicine. About 4 P.M., after an unusually hard time rousing him, in which he was shaken roughly and slapped in the face with a wet towel, he suddenly waked and apparently in the full possession of his mental and physical powers. He greeted those about him with pleasure, talked of his visit to New York, his voice was strong and clear, memory unimpaired, and, excepting his physical weakness, he seemed as well as ever. The first ebullition of joy over, quiet was enforced, and except a tendency to falling into deep sleep and weakness, nothing seemed to remain to remind him of his illness.

Everything went on favorably for four days, when his bowels became irregular and constipated, and then his mind began to wander. He was back on the old camp-grounds of the army, trying to escape from the noisome effluvia of old sink-holes and the stench of too shallow graves. A twenty-grain dose of calomel was given, and with a most happy effect, for when his bowels were relieved his mind cleared entirely. He then gained rapidly. With slight support on either side he walked about the house. But in the course of a few days his bowels became deranged, and again his mind was clouded. Another twenty-grain dose of calomel was given, with equally happy effect as before, only it could be seen that he was just a little less active than before, both mentally and physically. He had for many years been affected with catarrh, and just then the secretion became much increased and very tenacious, and it seemed to collect in his throat, and caused him to strangle quite badly once or twice when taking food. Twice more were large doses of calomel given for conditions like those described, and each time with benefit; but each time the mind was left more sluggish and inactive. His remarks sometimes showed that his mind wandered; his replies to questions were correct, but came slowly, as if they cost him an effort to collect his thoughts. He was quite disinclined to talk. His appetite was good most of the time, and he frequently spoke of the relish with which he enjoyed it. From the fact that the evacuations, after taking cathartic medicines, the calomel especially, were very large, apparently quite out of proportion to the amount of food taken, and that there were some hardened fæcal masses, Dr. Hamlin suspected that there was an accumulation of fæcal matter in the bowels. The doctor frequently spoke of the great relief the first dose of calomel gave him, and said he felt as if it had started some "hard lumps;" but as Dr. A. had said his bowels were tolerably regular before his illness, Dr. H. did not then give much attention to it. The thick mass of fat in the abdominal walls did not permit a close examination, so a mixture of ox-gall, aloes, and calomel was given him, commencing June 1st, and the result was several large evacuations of horribly offensive fæcal matter, with some hard masses in the first few dejections.

On June 6th, Dr. H. found his patient quite stupid and a little feverish; temperature about 101° F.; pulse 100. Upon inquiry he found that the urine had been scanty all day, and on getting some the next morning he found it to contain a small quantity of albumen and long mucous casts. The urine was examined in the beginning of his illness, but neither casts nor albumen were found. The next day the quantity of albumen was greatly increased, and the temperature was 103° F. He now failed rapidly. June 8th, in the evening, in attempting to take some beef-tea he strangled badly and came near suffocating. He was relieved by drawing out the tongue, and clearing the throat by means of the fingers, but he never recovered from the shock, and died the next morning, June 9th, without a convulsion or spasmodic action of any kind, except that subsultus tendinum had been present to a slight degree for the last three days.

At the autopsy, performed fifty hours after death, the head and abdomen only were examined. The body was well nourished, no loss of flesh having occurred apparently. The abdominal organs appeared to be in normal condition, except that the kidneys seemed slightly enlarged and congested, and there were some hard fæcal masses in the colon.

On removing the brain it was noticed that the vessels on the superior surface were somewhat congested, but nothing very remarkable. At the base and over the posterior of it were evidences of meningeal inflammation. The membranes were thickened and opaque in places and the vessels enlarged, and between the cord and cerebellum were slight bands of adhesions. In the right ventricle were three or four drachms of serum, and two small cysts filled with a clear liquid were found in the choroid plexus. No other abnormal feature was discovered till a section was made through the *left frontal lobe*, when a tumor of about the diameter of a small hen's egg was discovered. It was harder than the surrounding brain-tissue, reddish in color, and apparently quite vascular. Its boundaries were not well marked, and the color faded away into that of the normal tissue surrounding it. It seemed to be confined wholly to the white portion of the brain, and occupied all that part of the white matter of the frontal lobe which a body an inch or an inch and a quarter could do, with its anterior border just touching against the gray matter of the front of the lobe, and covered by the second and lower part of the third convolution when looked at from the side.

After the autopsy revealed the location of the tumor, the history of the case was looked over carefully to see if there were any of the characteristic evidences present during life to locate the trouble in that region. First, pain in the frontal region was a rare thing. Secondly, speech was but little affected and only temporarily, and there was no convulsion, epileptiform attack, or hemiplegia, and so far as known the special senses were intact. The pupils were equal, and responded to light all through his illness. In regard to any paralysis, the temporary difficulty in swallowing, and the drawing of the left corner of the mouth were the most marked. The mental symptoms might be such as are said to accompany lesions in this region. During the progress of the case it came to be known that the pain at the base of the brain had troubled the doctor at times for over four years, and very severely occasionally.

Dr. Putnam-Jacobi remarked that the case was a very typical one of tumor in the frontal region, because of the absence of paralysis and the presence of change in character manifested by the patient. It seemed evident that there must have been some affection of several of the centres of motility at a distance, because of the change in respiration and the partial paralysis of the hypoglossal and the pharyngeal branch of the pneumogastric.

The President suggested that those symptoms might have been produced by the pressure caused by the fluid in the ventricle of the brain.

The Society then went into Executive Session.

Correspondence.

PORTAGIOUS: THE PROPER WORD TO DESCRIBE THE ETIOLOGY OF CERTAIN ZYMOTIC DISEASES.

To the Editor of The Medical Record.

Sir:—The admitted conditions under which certain of the zymotic diseases are now known to appear give their etiology a peculiarity which we have no word to describe. The want is not met by such words as contagious, infectious, epidemic, endemic, etc., as these are exceedingly elastic when used to assign a cause for such diseases as yellow fever, enteric fever, diphtheria, etc. They are even convertible terms, which have to the professional mind a vague definition, and the difference between contagion and infection, when sought by the popular mind, finds simply an impassable barrier.

There can be no question regarding the necessity in medicine for a word to describe the conditions under which zymotic diseases are propagated, and this may soon extend to other diseases if some experiments recently made by Cohnheim shall prove true, in which the communication of tuberculous matter was made from one individual to another, and the disease reproduced. The words contagious or infectious do not give the necessary etiology when we speak of yellow fever, typhoid fever, or diphtheria. They all may become epidemic. Their etiology cannot be conveyed to another mind by using the above adjectives, and I therefore propose, for these and similar diseases, to imply the conditions of causation under which they appear, the word Portagious.

This word describes the portable character of the yellow fever germ, or atmosphere, which may be briefly illustrated by two of the most striking selected from endless instances, viz.: 1, the case of its transportation from Havana, Cuba, to St. Nazaire, France, in the ship Anne Marie, after a long passage of fifty-three days, including the breaking out of the ship at St. Nazaire; 2, the case of the ship Hecla, which carried the disease from Cuba in the same year (1865) to Swansea, Wales, where it spread rapidly, in which the germ survived a passage of forty-five days. The foregoing from the report of Hon. John Simon, Chief Medical Officer of Great Britain.

The word also describes the portability and contagious character of typhoid fever, as we have numerous instances wherein this disease has been carried in milk, and in water which contained the disease germs. The distant propagation of this disease is illustrated briefly in the case of its transfer in the American ship "Flying Cloud," in 1864, when it was carried from Liverpool, England, to Melbourne, Australia, through a passage of sixty days. Before this the disease was unknown in Queensland. For further facts in this connection see *The Lancet*, review of Mr. William Thompson's "Report on Typhoid Fever," Melbourne.

The above trifling references are only intended to show that the facts of portability and contact are the real conditions under which these diseases reappear, and this particular part of their history the word portagious is intended to describe. Portability is a leading idea in the causation of every disease, whether the power be derived from animal life, steam power, the force of wind or wave, or the current of flowing water, and hence I am persuaded that the word will be found useful in sanitary and state medicine. When reference shall be made to yellow or typhoid fevers, as portagious, it will be understood that they are capable of transportation over great terrestrial distances, while they can be as readily absorbed if the individual be moved into the focal points of disease themselves.

The word is compounded from the Latin *porto*, to carry, French *porter*, and Spanish *portear*, and *tango* or *tago*, to touch.

The concise definition is, *to carry into contact*, and is precisely the prerequisite for reproducing a disease, the germs of which are portable.

Respectfully,
B. F. Gibbs,
Medical Inspector, U. S. Navy.

TREATMENT OF HEMORRHOIDS BY INJECTION.

To the Editor of The Medical Record.

Sir.—My letter to the Record of September 11th, on this subject, has shown several interesting points, among which may be noted the extensive circulation of the Record, the desire for more minute information as to the operation, and the anxiety of the profession at large to avail themselves of this method of treatment, despite the alleged superiority of other plans, all of which they will discard, as I have done, after they try this better way. The numerous letters which I have received from all parts of the union conclusively prove this. The first half-dozen were answered individually, but time will not admit of replies to the questions asked (some of them pertinent and others irrelevant), except through the able journal which has brought this flow of correspondence upon me. In brief, therefore, the following points are stated, with the hope that the ground may be covered to the satisfaction of all concerned.

1st. *The acid.*—I always use crystallized *carbolic* *acid*, enough glycerine (a few drops only) being added solely to render it *fluid*, not in any way to *dilute* it. My reason for departing from the method of others is that dilute solutions are absorbed, the rapidity thereof being in direct proportion to the thinness of the acid employed. This is evidenced by the patient *tasting* the acid after its injection, by disturbance of the general circulation, such as depression, faintness, and pallor. Concentrated acid acts locally, instantly, and thoroughly, and proportionately to the strength employed is the assurance of non-absorption.

2d. *The operation.*—Empty the bowel thoroughly by Hathorn Saratoga water, or its equivalent, the day before, and the rectum by enema an hour before operating. Do not inject during acute inflammation—"a fit of the piles." Put the patient in bed. Anoint the mass of tumors, after their extrusion, with *fresh* olive oil or cosmoline, to prevent accidental caustic action on the adjoining parts, especially in females. Use a good glass hypodermic syringe, with a tight piston, which moves easily, and a small, well-polished, and sharp needle. See that the needle is pervious to the acid (not to water) before commencing. Select the largest pile, and push the point of the needle to the *centre* only, and not beyond the tumor, then slowly inject from three to six drops. If the pile is as large as a small walnut, I put in three drops at one point, partially withdraw the needle, and deposit three drops at another point, and sometimes at a third. Inject only one pile at a time, unless they are small, when two may be attacked at one operation. Keep the needle *in* the pile for a few seconds before withdrawing it fully. The object is to permit the mass to harden before taking the needle out. If the pile bleeds, touch it with a piece of ice or the strong carbolic acid. Nothing worthy of the term "hemorrhage" has ever occurred to me, and I don't believe it can. No bleeding resulting, thoroughly anoint the tumors as at first, and return them within the sphincter. A suppository may also be introduced, but I prefer morphia hypodermically. I do not combine *anything* with the acid, although it has been suggested to add the morphia to it. Better use them separately. Keep the patient in bed, and in two or three days inject another if it exist, and repeat at this interval until all are done. The process mummifies and shrivels the hemorrhoids, and does not cure by inflammation. Now and then the whole or a part of the pile may slough, but the process is limited. If the acid goes into the cellular tissue, of course we will have trouble, just as in any other part of the body, but it has no business there. I only inject *internal* hemorrhoids, but for curiosity I, within ten days, injected a complete fistula, and the result has been a cure.

3d. *The result.*—After injection more or less pain is experienced, which is readily controlled by anodynes. Usually nothing beyond discomfort is felt, frequently not even that. The catheter may be needed, especially in old men, as in any other surgical interference in this locality. Any febrile reaction is treated by one-drop doses of tincture of aconite, repeated at intervals, and in debilitated subjects from two to five grains of sulphate of cinchonidia is *given* (not *exhibited*) three or four times daily. Light, unirritating, digestible diet, such as produce little fecal residue, no stimulants, and perfect rest is enjoined, until the end of a week, when the bowels may be gently moved, preferably by salines. After an uncertain, at least an undetermined time, the tumors disappear almost entirely, two post-mortems of persons dying from other disease about thirty months after operation showing only thickening of the mucous lining above the sphincter.

4th. *In conclusion.*—The operation is simplicity itself, it is almost painless, and rarely requires an anæsthetic; it is successful, and applicable to all varieties of hemorrhoids. I have given my own plan, with reasons for deviation from other modes, but, as is well known, all great surgeons modify everything in the way of instruments and methods of operating; the profession at large is therefore at liberty to do this operation in their own way—as it would not, by any manner of means, be compatible with dignity or self-respect to make it so unimposing as this narrative sets it forth.

William R. D. Blackwood, M.D.

NITRITE OF AMYL IN CONVULSIONS.

To the Editor of The Medical Record.

Sir:—Willie R., aged two years and six months, while at play on the morning of August 12th, was suddenly seized with convulsions. I was immediately summoned, and on my arrival I found the child in an unconscious state, one convulsion following another in most rapid succession. The convulsive movements were confined almost entirely to the right side. My first impression was that the convulsions were due to functional derangement of the stomach and bowels, and the usual remedies indicated in such cases were resorted to, but no benefit followed the same. As the child was, in the meantime, rapidly becoming exhausted, and the necessity of doing something to control the convulsions more evident, I resorted to the use of chloroform and ether, but without succeeding in controlling the convulsions. I then used nitrite of amyl by inhalation. Placing four drops on a handkerchief, I applied it to the child's nostrils, and after a few moments had passed, the convulsions ceased entirely, and did not occur again till yesterday morning, August 13th, but were immediately controlled by four drops of amyl nitrite, and have not occurred since. A closer examination of patient reveals that the convulsions were evidently due to some cerebral lesion. The cranium is markedly asymmetrical; pupils unequally dilated, the left being much larger than the right. The head is not abnormally large, but the posterior fontanelle is perceptible, union not having taken place between the bone, and remarkably large, being an inch and a quarter in diameter at its base. There is evidently some serous effusion in the membranes of the brain. Child is now taking:

℞. Potass. iodidi	gr. x.
Brom. potass.................	gr. xl.
Aquæ	āā ℥j.
Syr. rhei.....	

Sig.—Teaspoonful t. i. d.

Child is well nourished, appears strong and healthy. On questioning the mother, I ascertained that she has lost two children, both dying in convulsions, which were like this one. I have used the amyl nitrite in a large number of cases, and, with few exceptions, it has been followed with good results. I usually administer five minims, dropping it into a small sponge, allowing the patient to inhale it. It causes the face to flush, and stimulates the lachrymal glands to a considerable extent. Great care should be used in the administration of the drug, as serious consequences might result from its injudicious use.

LEONARD F. PITKIN, M.D.,
Formerly Assistant Physician, Female Insane Asylum, Blackwell's Island.

RAVENSWOOD, LONG ISLAND.

LIQ. OPII COMP. AND TINCT. OPII COMP.

(Squibb.)

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—The difference between these two preparations does not seem to be generally appreciated by druggists, and twice during the present year has the tincture been dispensed to me instead of the solution. In one case the patient referred to some peculiarity in the taste of the medicine which led me to examine it, and I found that instead of the anodyne my patient had been using the diarrhœal mixture. In the other case I called personally for the liquor opii compositus, and the druggist gave me the tincture from a bottle on which was Dr. Squibb's printed label, giving a minute description of the liq. opii comp. On dropping some of this into water, at the house of the patient to whom I wished to administer the medicine, I noticed that there was again the substitution of the tincture for the solution. The druggist had labelled the small vial which he gavè me Squibb's compound tinct. of opium, although, as stated above, the bottle from which he had dispensed it was marked with Dr. Squibb's printed label of the *solution*. When I showed him the discrepancy he insisted obstinately that the two preparations were the same.

These mistakes occurred in very respectable drugstores, and I think it is not very surprising, since the names of the two preparations are so nearly alike. If no change in the names should be considered advisable, it is well to know that the tincture, when mixed with water, makes an opalescent fluid, and has an odor of chloroform, while the other produces scarcely any discoloration in usual doses. I have been in the habit of using the liquor opii compositus for several years, and found it an excellent preparation. Small doses, of ten drops, for example, seem to produce pleasant anodyne effects during the course of diseases like pneumonia, without any disagreeable reaction.

It is very desirable that it should be so clearly distinguished from the tinctura opii comp. that neither this nor the tinctura opii camph. should be dispensed in place of it.

F. A. BURRALL, M.D.

THERAPEUTICAL NOTES.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—I transmit to you some formulæ which I have found exceedingly useful, after careful, repeated trials, for the following affections, from which patients who consulted me, either in my private practice or in my gynecological class in the Mount Sinai Hospital, Out-door Department, in this city, were suffering:

PRURITUS VULVÆ.

This exceedingly obstinate disease I have often permanently relieved if caused by an erythema, intertrigo, acne, eczema, or prurigo produced by vaginitis or endometritis. In the former, by warm injections of flaxseed tea with a solution of the aqueous extract of opium, together with a sitz-bath, lukewarm, twice daily for twenty or thirty minutes, and the subsequent irrigation of the vagina by means of a fountain syringe and adding from one-half to a teaspoonful of the sulphocarbolate of zinc to the quart of water, used every two hours while the patient lies in the horizontal position with her hips well raised. After each vaginal irrigation a tampon of carbolized or salicylated cotton, with some unguent plumbi and belladonnæ, is introduced into the vagina so that it prevents the external parts from being bathed in the secretions, often mucous, sometimes muco-purulent—which cause the excoriations at and around the vulva, the nates, and the inside of the thighs—and directing the patient to use in the evening, and also for one hour in the afternoon, applications of black wash—aquæ phagedenicæ nigræ. Where the pruritus or prurigo disturbs the patient's sleep, a hypodermic injection of morphia is given. The pruritus itself is greatly relieved, besides the above medication, by application of dilute tincture of iron or a twenty per cent. solution of carbolic acid. The most useful of all applications, however, for pruritus vulvæ, I have found the application of the balsam of Peru, of which I use the following:

℞.	Pulv. gummi arabic............	ʒ ij.
	Peruvian balsam....	ʒ j.
	Oil of almonds.................	ʒ jss.
	Rosewater.....................	ʒ j.

M. S.—Apply freely with a camel's-hair brush, eight or ten times a day, to the itching part.

This latter prescription, which has been first suggested by Hufeland, I have also used for the past nineteen years, with the most happy results, for sore nipples, applied every hour for a few days. It has never failed in my hands to cure this troublesome affection. I prefer this prescription to the use of borax and alcohol, the nitrate of silver, the zinc ointment, or the saturated solution of borax, highly recommended by others.

If the pruritus vulvæ is dependent upon diabetic urine, I have found, in addition to the means herewith recommended, the daily internal use of from six to eight drachms of glycerine, in teaspoonful doses, extremely beneficial. If dependent upon granular vaginitis, I am in the habit of touching each granule, after first scraping it off with the curette, with an exceedingly fine point of nitrate of silver.

The endometritis, if this is the cause of the pruritus vulvæ, is treated with laminaria or the curette; if dependent upon polypoid or fungoid or adenomatous multiple growths within the cervical canal or the cavity of the uterus, after which, if the whole uterine cavity has been dilated thoroughly so as to admit the finger to the fundus uteri, which generally takes, by means of laminaria, about thirty-six hours, with Churchill's tincture of iodine applied every three to four days; or, if there is much sensitiveness, I apply carbolic acid, drachma semis to the ounce of glycerine, upon the flexible uterine applicator, down to the fundus, leaving it in contact from five to ten minutes; or I irrigate the uterine cavity through a No. 6 male flexible catheter with a three per cent. warm solution of carbolic acid, always taking care, of course, not to make any intra uterine application unless the canal be thoroughly dilated, and that there is no inflammation in the substance of the uterus or its adnexa.

I have, within the last nineteen years, thoroughly tested the medication herewith recommended, and I have yet to see a case where I failed to permanently cure the most obstinate cases of either pruritus vulvæ, vaginitis, or endometritis, and the sore nipples which often undermine the health of mostly nursing women with very delicate skins.

In communicating these notes I claim no originality in the application of the medication recommended. The treatment has proved highly satisfactory in my gynecological practice, and I desire to recommend it to thousands of the readers of the MEDICAL RECORD who have not tried them.

Respectfully yours,
RUDOLF TAUSZKY, M.D.

211 EAST SEVENTY-SEVENTH STREET, NEW YORK.

HYSTERO-EPILEPSY, OR HYSTERIA MAJOR.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—In a letter which I forwarded to the RECORD some few days since, I enumerated, as observable, at Salpêtrière, in the service of Prof. Charcot, a certain number of interesting subjects of study. But the extended scope of these subjects, the time at my disposal, as well, also, I fear, as the patience of your readers, will scarcely allow of that full discussion which under other circumstances would be desirable. I must, therefore, content myself with my first plan of more or less fragmentary notes.

There are many reasons why we should begin our observations with hystero-epilepsy. It is not alone that this disease is studied carefully and with a large number of patients at Salpêtrière, and that in itself it offers many attractions, but there is, furthermore, the consideration that around it, as a central point, are grouped, in various degrees of relationship, a variety either of associated or of dependent phenomena which we would like to glance at. Hypnotism, catalepsy, somnambulism, and the æsthesiogenic influence of metals (burgism), and of magnets, all seem to be the peculiar properties of hystero-epileptic patients.

It would not, of course, be allowable to reverse this statement and say, that every person susceptible to being hypnotized or mesmerized, to the somnambulic or cataleptic condition, or impressionable to metals and magnets, is a hystero-epileptic, for the latter term conveys the idea of a severe form of convulsive attack; but, certain it is, in the main, that these peculiar exhibitions are demonstrable in greater or less perfection in this disease.

Professor Charcot has proposed to enlarge the signification of hystero epilepsy by substituting for it the term *hysteria major*. Indeed, as matters tend now, there seem to be grounds for entertaining the opinion that all the varied phenomena above mentioned, whether occurring in male or female, may finally range themselves under this simpler title; though I have no authority for stating that the distinguished teacher alluded to would yet use this term in the broader sense I have just indicated. Be this as it may, we return without further discussion to the simple fact that around hystero-epilepsy, or more properly speaking, then, hysteria major, all these phenomena alluded to are in many instances grouped, and this, too, not alone during the few days in which the hystero-epileptic state itself ("l'état de mal hystéro-épileptique") exists, but also at any time during the long continuance of the disease. A single very important exception is the fact, now seemingly well established, that the magnet and other æsthesiogenic agents (metals, static electricity, the diapason, etc.) will produce either a transfer of an existing hemianæsthesia to the opposite side, or will, indeed, provoke a return of sensibility to an anæsthetic member, in conditions of anæsthesia arising from organic lesions (cerebral hemianæsthesia of Charcot). Clearly, this is a novel contribution to the treatment of hemiplegia, and it may yet have a share in changing the gravity of our prognosis in such cases. For the present, however, we leave the exception out of sight and proceed at once to examine the "great neurosis," hysteria major.

It is understood at once, of course, that this is a more or less permanent disease—that it presents various permanent symptoms, chief among which are the general or localized hemianæsthesia, the ovarian hyperæsthesia, and the periodically occurring convulsive seizures. It is the latter known as the hystero-epileptic attack which forms its most striking feature. And this attack furnishes us with an excellent starting-point of which I gladly avail myself at once, since, this very morning, I had an opportunity of watching it in all its details, and with the careful explanations of Professor Charcot, in the instance of a young woman named Dorizon.

After the usual morning cases had been disposed of, we entered the ward to visit this patient. She was then undergoing a series of attacks, which, however, for the time, were being held in abeyance by the aid of mechanical ovarian pressure. Dorizon lay calmly in bed, appearing quite her natural self, but with an apparatus encircling her waist, which is most quickly described by comparing it to an abdominal tourniquet—a strong elliptic band of steel passing around the body, penetrated in its upper portion by a powerful screw on whose lower end is attached a pad the size of a hen's egg. This pad can be forced by the screw down upon the ovary of one side or the other, and kept there at any desired degree of pressure.

Having called attention to this piece of mechanism, and to the natural condition of the patient, Professor Charcot requested the attendants to remove the apparatus. The patient expressed herself as strongly opposed to this plan and made some resistance, knowing well what would happen. Her scruples, however, were overcome, the screw loosened, and the apparatus removed. The effect, or rather one should say the result, was almost instantaneous. The removal of the pressure upon the ovary was simply like taking the brakes off of a machine wound up to go a certain time. The attack or "fit" at once began.

That the reader may be able to follow more intelligently what occurs, I place before him the four periods into which Prof. Charcot has divided the hystero-epileptic attack. These are:

1. Epileptoid, consisting of three phases, viz., *a*, tonic; *b*, clonic; *c*, resolution.
2. Contortions and violent movements.
3. Passional attitudes with hallucinations.
4. Terminal and delirium.

Single attacks as above delineated may last anywhere from five to fifteen minutes, and from twenty to two hundred of them may occur in a day, thus forming a *series* characteristic of the "hystero epileptic condition." This hystero-epileptic condition lasts from one to several days, and the patient then returns to a comparatively normal state. It may be easily diagnosticated from the analogous epileptic condition, likewise presenting a series of seizures, by keeping in mind the following points: there is no elevation of temperature; the seizures are arrested by pressure upon the ovaries; there are probably certain hysterogenetic regions where excitation will bring on attacks.

But as we have said, pressure was no sooner removed than the attack began. First, a pallor of the face, momentary, however, and straightway changing to a congested red; then a slight gasp, showing a constriction in the larynx; then a slow movement of the globes of the eyes upward, until the pupils disappear beneath the upper lid, and already the patient has completely lost consciousness.

At the same moment the head stiffens backward, throwing out into marked contrast the now swollen neck, the respiration has ceased or occurs in gasps, the facial muscles are contorted into a variety of fixed grimaces, the shoulders are raised and drawn forward, while the arms proceed to perform a peculiar rotatory movement, first rigidly and slowly flexing, then pronating, and again extending to their extremest limits, with the dorsum of the hand and the whole arm stiff, like a bar of wood, and held rigidly alongside of the body.

And simultaneously with the occurrence of these phenomena in the upper part of the body, tetanic movements are taking place in the legs. These latter are rigidly extended, though the ankles, like the wrists, are flexed. The patient's whole body is now in a state of perfect tetanic rigidity. This phase, long as it takes to describe, and long as it appears to the spectator by reason of its painful nature, ceases in about half a minute. It is evident at once that we have witnessed the tonic phase of the first period. But now, all at once, begin a succession of quick and jerking movements of the entire body, shaking the patient back and forth violently, and increasing in force up to a certain acme. It is evident, also, that this is the clonic phase. It also lasts some half a minute or more; then succeeds a perfect resolution; the muscles are relaxed, and the body lies flaccid; the face congested; the eyes closed; the respiration stertorous, and a slight amount of foam makes its appearance at the mouth. This phase of resolution occupies two or three minutes.

The whole scene, thus far described, presents, as the reader at once recognizes, a typical picture of an ordinary epileptic "fit." Here is loss of consciousness, and the regular stages of tonic and clonic spasms and resolution, with foam at the mouth and visceral spasm. This period, then, is well named epileptoid. Its duration is usually, as in the case of Dorizon, about three to five minutes, the tonic and clonic phases consuming much less of this time than the phase of resolution with stertor.

But the attack is by no means ended. A few seconds of silence follow the stertor, and now Dorizon enters the second period. Lying flat on her back at the outset, all at once she begins a series of violent bounding movements of the body, executed by suddenly arching the back upward until she rested on the vertex and the balls of the feet, and then dropping back on the bed and flexing her body in the opposite direction, to gain a start for a new opisthotonos. The scene, what with these bounding movements, becomes a very violent one, until she suddenly remains fixed, bent like a bow, resting now only on her head and toes, in the position called l'arcade cercle. Soon the body again falls to the bed, and Dorizon goes through with various contortions, uttering at the same time cries, and struggling to escape, as it afterward appeared, snakes, which she believed were trying to bite her. Her appearance is maniacal.

Another short silence now ensues as the patient enters the third period. Her manner has changed; her face expresses delight; she is evidently under the influence of vivid hallucinations—in most instances, as in hers, of a sexual character. This stage, with Dorizon, was short, but was very characteristic with Witt, another patient of the same kind, seen half an hour later in an attack. Witt's every motion and look expressed that she was at the same stage of the sexual orgasm.

The fourth or terminal period was equally well defined. Dorizon returned to her senses and looked about her intelligently, though evidently under the influence of hallucinations. She still imagined that snakes were trying to bite her, and in the next breath would talk of a man at the window whom she regarded as a lover.

Such is a regular hystero-epileptic attack, as seen in Dorizon and in many others in the wards. After the first or epileptoid period is over there can be no doubt that a certain amount of intention pervades and guides the patient's movements. It is noticeable that, during the second period of contortions and violent movements, she never injures herself against the iron rails of her bed, but in her most violent scenes carefully keeps to the mattrass. However, intention on her part by no means indicates simulation, for in all lands, and under the most varying conditions, this period presents exactly the same characteristics. Simulation under such independent conditions would fail to follow in grooves thus similar.

It is now too late in the day to doubt the genuineness of such attacks as we have just described, granting at the same time that that universal element of exaggeration which enters into most of the acts of the hysterical here, also, in hystero-epilepsy, plays its usual, and, it may be added, also its predicable part.

We have thus far followed Dorizon only through a single attack, somewhat in detail, it is true, and with a few explanatory diversions, no more, however, it is hoped, than are necessary to render the nature of the attack clear. The patient had no sooner "came out" of this first seizure than she immediately fell into another, and so on, repeating in one attack after another all the features I have described, until the scene became as monotonous as distressing.

It now remains to record the most interesting, perhaps, certainly the most practical feature of Dorizon's, as well, indeed, as of all similar cases. The attack may be arrested at any period, or phase of a period, in short at any moment, by strong pressure upon the ovary. It is sufficiently remarkable to see violent contortions and the hallucinations of delirium vanish as if by magic, but it is still more remarkable to see the lost consciousness instantly return. This was what was demonstrated to us again and again in Dorizon's case. Taking the moment of the tonic stage (abolition of consciousness, suspended or jerking respiration, rigidity of the body, cyanotic face, etc.), Professor Charcot pressed both hands firmly down into the iliac fossa upon the ovary. Dorizon was at once herself, capable of answering questions intelligently, looking about naturally, and her body without any rigidity. But suddenly the pressure is remitted, and again the poor girl goes on through all the now familiar periods, to use a simile already made use of, like a piece of wound-up automatism, stopped for a moment by the hand, and again moving on when the arresting power is removed. In this same manner these hystero-epileptics will go on through their *series* of attacks, until the hystero-epileptic has exhausted itself, unless they are treated by methodical compression of the ovary.

The question as to which ovary is to be compressed is, of course, decided by examining to see which side of the patient is anæsthetic, for the hemianæsthesia and ovarian hyperæsthesia are on the same side. In the case of Dorizon the right side was perfectly sensible to pain, while on the left no amount of injury, such as pinching and transfixing folds of her skin with large needles, produced the slightest evidence of pain. It was then the left ovary only upon which pressure caused an arrest of attacks.

But the ovary is not the only point at which pressure will cause an arrest of attacks. In most cases, by careful search, a small and circumscribed "hysterogenetic zone" may be found, at which slight excitation will produce, while strong pressure will suspend an attack. The position of this zone is different for different patients, and must be ascertained for each by observation and trial. Frequently it is situated on the back, between the upper part of the shoulder-blades. In Dorizon's case it happens to be just below the outer third of the clavicle. Her attacks were frequently arrested by pressure upon this point as well as upon the ovary.

But however important ovarian pressure may be to the practitioner in enabling him at once to relieve the patient from a given attack, it is time to ask if this measure produces any permanently curative effects upon the disease. According to Professor Charcot, methodically pursued, it lessens the number as well as diminishes the severity of the attacks. It is for this reason that he makes use of the instrument I have already described. There are difficulties, however, in the way of maintaining the pressure continuously which lessen its practical effect as a permanent curative process. For the continued treatment of hystero-epilepsy there are other efficacious remedies. These are ice-bags to the ovary and inhalations of ether and of nitrite of amyl, described at length in the recent second volume of Charcot's "Leçons," etc., and in "Iconographie Photographique," edited by Bourneville and Regnard. We therefore make no further allusion to treatment here.

And at this point we leave this aspect, viz., the "attack" of hystero-epilepsy, reserving for another time certain other features of the disease—a disease certainly comparatively common here in France. It may be asked, Where are our hystero-epileptics in America? To find a thing we must sometimes look for it, and pick it out of confusing surroundings. Its symptom-picture once clear, it springs into view on every hand. It may be that hystero-epilepsy is a rare disease with us. At all events I will not here undertake to answer the question.

And what is the practical bearing of this study, conducted now for several years with so much care by Professor Charcot? The practical value of this work lies in having taken up the hitherto confused story of hystero-epilepsy, and in having brought order out of chaos; in having marshalled into line, under a simple law whose immutability is at once recognizable, the diverse phenomena of the disease; in having shown, in short, that, in accordance with this law, all the symptoms of hystero-epilepsy could be resolved into groups, and that each group was related to another in an invariable order of succession and development. It is this analysis which established, that what was at first glance so evidently epileptic was epileptic only in outer form, just as is the case in certain other diseases of the nervous system, where convulsions are epileptoid without being epileptic.

The term hystero-epilepsy, then, is a misnomer; there is no epilepsy present. The disease is really, as we have already intimated, hysteria major, while the hysteria of every-day practice must be called hysteria minor—the one the fully-developed disease, the other rudimentary. Knowing the completed pattern of a hysteria major, it is easy to fit into their proper places the fragmentary and detached phases of a hysteria minor. Here, then, in this nomenclature—this division of hysteria into major and minor—lies a great advance. Not only has hystero-epilepsy become an intelligible disease, but in becoming hystero major it has thrown a brilliant light upon ordinary hysteria, and rendered its manifold phases clearer to the practising physician.

Very truly yours,
William J. Morton.

Paris, August 7, 1880.

ARMY NEWS.*

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from September 19 to September 25, 1880.

Munn, C. E., Capt. and Asst. Surgeon. To accompany the battalion of the 4th Cavalry, which is relieved from duty with the Ute Expedition, to Fort Garland, Col., and then proceed to and take post at Fort Hays, Kan. S. O. 210, Department of the Missouri, September 21, 1880.

Winne, C. K., Capt. and Asst. Surgeon. Relieved from duty at Fort Brady, Mich., and assigned to duty as Post Surgeon at Fort Schuyler, N. Y. H. S. O. 167, Department of the East, September 21, 1880.

Reed, W., Capt. and Asst. Surgeon. Assigned to duty as Post Surgeon at Fort Ontario, N. Y. S. O. 167, C. S., Department of the East.

Richard, Chas., First Lieut. and Asst. Surgeon. Relieved from duty at Fort Snelling, Minn., and assigned to duty as Post Surgeon at Fort Maginnis, M. T. S. O. 110, Department of Dakota, September 15, 1880.

The "Epizootic" Fever has been prevailing among the horses of Boston.

A CASE OF SUDDEN DEATH DURING ETHER ADMINISTRATION.—The rarity of cases of sudden death during the use of ether, as an anæsthetic, makes the report of the following case, made by Mr. R. N. Hartley in the *Lancet*, of unusual interest. The patient was a gentleman, aged sixty-six, who had complete obstruction of the bowels, probably in the lower part of the descending colon. It was decided that the only hope lay in opening the bowel in the right lumbar region.

Before the operation the patient's pulse was found to be rather quick and small, but not inordinately feeble. The heart was healthy, and there was nothing to contraindicate the use of an anæsthetic. Ether was administered by Clover's smaller inhaler, two ounces being the quantity contained in the ether-chamber. The patient took the anæsthetic without any trouble, and in two minutes was quite under its influence. He was then placed on his left side, with the head lower, and the operation was commenced. The patient was not allowed to become carbonized, and the inhaler was frequently withdrawn. In ten minutes from the beginning of the operation, the pulse beating strongly, the patient vomited a quantity of brownish fluid, smelling of brandy. He then took one deep inspiration, and seemed as if inclined to vomit again; but his head sank bank on the pillow, and he quietly died. Efforts at resuscitation did not avail. He had inhaled a little over an ounce of ether. No post-mortem was made. Mr. Hartley thinks that two circumstances contributed to the fatal result: first, the distention of the bowels with gas, thus perhaps interfering with the action of the diaphragm; second, the undoubted tendency to death from asthenia in cases of abdominal obstruction.

THE DEATH OF PROFESSOR BUHL, whose researches into the histology of tubercle gained him a wide reputation, is announced.

DERMATOLOGY IN AMERICA.—We do not often hear concessions to our pre-eminence in any branch of science from across the ocean. The spontaneous acknowledgment by the *Lancet*, therefore, of the superior standing of dermatology in this country should be gratifying, though it is only just. The history of the rise of American dermatology, as given by Dr. Duhring, is recapitulated, and the good work done by its specialists is commented on. "All this reminds us," it says, "of the need for an examination of the state of things at home, which certainly compares unfavorably with that abroad." The lack of a dermatological society and journal in Great Britain is deplored.

PHOTOGRAPHING THE RETINA OF A MURDERED WOMAN.—An old woman was brutally murdered a short time ago at Sandy Hill, in this state. Not the slightest cue as to who was the perpetrator could be found. As a last resort, the retinæ of the eyes were exposed and photographs taken of them. It is not stated what the result was.

ALLEGED IRREGULARITY OF A MEMBER OF THE RICHMOND COUNTY (N. Y.) MEDICAL SOCIETY.—At the annual meeting of the Richmond County Medical Society, held July 7, 1880, the following resolution was unanimously adopted:

Whereas, Dr. ——, at the meeting of the American Medical Association, on June 4, 1880, offered a resoution impeaching the standing of the Richmond County Medical Society on account of the alleged former irregularity of one of its members; and whereas, this society is in possession, after careful inquiry, of evidence showing that the member referred to has been recognized as in regular professional repute since his graduation, and that his position in this respect was known to Dr. —— at least as long ago as in 1869; therefore,

Resolved, That the above-mentioned resolution, offered by Dr. ——, must have been known by him to be utterly invalid as regards the standing of the Richmond County Medical Society, and could only have been prompted by an intent to injure the character of a physician whose record has been before the profession for many years.

Resolved, That a copy of this resolution be forwarded by the secretary to the principal medical journals.

W. C. WALSER, *Secretary*.

[We omit the name of the gentleman who moved the resolution, in order to divest the question of all personality and narrow it to a mere statement of fact. Besides, the vindication of the character of the society in question rests with the Judicial Council of the American Medical Association, to which body the charges have been referred.—ED.]

DR. F. P. STEPHENS of this city, is the author of the interesting article on the sphygmoscope published in the issue of September 11th.

MUSHROOMS ON THE RED BLOOD-GLOBULES.—The doubts regarding the scientific value of Tanner's fast may now be said to have been eternally set at rest. A distinguished professor, whose reputation as a chemist, etc., is world-wide (*vide* daily press of July last), took some of Tanner's blood just at the close of the fast. Examining it under a microscope, he found certain vegetable fungi growing upon the red corpuscles. These corpuscles were smaller than normal, and, projecting from the surface were numerous little protuberances — the fungous growths. Nearly all the red corpuscles were affected in this novel and unpleasant manner. The white corpuscles, however, were not touched, which showed, we think, an ill-judged discrimination, as they are considered to be fresher, juicier, and without the unpleasant chalybeate taste of the red. However, the facts are as stated, and we have had the pleasure of seeing a woodcut of the whole business.

The theory offered to explain these appearances is that, as the organism became more and more deficient in nutritive supply, a tendency to disintegration set in. But nature, showing here, as ever, her wonderful conservative power, did not allow these animal cells to be decomposed at once. They formed, in their weakness, a suitable food for lower vegetable organisms. These fed upon the red blood-corpuscles, and at the expense of them. At about the fortieth day they had got out in full force, and were having a delicious gory time with Tanner's blood. In a day or two more they would doubtless have eaten the globules all up, and left the plucky faster with nothing but vegetable protoplasm and a few white blood-corpuscles floating through his anatomy.

The above interesting and novel changes are described in a prominent and usually careful scientific journal. The phenomena of crenation were, perhaps, not sufficiently considered by the world-renowned chemist.

COLOR-BLINDNESS AND THE PHYSICAL EXAMINATION OF SEAMEN.—Surgeon-General John B. Hamilton, in a letter to the Secretary of the National Board of Steam Navigation, Capt. B. S. Osbon, gives the following interesting particulars regarding the physical examinations of pilots and other seamen that have so far been made by the Marine Hospital Service :

"Briefly, I may say that up to June 30, 1880, there have been examined by the Marine Hospital medical officers 2,870 pilots and masters, of whom 65 have failed to pass the surgeon, 64 for color-blindness, and 1 because he was too old to see, having what is technically known as "corneal opacity." Of other persons examined, amounting to 838, 43 have been rejected—7 color-blind, 9 heart disease, 6 rupture, 2 consumption, 7 chronic syphilis, 1 Bright's disease, 3 varicocele, 1 hydrocele, and 7 from other causes. Most of these examinations have been from revenue marine vessels. But few merchant vessels have availed themselves of the privilege, although our books show that since 1873 this service has received and treated from merchant vessels 2,731 cases of consumption, 641 of heart disease, 136 of varicose veins, 98 of aneurism, 2,752 of ulcers of the leg, 5,800 of secondary syphilis, 482 of Bright's disease, 30 of cataract, 314 of hernia, 1,335 of stricture, 62 chronic insane, and 133 epileptics—making a total of 14,468 persons physically incapacitated for seafaring pursuits, and represents an almost incalculable loss of time on shipboard, and indirect loss of the shipping interests, to say nothing of those chronic "bummers" discharged with three months' pay in foreign ports. There are two things in which I should like the assistance of your society: one is in the passage of a law for the compulsory physical examination of seamen before shipment, and the other is the establishment of a National Snug Harbor for those worthy seamen and officers who become permanently disabled in the line of duty. This latter institution could be largely supplied by the incurables from the hospitals. Another thing, we need a good hospital in the port of New York. We treated last year 24,780 men, an increase of more than 3,000 over the previous year."

The Board authorized a committee to memorialize Congress for the establishment of a National Snug Harbor.

The Gabble of Science.—The tendency nowadays to bow down to science, and to measure everything by its scientific standing or importance, has a ridiculous side as well as a good one. The London *Times* comments as follows: The popularization of science has its drawbacks, and perhaps not the least of them is the sort of worship, analogous to that of very young ladies for the curate of the parish, which is offered by silly people to those who are—or, more frequently, who are supposed to be—the chief representatives of scientific learning. The absurdities of the so-called æstheticism are not peculiar to gentlemen who lunch upon the sight of a lily, but have their close analogies among those who profess to be scientific. There is a scientific jargon as well as an art jargon, both of them, in the lips of most people, concealing, or it may be even exposing, the most profound ignorance of the respective subjects of discourse. And there is a widely spread want of knowledge that the writer who has most successfully popularized a given question is not of necessity the one who is best acquainted with its depths.

Spontaneous Cure of Pulmonary Consumption.—Dr. Heitler, of Vienna, found in 16,562 autopsies 780 cases of "absolute tubercular patches." Of these, 503 were in men, 277 in women. It is inferred that they represent cases in which the phthisical process spontaneously ceased.

Baltimore as a Medical Centre.—The city of Baltimore has had some very nice things said, and justly, about its prospects as a medical centre. It has of late, however, been receiving sharp criticisms at the hands of a correspondent of the *Cincinnati Lancet and Clinic*. This writer says that the medical profession in Baltimore is not prospering in the same proportion with other things. Its societies are few in numbers and have little enterprise, while, as to the schools, "this great city," he says, "cannot be proud of a single institution where medicine is taught in a thorough and dignified manner. Up to the close of the war medical education here was good; since that time it has been indifferent, and may now be called bad." Describing what he calls "the mysterious management of the medical teaching," he says that the College of Physicians and Surgeons states the following in its catalogue regarding tuition fees: "*Students paying full college fees*, $120; *College fee for privilege students*, $35." The peculiar feature of this is that the *privilege students* are those whose fees are commuted, "in conformity with the usage of the times," and whose names are known only to the Dean.

The same state of things prevails in the medical department of Maryland University, as is shown by its circular. "The fee for attendance on the complete course of lectures is $120. In accordance with a usage, etc., etc., ... such students as are unable to pay full rates are admitted at the charge of $50 for the professors' tickets."

On this the very natural comment is made that after reading these paragraphs no medical student would feel able to pay the full rate; and it may be safely presumed by outsiders that the $120 rate is simply ornamental, and that the regular rate of the colleges is that put down for "privileged students." "My inquiries," adds the correspondent, "so far have not discovered that a chromo, along with the other inducements, is offered to each student, a device which it is not too late for the Baltimore institutions to appropriate."

The *Maryland Medical Journal* denies many of the imputations against the medical standing of Baltimore. We should be glad to learn that something could be said regarding the commutation system of its medical colleges. There was a rumor that it was to be abolished, but the above accounts do not seem like it. If the matter is as represented, the Baltimore fee system needs discussion. If a college charges but a small fee, it ought to say so. We never could see anything very vicious in the small fee system; if students were compelled to have a decent preliminary education, and if they would then be put through a long and thorough course of instruction, there could be no harm from small fees.

Dr. Henri Nachtel, by whose instrumentality the Night Medical Service in this city was established sailed with his family for Paris, on Wednesday September 29th. He had the great satisfaction of seeing, before his departure, the practical working of the system for which he has labored so hard, and for which he has made so many personal sacrifices He will take with him the best wishes of his numerous friends in this city.

Dr. Sigmund, Professor of Syphilis in the University of Vienna, having reached his seventieth year, will retire upon a pension.

The Medical Society of Virginia meets at Danville, Tuesday, October 19, 1880.

Original Lectures.

THE CURE OF CONSTITUTIONAL DISEASES BY THE USE OF GLASSES.

A Clinical Lecture

By D. B. ST. JOHN ROOSA, M.D.,

PROFESSOR OF OPHTHALMOLOGY IN THE UNIVERSITY OF THE CITY OF NEW YORK.

(Reported for The Medical Record.)

Gentlemen:—One of the first lessons a medical man has to learn is not only what he can do, but also what he cannot do. When a physician has acquired the wisdom which will enable him to do nothing when he should do nothing, he is far on the road to knowledge. The tendency among most young practitioners, so far as I know, is to do too much. When an ophthalmic case falls into his hands, unless there has been thorough discipline in a long hospital course, the young practitioner is very apt to put on a shade, a pair of glasses, a blister, a bandage, confine the patient in a dark room, apply nitrate of silver, lower the diet, and so forth. This kind of mistaken practice does much harm, and therefore a great deal of my instruction is an attempt to prevent you from doing too much.

When Donders explained to the profession the great advantage which a large number of people, heretofore without relief for their eyes, could obtain by the use of glasses, he accomplished something for medical science which cannot be overestimated; and to go much farther back than Donders, to the time when an Italian adapted the magnifying power of glass to assist the sight of aged people, we can say that this unknown man did that which made him worthy of a monument and a grateful remembrance. The same may be said of him who suggested giving concave glasses to myopes. That man did a great service to the world. If Gustavus Adolphus had had concave glasses, I think he would have not only won the battle of Lutzen, but also saved his own life; but, as he did not have them, he was unable to distinguish his own colors and became entangled among the Austrians and was killed. His inability to see objects at a distance—and in those days there was no artificial aid to vision—led him to suppose that the enemy were his own men, and the life of a great general was sacrificed.

These three suggestions: that by Donders—glasses for hypermetropia and astigmatism, that of the use of concave glasses for myopic persons, and then that of the Italian of convex glasses for old people, were great deeds, and no words of mine can adequately express their value to the human race. But when, from these great discoveries, we go to the extreme of thinking that glasses can cure general affections, such as chorea and epilepsy, then you may be sure that the wave of medical opinion has gone too far, and that the time for its return has come.

I am led to this kind of an introduction to the subject of the lecture to-day—the cure of constitutional disease by the aid of glasses—by the fact that it is claimed, by one writer at least, that by the aid of prisms and convex glasses very great results may be obtained in the relief of such diseases as chorea, epilepsy, and hystero-epilepsy.

It is claimed that many reflex nervous phenomena are caused by disproportionate power between the external muscles of the eye and the ciliary muscle. I believe in certain reflex nervous phenomena as affecting the nutrition of the eye and vision. I believe, for instance, and I was one of the first to show it in a clear manner, that if a man or woman or child needs spectacles and does not wear them, he or she is very apt to have inflammation of the edges of the lids, which is very intractable unless the error of refraction, the trouble for which the glasses should be worn, is corrected by the use of glasses. *But* I do not believe that all cases of blepharitis are caused by failure to wear glasses. I believe that a great many cases are influenced unfavorably, and that some are *caused* by this trouble. When, however, the theory was advanced that chorea was entirely a reflex phenomenon, I was startled. When the theory was advanced that hypermetropia—especially if complicated by astigmatism, a condition in which there is a congenital shortening of the antero-posterior diameter of the eyeball—if uncorrected, was the cause of a great deal of chorea, and that it could be cured by the aid of convex glasses, I was, I say, startled, and I proceeded with my fellow-practitioners at once to investigate the entire subject. What did we find as the result of that investigation? We found, in the first place, that chorea existed before any one knew sufficient to prescribe glasses to correct hypermetropia; and we found also that it was recovered from before anybody knew that glasses were prescribed for the correction of hypermetropia and astigmatism. Furthermore, we found that quite a proportion of children were born hypermetropic, and yet never had suffered from chorea. We found also that quite a proportion who had chorea did not have hypermetropia. With such facts I think the bottom went out of that theory—for these facts are all upon record—as thoroughly as it ever went out of any tub that was completely demolished. All there was left of this new theory was this, namely—in the treatment of any disease everything which you can do to put the patient in a normal condition, as regards seeing and hearing, or the performance of any function, will contribute in some degree, perhaps, toward recovery. Every man is bound to know all he can concerning his patients. The improper performance of any function may militate against recovery, but one should not hastily argue that chorea is caused by an error of refraction, because such patients are very often hypermetropic, myopic, and astigmatic. The large majority of the world are thus affected, yet cases of chorea are exceptional.

Dr. C. S. Bull, of this city, prepared a paper, showing the conclusions I have already stated, which was published in the Medical Record, after having been read before the New York Medical Journal Association. [See Medical Record, vol. xii., page 339.]

Pursuing this line of investigation, I examined twenty students from this college, who never had had severe inflammation of the eyes, as far as they knew, who had spent their lives in study, but who never had suffered from weakness of vision or asthenopia. I then put them under the influence of the sulphate of atropia, which, as you know, puts the eyes at rest so that no accommodation can be employed, and I found that a very large percentage, all but one or two of them, were hypermetropic. Of course the inference was that if these men, who had lived all their lives with a degree of hypermetropia quite equal to what was said to be able to cause many serious diseases, and yet did not either suffer in their eyes or in their bodily figure from any nervous disease—the inference, I say, was natural that hypermetropia did not necessarily cause these troubles. I should also say that none of these men were short-sighted. They could all read the bottom line of Snellen's test-types at twenty feet.

These observations gave ground for the suspicion that a majority of mankind are either hypermetropic or myopic, and I believe that these results will be obtained by any examination which may be made among the people of any nation. Dr. Ely has extended the same line of observation to very young children, and has found that of those which were not myopic, seventy-one per cent. were hypermetropic. Now, then, should not a man be very sure of his ground when he states that so many evils flow from uncorrected latent hypermetropia? Should he not at least be a little suspicious that hypermetropia is only one of the factors causing these troubles?

These same remarks apply to uncorrected myopia and astigmatism. Their relief by glasses is a great boon, but there is no proof that they often cause serious reflex phenomena, except such as are intimately connected with the eye—blepharitis, headache, and so forth.

If you will study Donders'* cases, you will see that those people who receive the greatest benefit from the use of convex glasses are chiefly those in whom the hypermetropia is so great that it can be readily discovered. In such cases glasses improves the vision at once, and Donders' discovery has done for them what I said at the beginning was of the greatest value, and conferred benefits upon the human race which cannot be easily overestimated. Unfortunately for this country, we might have had the advantage of Donders' discovery years before, had Prof. Dewey's article been published in a medical instead of a chemical journal, for our American professor had fully shown the value of convex glasses in correcting hypermetropia. Donders never made any such claims for convex glasses as have been made by those who cure general disease with them. We find in his work very little indeed about these reflex phenomena which are cured nowadays, or said to be cured by the use of glasses. Mention is made of headache, a constricted feeling about the edges of the lids, watery eyes, photophobia, in short, symptoms which have been grouped under the term asthenopia, but nothing whatever is said relative to the cure of chorea or epilepsy or hystero-epilepsy, or general disease. That was reserved for later investigators.

Since the promulgation of the theory that chorea is caused by an error of refraction, and is cured by wearing glasses, a further step has been taken by its author, Dr. Stevens, of Albany. So far as I can judge from his paper, Dr. Stevens no longer has the faith in the cure of chorea by the use of spherical and cylindrical glasses that he once had, but he now believes that a proper training of the ocular muscles, by means of prisms and tenotomy, will not only cure chorea but also epilepsy. At the late meeting of the Medical Society of the state, this gentleman read a paper, in which he claimed *that functional nervous diseases are beyond any and all other causes dependent on anomalous conditions of the refraction or accommodation of the eyes, or upon imperfect action of the muscles of these organs*.

The cases presented by Dr. Stevens as illustrations of his theories, and which are said to have been cured by glasses, exercise of the ocular muscles, or by division of the recti, are epilepsy, hystero-epilepsy, chorea, intense and long-continued headaches. A course of treatment by means of prisms was said to be often effectual. In case this failed, division of one set or other of the muscles was said to be curative in many cases.

Let us now study for a few minutes together the effect of prismatic glasses when placed before the eye.

These two diagrams* represent a convex and a concave lens. If you divide the convex lens in the middle, you will have two wedge-shaped pieces of glass, or prisms, with their apices forming the outer extremities of the lens. If you divide the concave lens in the same manner, you will have two wedge-shaped pieces of glass, or prisms, with their apices in the centre.

Now remember what a convex lens does. It converges the rays of light in the manner shown in the diagram;* the light is refracted toward the bases of the prisms.

What effect has a concave lens upon rays of light? It disperses them—that is, the rays of light are bent toward the bases of the prisms of which it is made up.

This makes you ready for the experiment which I will perform. I take a colored glass (red), put it before one eye, and then I put a prism, with its base upward, before my other eye, and then I look at the candle, twenty feet distant, and describe what I see. I see a red light above, and I see the actual light below. I have double vision. My prism has bent the rays of light coming from the candle toward its base, and has made an image upon that eye at a different point from that at which the image has been made upon the fellow eye; consequently, instead of having single binocular vision, I have a double image and double vision with two eyes produced by prisms. Now let me reverse the conditions, and place the base of the prism before the internal rectus. I see two images, the red light upon one side and the natural light upon the other. The displacement is to one side, instead of being above or below. By using my external rectus muscle very vigorously, as impelled to by the desire for single vision, I can blend these images.

I place the prism before the opposite eye, and by a strong action of the internal rectus muscle I can again blend the images. A point is reached when I use a very thick prism when the images on the retina are so wide apart, that I cannot blend them with all the power I am able to exert with the rectus muscle.

The eye is turned excessively inward or outward as may be necessary to neutralize the displacement of the retinal image made by the prism. This is what is technically called "overcoming" a prism, and blending the double images caused by it.

What occurs when I blend these images in this manner? This excessive convergence or divergence is of course a squint. If you were to look through the glass prism in front of my eye as I am performing the experiment of blending the images of the light, you would see that my eye was squinting.

The theory of Dr. Stevens is, that if a patient is suffering from persistent headaches, or from nervous phenomena of a vague sort, or from general constitutional disease, such as hysteria, epilepsy, and hystero-epilepsy, he may often be relieved by training of his external muscles by the use of prisms. The experiments I have made show the kind of training the muscles receive. Unless a theory is contrary to all the laws of common sense, it is not scientific to deny the possibility of its truth until it has been tested by the accumulations of facts bearing upon it. I will not, therefore, stigmatize this theory, that serious affections of the general system are caused by a want of co-ordination between the recti and the ciliary muscles, or between the different sets of recti, as an absurd one. But I do not hesitate to say that I believe it to be an untenable one. The author's own cases do not seem to me, so far as I have heard of them and seen them, to sustain his theory. As to my own observations, they are all against the theory that gymnastic exercise of the internal and external recti muscles does very much for asthenopia, except in a very few cases; much less for constitutional disease. Indeed, almost all the oculists of my acquaintance in New York use prisms very little indeed even for the cure of want of power or paralysis of the internal or external recti. Time was when they did, but then their experience has shown that the estimate of their value in local affections was an exaggerated one. But let me recite you a specimen case which I have lately seen, and which induced me to speak to you upon this subject.

---

*Accommodation and Refraction of the Eye.

* A reference was here made to diagrams on the blackboard.

A young woman, æt. 19, was brought to my office a few days ago, on account of a headache, which was said to be constant during the day, but not of sufficient severity to interfere with sleep at night. She was found to be myopic and astigmatic, but the correcting glasses made her vision normal. She was a pale, delicate-looking young person. What do I mean by delicate? A delicate person is one whose muscles are not well developed, who is not capable of continued physical exertion, does not bear extremes of heat or cold well, has a capricious appetite, indigestion upon the slightest provocation, cold hands and feet. This patient had suffered the loss of two members of her family from a disease which seemed, from the history obtained, to be of a tuberculous nature. Her father was a strong, robust man, and exceedingly well. Her mother was said to be strong and vigorous. We examined her vision with the result indicated. We examined her internal recti muscles, and found that she was able to overcome a prism of 30° refractive power at a distance of ten inches.

The prism required by both myself and Dr. Ely, under the same circumstances, was also noted.

Dr. Roosa has the power to overcome a prismof 26°. Dr. Ely can overcome a prism of 24°.

Besides, the external recti muscles of this young woman, which are never so strong as the internal recti in a normal condition, overcame a prism of 18°. Dr. Roosa had the power to overcome a prism of 17°, and Dr. Ely only a prism of 10°. The results of the examination of the muscles of Dr. Ely and myself show about what men can do with their eyes; for we are both well, yet our ocular muscles are not as strong as those of this patient.

The father of this patient is a physician, and he informs me that this headache was attributed to a want of power or of co ordination of the internal recti, and that exercise by means of prisms having been tried in vain, it was now advised that the external recti muscles be cut. Do you think that the appearance or the history of this patient proved that her headache had anything to do with the condition of her eyes? I do not. Her myopia was corrected, and her muscles, as shown by tests, were in as good a condition as those of men who use their eyes constantly. It is not logical, I think, to conclude that her headaches were caused by trouble with her ocular muscles. In my opinion the headache of this young woman depended upon the obvious anæmia and other general conditions favorable to its existence. Fresh air, iron, good food, may do something for her, but glasses will only correct her myopia, and division of the recti will produce double vision. Such an operation on such a case is, in my opinion, an unjustifiable one. She needed no operation. She *did* need red blood-corpuscles, and hence all the oxygen which pure atmospheric air could give her. She *did* need the very best kind of food, carefully chosen and most properly prepared, and she also needed all that a carefully regulated mode of living and exercise could bring to her. Besides, she needed to have her eyes thoroughly let alone; and that is what I meant when I said at the beginning of this lecture, that if man learns when to do nothing he has learned a great deal.

I have seen no case of epilepsy or chorea that are benefited or cured by the use of spectacles or prisms. I have seen several such as the one I have detailed, where they have failed to relieve much less serious diseases. My opinion is that even in the matter of the relief of weak eyes, or what we call asthenopic symptoms, the value of glasses is more circumscribed than was supposed when Donders' discoveries became the common property of the profession. This seems to be the opinion of those who participated in the first triumphs that ophthalmology won, when the ophthalmoscope and the value of correcting glasses were discovered. Now that we have come to the proper estimate of their value in local affections, we are asked to believe that a panacea is found in prisms and division of the external muscles for diseases of the nervous system. I for one cannot accept this new and very meagrely supported doctrine. All the philosophy of disease is against its truth. But before this, for our philosophy may be wrong, the facts are, in my opinion, entirely wanting to sustain such a doctrine.

I believe that when the argument that convex glasses, prisms, and tenotomy, in general disease, has been fairly understood, and been fairly put before the profession, they will see that it is probably not founded upon accurate observations. I do not know that I can add to this general statement. To recapitulate: glasses for the old, as invented by an Italian; for the short-sighted, as invented by an unknown man, and for the young who are hypermetropic, as their use was suggested by Donders, are an inestimable boon; but it remains to be proven that the use of glasses, either convex or prismatic, or division of the external or internal recti muscles, will cure any constitutional affections, such as chorea, epilepsy, and hystero-epilepsy.

Tasteless Cod-liver Oil.—Dr. Pontive recommends the following proceeding to disguise the taste of cod-liver oil. A tablespoonful of the oil is thoroughly mixed with the yolk of an egg and ten drops of spirits of peppermint; then half a glass of sugared water is added, and the whole stirred to make an emulsion. In this way both the taste and odor of the oil are completely disguised, and the patients take the medicine without the least repugnance. The cod-liver oil is also rendered miscible with water in all proportions by this process, and being completely emulsified is more readily absorbed in the alimentary canal.—*La France médicale*, Aug. 22, 1880.

REPORT OF A CASE OF TALIPES EQUINO-VARUS,

Successfully Treated by Continuous Stretching.

By CHARLES F. STILLMAN, M.D.,

NEW YORK.

In a paper read before the Surgical Section of the American Medical Association, at its last meeting, I suggested the use of an adjustable bracket as a curative agent in cases of club-foot which were too much deformed to admit of being placed in an ordinary shoe, and also as a substitute for tenotomy in a great number of cases, believing that a gradual reduction by stretching the contractures in an opposite direction from that in which they had taken place would, in a majority of cases, obviate the necessity of tenotomy, even in those cases where spasm following "point-pressure" upon a stretched tendon was present.

In verification of my assertion at that time, I desire in this paper to report the cure of a case of talipes equino-varus of seventeen years' duration, by the means which I at that time proposed, and which in this paper will be presently detailed.

It was a fortunate circumstance that tenotomy was steadily refused by the parents of the patient during all these years, as it offered a case uncomplicated by the use of the knife for a demonstration of the practicability of the plan proposed, viz., of reducing a foot deformed for so long a time by the simple means of gradual and continuous stretching in the proper direction.

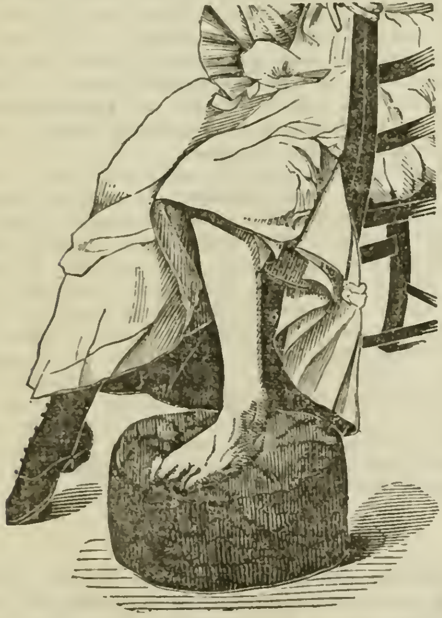

Fig. 1.

Miss Lizzie V——, æt. 19, Plainfield, N. J.; when twenty-two months old had brain fever, which resulted in paralysis of one leg. For several months after her general recovery she could not use the limb, but afterward walked with the assistance of various braces, which were successively abandoned.

An abstract of a letter from her father reads thus: "We were then advised to take her to one of the professors of the Fourteenth Street (New York) Medical College (not now in existence) for treatment, which we did. He gave a lecture on the subject to his pupils, and then desired to operate on her foot; but, adhering to the advice of our family physician never to have her tendons cut, we withdrew at once. The foot continued to grow worse, much deformed, and very weak. About this time I made a metal attachment or side-prong to her shoe, which seemed to be of more benefit than any brace before used, and this she has continued to wear up to the time when she passed under your treatment.

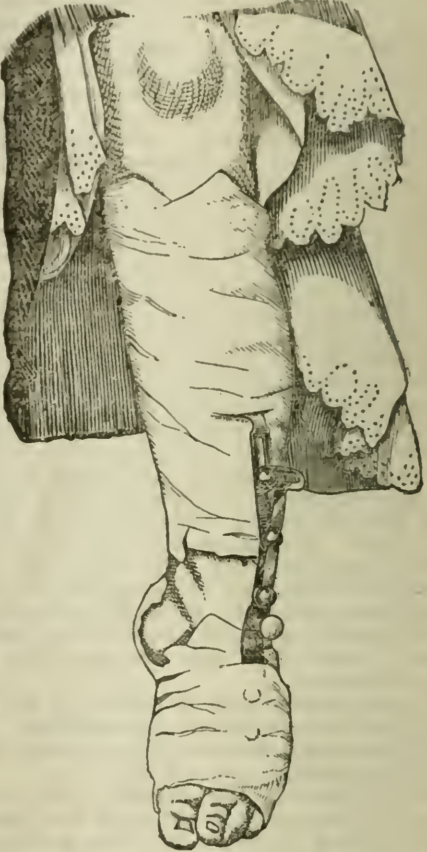

Fig. 2.

"All this time the foot has been growing steadily worse, although she could limp to school, though at times her foot became very painful, owing to the many corns on the side of the foot and ankle on which she walked. We have had the limb examined by many surgeons, all of whom advised the knife, which we have as steadily rejected."

Patient came under treatment July 15, 1880. Her deformity was a club-foot of the equino-varus form, and of seventeen years' duration. After putting the "tendo Achillis" on the stretch, as also the plantar fascia, and pressing with the end of the thumb upon them, reflex spasm was produced—this spasm being considered by those who advocate tenotomy as an indication for that operation.

The foot was atrophied in all its proportions, bent sharply in the middle, and twisted inward and downward. The os calcis was lifted upward by the contracture of the muscles of the calf of the leg, and twisted inward from the vertical line of the leg. The second and third toes overrode the first and fourth, the fifth being turned outward and flattened. The surface of the foot over the instep was prominent and unequal, and indicated displacement of the tarsus. The internal malleolus could not be seen. The external was extremely prominent, and covered with a large callosity. There were also callosities upon the edge of the foot, above the sole. The fissures in the sole were deep, and the whole plantar surface wrinkled and distorted. These wrinkles extended up the internal edge of the foot in great profusion. The leg measured one inch shorter than its fellow, the shortening of the tendo Achillis being one and three-quarter inches. The peronei and tibialis anticus muscles were atrophied, and the entire leg and foot were bluish, heavily veined, and of lowered vitality.

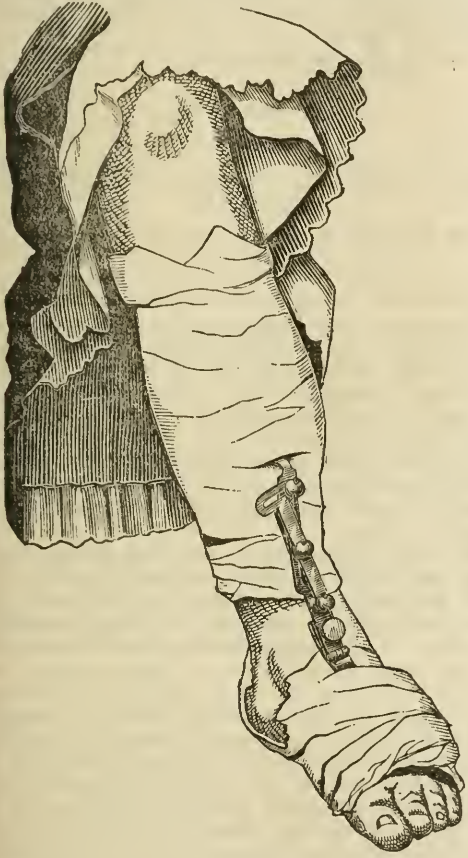

Fig. 3.

Fig. 1 illustrates the condition at its best, the young lady having placed the foot so as to show as little deformity as possible. The foot was placed in my compound bracket, as in Fig 2, by Dr. J. S. Green and myself, and in six weeks the heel was down upon the floor, and the lateral twist of the foot at the medio-tarsal joint corrected (see Fig. 3), so that when the bracket was removed the foot touched the floor normally, the toes being spread out naturally (see Fig. 4). The movements allowed by this compound bracket are two: one being directed to bringing down the heel by a graduated constant stretching of the muscles of the calf, and the other to gradually replace the anterior half of the foot in its proper relations to the posterior, this process proving to be without pain, and it did not confine the patient to the bed or the house, but allowed her to walk upon the foot under treatment.

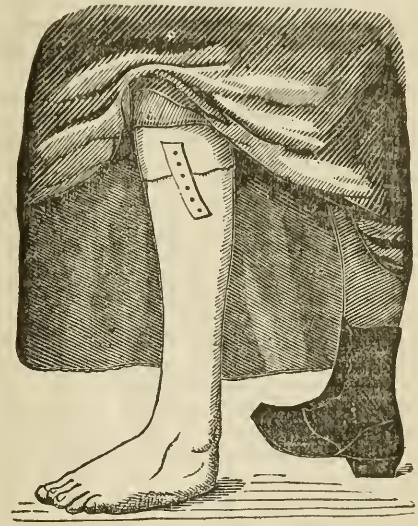

Fig. 4.

One of the satisfactory changes which took place in the condition of the foot above described, during the stretching process, was the improvement in its vitality and nutrition, owing to the re-establishment of the normal relations between the parts of the foot, and between the foot, as a whole, and the leg.

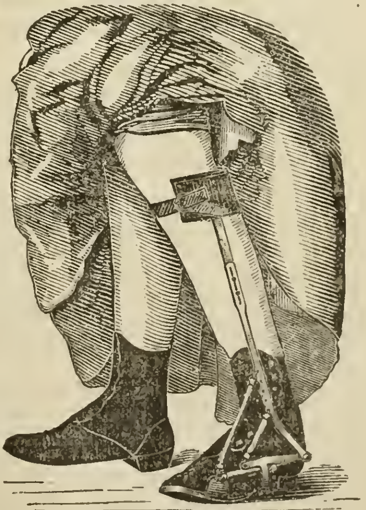

Fig. 5.

At the expiration of six weeks the foot was placed in one of the patient's ordinary shoes and my club-foot *brace* attached (see Fig. 5), and after two weeks' use she reports constant progress, the foot constantly improving in shape and size, and the muscles of the calf increasing in circumference, the actual increase of the calf since the beginning of treatment (exactly two months) being two inches.

My elastic brace is really a combination of the essential principles of the various club-foot shoes, with the essential principles of Barwell's system of elastic muscles. It possesses the very great advantage over Barwell's system of instant removability, being taken off and put on at pleasure, and furnishing at the same time, which Barwell's does not, an articulated, firm support on the outside of the leg, preventing the ankle from turning. It allows the patient to wear a close-fitting, easy shoe, as in a normal foot, and has no constriction or encirclement of the limb or foot other than the shoe, below the girth about the calf, allowing all the natural movements of the foot full play, simply assisting Nature's efforts to guide these in their proper direction. It is light, inexpensive, and lasting, and may be readily attached to any shoe.

The weight of the body is the most powerful agent for good or bad which we have in the treatment of club-foot, and the most important factor also in its production. If the relations of the foot are wrong, the weight of the body tends to increase the deformity; but if, by an elastic retentive apparatus, we can put the foot into its normal relations, the weight of the body tends to press out the angularities and keep it in proper shape by a power just in proportion to the weight of the person and the amount of walking and running that is done. This is one of the best features of my elastic brace, that it not only allows, but actually assists the walking, and consequently is a powerful agent for permanent cure.

The rigid part of the brace has but one *fixed* attachment to the legs below the knee, and that by a girth about the upper part of the calf of the leg, corresponding to the origin of the muscles, and one *movable* attachment by a pivot in the centre of motion of the foot, so that beyond protecting the ankle-joint and stiffening the shoe from the heel to the mediotarsal joint by the arch plate, to which is attached the pivot, these fastenings possess no regulating power over the foot in the least, except when the shoe be attached to the brace by rubber cords.

Now, let us look at the uses of the three elastic cords attached to the club-foot brace.

1. The cord, passing from the extremity of the horizontal strip to the angle of divergence in the vertical strip, controls the extension of the foot at the ankle-joint, and acts against extra contraction of the tendo Achillis.

2. The everting cord, passing from the instep strip to the toe of the shoe opposite the base of the little toe, acts in place of the peroneus brevis, having practically its origin in the immovable girth about the calf and its insertion in the sole considerably anterior to the mediotarsal joint, giving it a tremendous everting power if the girth be fixed immovably, as shown in Figs. 4 and 5.

3. The abducting and rotating cord passes from the base of the little toe to a point in the brace near the girth, supplying the place of the peroneus longus, and acting against the anterior and posterior tibial muscles, whose contraction causes the deformity, and as it is inserted at a point in the sole which is really the apex of the deformity, a power is exerted in exact proportion to the length and strength of the elastic tubing, twisting the anterior half of the foot directly contrary to the tendencies of the contraction.

The pivot insertion below allows the foot to be everted or inverted at will, without in the least impairing the support of the ankle; and any apparatus like those now in use, which allows motion of the foot only upward and downward, does not fulfil the indications.

The phrase "centre of motion of the foot" deserves a little explanation. If you stand upon one foot, and raise the other from the floor sufficiently to suspend it from the hip, rotating it slowly inward and outward, both heel and toe describe arcs of circles of different diameters. Now, while the foot is rotated outward, pass an imaginary line bisecting it longitudinally, and when inward, pass another imaginary line bisecting it, and the point of intersection of these two bisecting lines is the centre of motion of the foot—a line passing through this point and hip-joint being the line of direction of the leg. So that the centre of motion is the proper point to place a pivot if you wish lateral or rotary motion of a foot in the highest degree.

Sept. 15, 1880.

A REPORT OF

THREE TYPICAL CASES OF NEURASTHENIA.

By WILLIAM F. HUTCHINSON, A.M., MD.,

PROVIDENCE, RHODE ISLAND.

(Read before the Rhode Island Medical Society, Sept. 15, 1880.)

Mr. President and Fellows of the Society:—At the request of the presiding officer of this body, I beg leave to present you with a few observations upon that condition of the system which is now generally termed Neurasthenia. The cases upon which these remarks are founded number about forty; but as there is so extreme a similarity between those arising from similar causes, I have concluded to consider but three, each of which is fairly typical of its class.

The term "neurasthenia" was first brought into general use, if, indeed, it was not first coined by my friend, Dr. Beard, of New York, to whom both profession and laity are indebted for a most masterly exposition of its symptomatology and treatment. Its very name—deprivation of nerve strength or force—would seem to be a sufficient definition, but in such an one causation would be entirely neglected. While, then, neurasthenia may co-exist with plasmic change, and be the result thereof, it is not in that connection that it is most frequently observed, or has demanded a specific etiology. It is when there has been no organic decay, no profound disturbance of the peripheral nerves proceeding from central disease, that we most frequently encounter this condition. It is by no means confined to the idle, luxurious classes who have hitherto held almost a monopoly of functional nerve-derangements, but attacks the brain-worker and the hand-toiler alike. Heredity, so far as this identical form of derangement is concerned, can rarely be traced—that is to say, that while the family history of a large majority of sufferers is distinctly nervous. I have not been accustomed to find any trace of the disease itself extending backward. Its rapid increase in frequency and its facility of management have increased almost *pari passu*, and the chief difficulty about it seems the tendency to cavil at its existence, or lightly pass it by as merely a new and fashionable form of hysteria.

In about one-half the cases which have fallen under my observation, the patient has been treated by excellent physicians for grave organic disease, and the real condition neither suspected nor cared for. It would, therefore, seem probable that a more thorough appreciation of the gravity of this affection, and of some of the methods of successful treatment therein, would lead to better results—might at least induce a more careful consideration of its importance.

Some one has said that a proper enjoyment of religion is out of the question when one has dyspepsia. So enjoyment of any of the good things of this life is beyond the reach of an exhausted set of nerves; and if this condition of things be not really disease, it is capable of simulating it with a faithfulness to model that is highly uncomfortable to the sufferer. Practically, whatever interferes with general co-ordination of function constitutes disease; and, if neither pathology nor pathological anatomy have as yet revealed any lesion for the one in question, it does not the less actually confront us. As Putzel says: "It appears to us that undue importance has been hitherto attached to anatomical investigations in the study of the pathology of functional diseases of the nervous system, and too little to the clinical symptoms of these diseases and to their etiology." It is, indeed, to their clinical study that we must turn for results—for cure. It matters little, gentlemen, if we fail to discover the exact morbific lesion in any case under treatment, if such treatment be followed by cure. Do not let me be understood as in any way decrying the brilliant results of late pathological study. I do but claim, in functional nervous derangements, the greater value of clinical observation. Our patients wish simply to get well—to be rid of certain distressing sensations which destroy both usefulness and comfort—and it is that course of study which shows for results practical success, which must obtain in America, when people have very little loose time in which to theorize upon subtle distinctions.

In entering upon the discussion of this subject, I have chosen from my note-book these three cases, which will illustrate, pretty clearly, the marked difference in the three prominent phases of neurasthenia, viz.: cerebral, gastric, and genital.

CASE I.—*Cerebral Neurasthenia.*

A. B——, æt. 36; nativity, Rhode Island; married, four children; height, five feet ten inches; weight, 170 pounds. Father died at 63 years, of consumption, as did also one sister at the age of 30. Has never had any severe illness, except a slight attack of erysipelas in 1870. While serving during the civil war, received a severe blow upon the head with the handle of a pick-axe, which stunned him completely for a short time, but was not sufficiently grave to demand hospital treatment. Some months afterward, while exposed to the sun, was prostrated by the heat, which, however, only kept him off duty for one day. Dates first attack of neurasthenia from 1867, when, in a room full of company, he became very uneasy and was obliged to leave. Shortly afterward, while in a theatre, became faint, but sensation soon passed off. These attacks gradually became more frequent, and once or twice fainted completely away. Finally, he found himself obliged to avoid crowds or crowded places altogether, having a fear of such amounting to terror—anthropophobia. By so doing, he managed to get along comfortably for five years, when, one day, without any previous warning, he felt a sensation of strain in the upper cervical region, followed at once by a difficulty in walking—a decided dragging—first of one foot, then of the other, accompanied by a balancing totter. This soon wore off, and only came on at intervals—finally, altogether disappearing. Has felt a sensation of pressure in back of head, temples, and spine at various times. Has frequent auræ pass down back and legs. His present appearance is that of a strong, healthy man, with nothing abnormal apparent at a glance, except wide dilatation of the pupils. Is easily excited when he cannot sit still, moving limbs restlessly. No difficulty of locomotion, no pain anywhere, and is able to keep track of a large accounting business without trouble. Coming into the city, finds two or three open places which he cannot force himself to cross, and goes a long way around to avoid them—topophobia. Appetite capricious. Sleeps fairly, with constant dreams voluptuous in tendency, but no seminal emissions. Bowels regular. Urine normal. Pulse, 76, thin and nervous. Temperature, at first observation, 101°. Tests for skin sensation and muscle strength gave negative results. Ophthalmoscopic examination revealed nothing abnormal. Tendon reflex perfect—both patellæ and Achillis.

A rigid examination of the chest was likewise negative in results. Both lungs and heart were in normal condition. Electric muscular irritability normal. Upon applying a powerful galvanic current to the spine, two points of irritation were found, the upper over the first lumbar vertebra, and the other over the sacrum.

From the complete absence of all physical signs of organic disease, and the long remissions between attacks of any kind of malaise, and from a general consideration of the case, I placed it under the heading of our first group—cerebral neurasthenia, from its clearly cerebral origin. The only treatment adopted, or that will be advised in the case, is a complete change of residence. Medical treatment, in skilful hands, has failed; and it does not seem to me that much can be done besides assuring the gentleman that he has really no disease whatever, and had better see what a radical change of environment will do.

CASE II.—*Gastric Neurasthenia.*

C. D——, æt. 47; nativity, New York; widower for eleven years; two children; five feet seven inches in height; weight, 126 pounds; in health, 170 pounds; dark complexion, hair, and eyes. Facial expression anxious in the extreme, with dark circles around eyes and deeply corrugated supercilii. General appearance bad—from great weakness and occasional hectic. Has borne the journey from Manchester down very badly, and I was obliged to postpone an examination of the case until he had rested for several days. Father and mother both dead, of intercurrent disease in advanced age. Has lost two half-brothers with consumption, and has a full sister who is excessively nervous. His own children, two sons, are in excellent health, exhibiting, however, strong traits of a nervous diathesis. Has had three attacks of inflammatory rheumatism at intervals of about five years, the last one about five years ago, but knows of no ill results therefrom. Since the last rheumatic attack, has been quite well in every respect until about eighteen months ago. After drinking a large quantity of lager beer, some dozen glasses or more, was attacked with severe nausea and long continued vomiting. This culminated in congestive irritation of the entire digestive apparatus, attended by obstinate constipation. From that time this difficulty, at first acute, gradually assumed a chronic form, and has thus far not been relieved, although short intervals of remission have been observed. Had, at the onset, frequent nocturnal emissions, which have now ceased. Is nervous to a distressing extent. Sheds tears upon any sudden emotion, and finds it impossible to keep still a moment. Some muscle is constantly in motion, the movements closely resembling chorea. Suffers no pain beyond a constant gnawing at pit of stomach. Sleeps tolerably well, with frightful dreams. Mind perfectly clear, and, up to date, has successfully carried on a large mercantile business. Physical condition: extremely emaciated, the skin of the abdomen hanging in folds; bowels flattened and empty; liver normal in size and painless: stomach distended with gas, but presenting no sensitive points to pressure or to percussion; loud borborygmi. Pulse, 68, slow and feeble; temperature, axilla, 99.8°. Forearm muscle test with dynamometer gives irregular, jerky contractions, of one-fifth normal power. Considerable hyperalgesia of skin. Retina and choroid pale, and retinal arteries shrunken. No papillary change. Electric irritability normal, and tendon reflex present. Urine phosphatic.

Patient was referred to me by Dr. Crosby, of New Hampshire, from whose skilful hands he had received unavailing treatment for a year.

Here is a distinct case of nerve-exhaustion dependent upon what is actually starvation, which, however, has not produced, as yet, any appreciable organic change.

CASE III.—*Genital Neurasthenia.*

E. F——, æt. 32; born, Massachusetts; contractor; five feet nine inches in height; weight, 125 pounds; dark complexion, hair, and eyes; married, four children.

Father died four years since with œdema of lungs and mesenteric cancer. Mother living, in good health. One brother died of consumption, and a sister of cerebral dropsy. Has never had any attack of severe illness, although never very strong. Has suffered for seventeen years with habitual constipation, and has always lived in the open air. Pretty regularly, about once a month, has severe nervous headaches, lasting some forty-eight hours. Suffers from pain and weakness over lumbar region. From early manhood has had an enormous sexual appetite, and, being gifted with extraordinary copulative power, has abused the function. His statement is that he cannot recollect a single entire day passing without sexual intercourse for many years—except when, from circumstances, it was impossible—and that the habit is indulged in up to and at the present time. His general aspect is that of a busy, earnest worker, at first glance, apparently healthy. But inspection reveals the usual prominent neurasthenic signs. Pupils widely dilated, uneasiness and general restlessness, cold, clammy hands, and a curious, peering expression are the surface trade-marks visible.

When asked to extend right hand and right forefinger, grows excited and can scarcely do it. When extended, the limb becomes tense, and tremors pass in undulations down its entire length. Temperature, axillæ, 100°. Pulse 100, bounding and thin. Retinal congestion present to slight extent, with incipient optic neuritis. Lungs and heart normal. Urine loaded with urates. Has an indescribable fear of his bed, although sleeps well, with few dreams. Has from five to seven hundred men in charge, and conducts successfully a very important industry. Genital organs of perfect development, the only abnormal appearance being a double varicocele. Has never had any specific disease.

We have here another clear case, so far as causation is concerned, and that causation defines the group to which it belongs—the genital.

Of all the instances that have thus far fallen under my observation there has not been one which could be classified under any other head than one of the above, including in the genital group all those arising from uterine or ovarian derangement. Nor is it likely that any such will present itself from the nature of the case. As to treatment, there is absolutely nothing like a change of environment. In the cerebral group will be found a more general tendency to hopelessness than in the others, which may best be combated by words of kindly encouragement and cheer, for in these cases it is safe to promise, with very considerable certainty, a cure.

In the gastric group a careful attention to diet is the first requisite, and I am in the habit of directing absolute quiet and rapid feeding; in the case mentioned a teaspoonful of liquid food was given every fifteen minutes, night and day, for a week.

In the genital group sudden continence was tried, with a bad result, and it was found necessary to permit a continuance of sexual indulgence, controlling, so far as possible, the morbid tendency thereto.

Medication in all forms amounted to little, if some placebo-like preparation of phosphorus be excepted. This always worked well. I have entirely eschewed the bromides in neurasthenia, finding a depressing effect from their exhibition which is far greater than in organic disease, and far more difficult to rally from.

So with opium and its alkaloids. Patients of this class cannot be trusted with any form thereof, so exceedingly apt are they to acquire the opium-habit from lack of tone in the voluntary processes.

Besides, I have noticed a curious reaction from a narcotic dose of morphia in several cases, wherein the general hyperalgesia, so to speak, of the nervous system was markedly increased, accompanied by choreic muscular contractions.

In place of these drugs I am accustomed to use lactucarium and hops, the sedative effects of which combination are sufficient in the majority of cases.

Alcohol in some form is almost a *sine qua non.* I am well aware that this is a delicate point upon which to touch, but an absolute *noli me tangere* is inconsistent with scientific study. Certain pathologists state that alcohol is never a food; that it is excreted from the human economy unchanged, etc. Others, with equal fidelity to experimental result, are certain that it is absorbed, and is a direct nutritive. With these disputes I have nothing at present to do, but turn again to clinical observation as affording far more reliable data for results than pathology. The plain facts are, that neurasthenic patients gain in nerve-strength and improve in general condition very much faster when a small amount of alcohol is added to their food than without it. And, as cure is the object at which we aim, I always order alcohol, using some form of light wine, and stopping short of an amount sufficient to flush the face. Electricity, in all its forms, is, in many cases, the only actual treatment required, and in all yields invaluable aid.

Central galvanism is employed on alternate days with general faradization, and its administration is followed by exceedingly agreeable nerve-stimulation without subsequent reaction. The galvanic battery used should be a permanent one, of some form of Daniell's cell, as giving a current of low tension and large quantity. Faradization induced from a short coil by a cell of high tension, like the carbon-zinc arrangement of Grenet, is less likely to give good results than that from a long coil, induced by a large Smee or several Daniell's cells.

Change of environment, as said before, is of the utmost importance. New scenes, new surroundings, new associates, with all the subtle influence of change, will often prove potent in effecting a cure when all else fails. Especially when the mind is involved to any extent is a move essential, and, when made, it is well to have it as great and as radical a change as is possible.

Reports of Hospitals.

BELLEVUE HOSPITAL.

Reports of Practice and Peculiarities of Treatment.

TWELVE CASES OF EMPYEMA.

(Reported by William S. Cheesman, M.D., House Physician.)

During my service as house physician at Bellevue Hospital, the following twelve cases of empyema have come under my immediate observation:

1st. Michael B——, blacksmith, æt. 26. The patient was first taken ill twenty-six months ago (from the time of writing) with pain in the left side, cough, and dyspnœa, but was not confined to bed. Two months later he was aspirated; the fluid then drawn, he states, was clear. Within three days he had a chill, followed by fever, and had to take to his bed. On admission, he was emaciated, had pains and much dyspnœa, the left chest being nearly full of pus. Was aspirated on several occasions, and, in all, 137 ounces of pus were thus removed, each time with temporary relief. At last, about one and one-half months after admission, a free opening was made in the left side, between the eighth and ninth ribs, and 200 ounces of pus were evacuated. The cavity was washed out regularly with carbolized water, and the hectic gradually ceased, permitting the patient to do light work about the ward. About six months later, it became necessary to resect a portion of two ribs which had necrosed under the constant contact with pus. This allowed the chest-wall to fall in, partly closing the cavity. The patient improved, and left the hospital, but returned again some three months ago because he was unable to work. The cavity has not closed. The discharge amounts to about five ounces daily. He now has an enlarged liver, and his urine contains albumen and casts; it is supposed that both liver and kidneys are undergoing amyloid changes. He washes out the cavity daily, and is free from hectic, but looks cachectic. The diseased side is much retracted, measuring three inches less than the sound one.

2d. Josephine C——, æt. 33, actress. On admission, the patient stated that she had been well up to three weeks before, when she was taken with sharp pain in the left side; she coughed up mucus and blood, was short of breath, and slept only under the influence of soporifics. It was manifest that no care had been taken of her. Physical examination indicated the presence of fluid in the left chest. The heart was dislocated, and beat just internally to the right nipple. The hypodermic showed the fluid to be pus. Aspiration was performed, and 937 c.c. of pus were withdrawn affording much relief. Six days later, sweating, pain, and dyspnœa returned with the reaccumulating pus, and a free incision was made between the eighth and ninth ribs, twenty ounces of pus being evacuated. Constant drainage was secured by a long rubber tube leading to a vessel containing carbolized water, and placed under the bed. The heart gradually returned to its position, in two days reaching the median line. Sixteen days after the operation, œdema of the lungs set in, which was several times diminished by cups and stimulants, but, finally, the patient succumbed. No autopsy.

3d. James N——, æt. 17. When admitted, this patient was suffering from croupous pneumonia of the lower lobe of the left lung. The attack was severe. the evening temperature being 104° + for four days, and once 105°, the patient delirious much of the time, and a petechial eruption appearing over the thighs and abdomen. On the seventh day of the disease, the râle redux was heard. The temperature did not fall with that sudden plunge characteristic of croupous pneumonia, but dropped gradually, reaching 100° on the tenth day. It never fell below this. Soon afterward the patient began to complain of pain in the left side, and the temperature began to rise again gradually. Eleven days after the râle redux had been heard there were signs of fluid in the left chest, but the hypodermic did not find it till two days later. It then drew pus. The patient was aspirated, and 340 c.c. of creamy pus were evacuated. Temperature range elevated. One month after the presence of fluid was first suspected a free incision was made, and two quarts of pus let out. Drainage-tube inserted. Washed with carbolized water twice a day. Patient slowly improved; in a month could sit up, and in two months was walking about the ward. Three months later, the affected side measured two and one-quarter inches less than the sound side. It is now thirteen months since the side was opened. The patient is in very fair condition, can work, and has good appetite. But a sinus remains which discharges about two drachms a day; the left side is much retracted, and the patient deformed thereby.

4th. Geo. A——, auctioneer, æt. 39. For about six months the patient had been losing strength and coughing, and had sought relief in drink. Three days before admission, while cutting grass with a sickle, he was seized with a sudden pain in the left side, whereby he was rendered helpless, and had to be put to bed by friends. On admission his temperature was 104°, and all over his left chest were heard metallic, amphoric breathing and voice sounds, with the metallic tinkle and splashing sounds on succussion. The side was resonant, did not bulge, fremitus was unaffected, and the heart was displaced to the right. Hydropneumothorax due to phthisical perforation of the lung, was diagnosed. Kept in bed, the patient rapidly improved. The fluid in his chest did not increase. He was able after a time to sit up, though suffering considerably from pain and dyspnœa. He had most comfort when lying on his stomach. It was not until three months after admission that the fluid in the side increased and aspiration became necessary. Then 200 c.c. *serous* fluid were withdrawn. Twelve days later he was again aspirated, and 840 c.c. *clear serum* drawn off. Nine days later aspirated again, and fifty-three ounces of a turbid fluid containing much pus were evacuated. Seven days after, again aspirated, and 360 c.c. *pus* removed. Five days later a free incision was was made and the chest washed out, but in two weeks the patient died exhausted. No autopsy.

5th. James H——, æt. 65. When admitted to the hospital the patient presented the physical indications of fluid in the left pleura and consolidation of the right apex. It was a long time before the fluid was reached by the hypodermic and shown to be pus, and the patient was then much weakened by hectic. The empyema was encapsulated, and when opened discharged about twelve ounces pus. The patient did not long survive the operation. At the autopsy there were found phthisis of the right apex, and an empty cavity bounded by adhesions in the left pleura.

6th. Ransom S——, æt. 12. When admitted, this patient had been ill about two months with pain in the right side, fever, cough, and sweats. Two weeks after he was first taken he began to cough up blood and pus, which soon became offensive. On admission he looked very thin and worn. Temperature range high. The physical signs indicated fluid in the right chest, which, when drawn by the hypodermic, was very fetid pus. He was continually expectorating a similarly offensive sputum. The diagnosis of empyema with perforation of the lung was made, and in view of his miserable condition it was decided to open the chest and put a stop to further purulent absorption. This was done two days later, but the empyema being encapsulated, and the knife introduced a little outside of the encapsulation, it became necessary to break down adhesions to reach the pus, which was accomplished with some difficulty. The cavity was thoroughly cleansed and the expectoration ceased, but unfortunately erysipelas involving the tissues of the back set in, and the patient died exhausted four days after admission. The experience derived from the case led to the adoption, in all subsequent operations, of the rule to cut only where the hypodermic had first drawn pus.

7th. Lizzie M——, æt. 29. This patient was admitted with acute articular rheumatism, which was relieved by salicylic acid. Within a fortnight a complicating pleurisy developed in the left side, and caused so much pain and dyspnœa that it was necessary to aspirate, clear serum being on three occasions withdrawn. In three weeks the inflammation extended to the right pleura. Aspiration was again necessary, and both pleura were relieved—the left, of twenty-five ounces purulent fluid (not clear pus); the right, of eight ounces sero-sanguineous fluid. The next day twenty ounces were drawn from both sides. Two weeks later it was discovered, by the use of the hypodermic, that there existed in the left pleura *two* encysted collections of fluid, from the upper one of which the needle, introduced in the axilla, drew *clear serum*, and from the lower, *pus*. The lower one was emptied of twenty-eight ounces, and subsequently of sixty-three ounces and twenty ounces of pus, the collection in the upper sac remaining *in statu quo*. Meanwhile the pleurisy of the right side receded, and gave no further trouble. But the urine contained albumen and casts, and there was great anasarca of the extremities. Two and a half months after her admission, the patient submitted to the radical operation, and a large amount of pus was evacuated by a free incision into the lower encapsulation. A portion of rib necrosed, and some burrowing of pus ensued, so that it became necessary to make a counter-opening under the scapula. From this time the patient slowly but steadily improved, her temperature range gradually fell, and the œdema of the feet and legs disappeared.

She now walks about the ward and grounds. The sinus in the chest admits only a small tube, and discharges about half an ounce a day. The temperature ranges below 100°. There is no retraction of the side. The upper serous encapsulation has disappeared. A small piece of dead bone came out of the wound some time since.

8th. Richard B——, æt. 32. When admitted, the patient was suffering from alcoholic pneumonia. His temperature at the end of the disease did not drop suddenly, but gradually. He seemed, however, to be making a good convalescence till two weeks after admission, when his temperature suddenly shot up, and he began to complain again of pain in the affected side. Signs of fluid developed there, and turbid serum was drawn by the hypodermic two days later. Twelve days later still the patient seemed much worse; *pus* drawn. An attempted aspiration wounded the lung, causing hæmoptysis, but did no further harm. On the contrary, the patient began slowly to improve, although hectic and cough persisted. The signs of fluid diminished, leaving behind those of consolidation over most of the back. No fluid was ever drawn again, though the hypodermic was repeatedly introduced. Finally, the only signs remaining were those of thickened pleura. Five months after admission patient was discharged quite strong and well, but with a very perceptible retraction of the side.

9th. Mary J——, æt. 26. The patient stated that a month before admission she had a left pleurisy, with effusion, which, after two aspirations, became purulent. When admitted, she seemed in fairly good condition, without hectic, and eating well. She was aspirated, and about two pints of pus were withdrawn. It was decided best to make free incision at once, before her strength should be sapped by hectic. This was done a week after her admission. Two incisions were made, one in the fifth, the other in the seventh interspace, just anteriorly to the axillary line, and a drainage-tube was passed from one to the other, and the two protruding ends tied together. After the operation, the patient bled from the interior of the chest, *not* from the incisions. It was supposed that the hemorrhage came from some organized adhesions, ruptured by the passage of the drainage-tube. Tannic acid injected into the chest finally stopped the bleeding, but the patient was left pulseless, and vomited everything given her. The next day transfusion of blood was performed by Dr. Polk, and about one ounce of saline solution and three ounces of blood from a strong man were injected into her median basilic vein. Aveling's apparatus was employed, and gave poor satisfaction. Improvement followed, however, and she was able to take food. For some days clots of blood were washed out of the chest by the cleansing solution. Gradual recovery from the collapse followed. Her temperature curve, hectic. For about six weeks she held her own, but, though the chest was washed out sometimes thrice daily, hectic continued. She became emaciated, bed-sores formed, and she finally died of œdema of the sound lung.

10th. Christopher W——, æt. 50. Was admitted with subacute pleurisy on the left side. The effusion was shown by hypodermic to be serous. In the course of a few days it became purulent. On three or four occasions the chest was aspirated, and two or three pints of pus were drawn off each time. The empyema seemed to be encapsulated. Emaciation set in, and the temperature range ran high. The radical operation was proposed, and the patient consulted; but just then he began to feel better and his temperature to fall. Operative interference was delayed. He improved steadily, and in a month after admission no pus could be obtained from the chest, though the physical signs seemed to indicate either the presence of fluid or a very thick pleura. The patient left the hospital six weeks after admission, feeling well. He returned in a fortnight for examination, and all that could be found was an area of dulness, with absence of voice and respiratory murmur over the site of the empyema. He said he was perfectly well and able to work.

11th. Thos. B., æt. 50. The patient stated that he had had a cough for some years; yet he looked strong and healthy. About a week before admission he was exposed to cold, and had had pain in the left side and increase of cough ever since. Examination revealed a dry pleurisy on the left side, and a few râles over the lower part of the right lung. Two days after there was an effusion in the left pleura, which the hypodermic showed to be serous. Two days later still the patient began, all at once, to spit up great quantities of fetid material, and fetid pus was drawn from the left chest. Temperature range high. After aspiration of twelve ounces of pus, the signs of pneumothorax were obtained. So that it seemed certain that in some way perforation of the lung had occurred, and air had gained access to the pleuritic effusion, decomposition following; or the effusion had become gangrenous, and eroded the pulmonary pleura. The empyema was encapsulated. Patient was twice aspirated after this, and three weeks after admission an incision was made into the empyema, and drainage secured. The carbolized injection often set up a cough, during which some of it would be expectorated. Soon after the operation, phthisis, starting from the area of râles above mentioned, began rapidly to invade the right lung. The patient died two weeks after the chest had been opened. Phthisis was looked upon as the immediate cause of his death.

12th. Mary H., æt. 4½ years. The child's sickness began with restlessness, followed by cough, dyspnœa, and pain in the right side. The physical signs seemed, on the whole, to point to croupous pneumonia, though the percussion-note was absolutely *flat* over the lower half of the thorax behind. It was not until the fourth day after her admission that the physical signs unmistakably denoted fluid, which was drawn by the hypodermic, and shown to be thick with pus. Temperature high. The patient was aspirated on the seventh day of her illness, and twelve ounces of creamy pus removed. She suffered much from shock, but recovered in five or six hours. The hole made by the aspirator-needle allowed some of the pus to escape into the tissues of the back, and, as the mother refused to allow any further operation, it burrowed. The child passed into stupor on the sixteenth day of her disease. An incision was made then, the mother consenting when hope was gone, but the patient survived only a few moments. No autopsy.

It is interesting to observe that most (all but four, certainly) of these cases began as pleurisy with serous effusion, and that in two, at least, the empyema was a sequel of croupous pneumonia. In half the cases the whole pleural cavity was involved; in half the empyema was encapsulated. Seven cases died, all of whom had been cut; but in two (6, 11) death was due to complications, while in two others (4 and 5) the empyema was a concomitant of conditions already fatal in their tendencies. So that in only three cases (2, 9, 12) can death be attributed to empyema alone. Five cases recovered; two (8 and 10) *without* operation, the pus having been absorbed, or having undergone calcareous or other changes. In the one case (8) retraction of the side remained; in the other (10) none. Of the three others who got well after operation, one (7) recovered with only a sinus; one (3) with a sinus and retraction of the side, and one (1) with sinus, retraction, and probably waxy liver and kidneys.

In considering these results we are not led to regard incision for empyema as one of the triumphs of surgery. Leaving out those fatal cases in which empyema was complicated with phthisis, erysipelas, etc. (4, 5, 6, 11), three remain (2, 9, 12) whose lives the operation failed to save (though one—12—was in *articulo mortis* when it was done). In Case 9 the operation seemed to have hastened the patient's death. Of those who recovered (1, 3, 7) after operation, all have sinuses, and two are deformed.

Perhaps it is not unfair to hope that the results might have been better had the patients not been operated on in a large public hospital, where the food is poor, and where nosocomial malaria abounds.

Progress of Medical Science.

THE PATHOLOGICAL HISTOLOGY OF ACUTE PAROTITIS.—Dr. Wendt, of New York, has published a contribution to the minute anatomy of this disease, based upon the study of an inflamed gland. He found that the morbid process passed through several stages, with the ultimate possibility of complete restoration of the gland to its normal condition. The first stage of the disease was one of congestive hyperæmia, the arterioles and capillaries being packed with blood-elements. Then came a stage of exudation, accompanied with the emigration of many leucocytes. Rupture of capillaries occurred simultaneously with this action. Then followed a period of epithelial hypertrophy and hyperplasia, caused, according to the author, by the stimulus of excessive blood-supply to its secreting acini. Soon, however, the epithelial cells underwent cloudy swelling, and then fatty degeneration. The products of this process accumulated in the meshes of the interstitial connective tissue. Active proliferation of the secreting cells went on simultaneously with these morbid changes. For this reason the writer expresses his belief in the power of complete glandular restoration. The question whether the disease was a case of mumps, or an instance of so-called secondary parotitis was left undecided.—*The New York Med. Journal*, September, 1880.

THE LOW ORGANISMS OF INDURATED CHANCRE.—The researches of Prof. Klebs with regard to indurated chancre failed to bring to light the presence of foreign organisms in addition to certain histological changes which are characteristic elements of the lesion. Pisarewski recently undertook the renewed investigation of this matter. At the instance of Prof. Grube, of Charkow, he examined four specific sores immediately after their excision. The specimens were hardened in Müller's fluid and alcohol. The characteristic leucocyte infiltration of the connective tissue was found in all the specimens. The newly formed blood-vessels of the syphilitic induration were remarkable for the thickness of their walls. But Pisarewski found in addition to these changes a new feature of the lesion. The entire indurated nodule appeared to be traversed by numerous canals and cavities, the former, as a rule, pursuing their course in the direction of the blood-vessels. These canals, however, exceeded the blood-vessels in the size of their lamina. They lacked separate walls, but showed an endothelial lining. For this reason the author regarded them as lymphatic channels. Some were found to be empty, others contained lymphoid corpuscles, and still others were filled with a peculiar, finely granular substance. The latter consisted of round granules, imbedded in a transparent, homogeneous connective matter. Great uniformity of size and shape was noted in connection with these granules. They were found grouped together in nests, and received interpretation as low organisms called zoöglœa. The action of coloring matters and chemical agents upon these bodies justified this interpretation. They remained unchanged after boiling in equal parts of alcohol and ether; glacial acetic acid, or caustic potash solution had no effect on their appearance beyond rendering them more conspicuous in the changed surrounding tissues. Different other reactions all pointed to the vegetable nature of these low organisms.—*Centralbl. für Chir.*, Aug. 7, 1880.

A Positive Sign of Pregnancy during the First Three Months.—In a paper read before the Detroit Academy of Medicine, Dr. J. H. Carstens mentioned a positive sign of pregnancy on which he had always relied, and which had never failed in his experience to enable him to diagnosticate this condition. He had been under the impression that it was a new, not hitherto described sign; but, looking over the literature of the subject, he found that it had been mentioned years ago by Jacquemier and others. It seemed, however, to have fallen into oblivion, and was not mentioned in the ordinary text-books. He referred to the color of the mucous membrane of the vagina and cervix uteri. This he always found of a purplish blue, or rather deep violet hue, in pregnant women, and he depended on this peculiar color in making a diagnosis of pregnancy in the first, second, and third months. He said that it had never failed, and that it was not produced by any pathological condition. The different colors produced by uterine diseases could not be mistaken for this pathognomonic violet hue. He had often called the attention of students to this sign. It had been claimed by some that this color of the mucous membrane was found in various pathological states. He claimed that the discoloration in such cases was different from that found during pregnancy. It was more blue and scarlet, mixed or mottled, nor was the peculiar soft, velvety condition of the membrane present. He simply called it violet, and said that it must be seen, and then would never be forgotten. It was probably caused by engorgement of the veins. All he asked was that this sign be again looked for and submitted to a rigid investigation, and he was sure the verdict would be that it was the only sure sign we had at present to diagnosticate pregnancy from the first few weeks up to the fourth month.—*The Detroit Lancet*, September, 1880.

Rupture of Axillary Artery during Reduction of Luxation of the Humerus—Diffuse Traumatic Aneurism—Amputation at Shoulder-Joint—Death.—Rupture of the axillary artery, associated with simple dislocation of the humerus, or occurring during the reduction, is an extremely serious accident, though, happily, rare. Mr. Bellamy, of Charing Cross Hospital, reports a case in the *London Lancet*, August 14, 1880, where, if the statement of the patient may be trusted, the rupture of the axillary artery occurred during the reduction. Unfortunately, the mode of reduction is not stated. Patient, male, æt. 55, gave the following history previous to admission to the Charing Cross: "Dislocated his right humerus on December 19, 1879, and the following month the house surgeon of a large metropolitan hospital attempted reduction under an anæsthetic, but failed. In the next attempt the patient stated that he immediately became aware of a swelling in the armpit. A fortnight after this he was discharged. He had lost sensation since the time of the last attempt. Three weeks after he left the hospital a little bright blood oozed through the skin, and on July 30th he had more severe hemorrhage, losing about four ounces of arterial blood, and then the bleeding ceased." Upon examination, a tumor was found situated in the region of the right shoulder; the walls were very tense and pulsating; the clavicle was distinct and not involved. The pulsation was best felt at the posterior part of the axilla. The arm below was much swollen and waxy; no pulse could be felt at the wrist. At the lower part of the tumor, in the axilla, the skin was dark and sloughy, from which flowed a watery discharge. The tumor was not distinctly circumscribed at its lower margin, and was about as large as a man's head. Patient was anxious in appearance, and had been rapidly losing health since the appearance of the tumor. He had had no attacks of syncope or breathlessness, and the face was not markedly blanched. Pulse 96, respiration 18. Conjunctiva and mucous membrane pale and anæmic. Had slight cough and watery expectoration. In consultation it was determined to amputate through the shoulder-joint. This was done by commencing with an anterior flap from without, and *not* transfixion. Although the subclavian artery was most efficiently compressed, the hemorrhage on the first sweep of the knife was terrific, the blood coming from the tense sac and from the enlarged vessels behind and below. The second or posterior flap was cut after disarticulation, in a few seconds, and some pounds of clot and organized lymph were removed. The main trunk, as far as its topographical position should have been, was not recognizable. There was a hard, cartilaginous-like tube on the wall of the thorax, throwing a fearful jet of blood, and which, notwithstanding the pressure on the subclavian artery, was secured after great difficulty. After all bleeding-points had been secured, the flaps were adjusted and the patient removed to bed. Unfortunately, he never rallied, and about an hour afterward died. Most of the cases of rupture of the axillary artery during the attempts at reduction have been in dislocation of some weeks' duration. Indeed, it is probable that the rupture of the artery is due to laceration of the adhesions formed around the displaced bone in the neighborhood of the vessels. In the case just quoted no attempt at reduction seems to have been made for at least six weeks. In that time firm adhesions had doubtless formed. In one case in which dislocation of the humerus was complicated by diffuse traumatic axillary aneurism, Mr. R. Adams, of Charing Cross Hospital, reduced the dislocation, and then ligatured the subclavian artery, and the patient recovered.

A Case of Quassia-Poisoning.—Mr. D. T. Reckitt, of the Newark Hospital, England, reports in the *London Lancet*, August 14, 1880, a case of poisoning by the concentrated infusion of quassia, which was given by mistake for the simple infusion. Patient, girl aged four years; had for several weeks suffered from prolapsus recti after action of the bowels. She had very frequent desire to go to stool, and remained sometimes half an hour on the seat, straining violently. Suspecting that ascarides were the cause of the prolapsus, the nurse was ordered at 1.30 P.M. to give an injection of six ounces of simple infusion of quassia. With the exception of a tablespoonful, all the injection was retained, and the child taken away. At 3 P.M. the mother returned, saying that the child was only just alive; that in taking it from the hospital it reeled very much, as if tipsy, and that she was obliged to carry it to a temporary lodging. Mr. Reckitt visited it at once, and found it in an alarming condition. It was ghastly pale, the lips were bloodless, the head thrown back, the surface cold, eyes closed and pupils contracted, with no action to light; respiration inaudible, and the pulse not to be felt. It was quite unconscious. The feet were placed in very hot water, which immediately roused the child with a violent scream. Some strong brandy and water was given, and swallowed with difficulty; but the pulse returned. The child was kept roused by having the feet placed occasionally in hot water and mustard cataplasms applied to both calves. There seemed to be a strong desire to sleep, when the pulse became much slower and more feeble; so the feet were again put into hot water, and small, but strong doses of brandy were given internally. After an hour and a half the child vomited once, and then seemed a little better, but continued unconscious. Half a drachm of ether, one drachm of compound spirits of ammonia, and half an ounce of brandy, diluted with warm water, were injected into the rectum, and retained by means of the finger applied to the anus. This acted most favorably, for the color returned to the lips and face, the surface became warm, and the breathing and the pulse more natural. During all this time, except when allowed to sleep, it moaned very much. The color, respiration, and pulse being much improved, the child was allowed to sleep. At 6 P.M. the child was aroused, and a little brandy was given. At 6.30 P.M. it was conscious, and looked quite well, though sleepy. Some cold milk was ordered. The quassia injection did not act as a purgative, the bowels not having been moved since its visit to the hospital.

Spontaneous Gangrene due to Thrombosis of Popliteal Arteries—the Result, probably, of Malaria.—Spontaneous gangrene is sufficiently rare, especially in a young child, to deserve a record. The extensive character of the mortification and its somewhat protracted course also add to the interest of a case reported by Dr. J. H. Pooley, of Columbus, Ohio, in the August number of the *Virginia Medical Monthly*. The gangrene was due to thrombosis of the popliteal arteries, the result, probably, of malaria. Patient, female, æt. seven years; had always been well and hearty. On December 5, 1879, she was taken with a chill, followed by fever and headache, which subsided after a short time. During the succeeding three or four days she had chills or chilly sensations at irregular intervals, and more or less continuous fever. She complained of headache, swelling and stiffness of the knee, inability to go up and down stairs, followed by a sense of tingling, and later by decided pain in the legs. Just one week from her first chill, a discoloration made its appearance on the dorsum of each foot, and extended up and around the legs as far as the knee on the right side; on the left, to some distance above the joint. The color, at first a purple mottling, soon became uniform, and exactly resembled the hue of a negro's skin. Her condition two weeks from the beginning of the attack was as follows: pulse, 130, feeble and irregular; temperature, 104°; respirations, 50; complained of severe shooting pains in the legs, and pain in the back. Both legs discolored and of icy coldness; toes of both feet dry, hard, shrivelled, and immovable, and entirely devoid of sensation. There was mobility at the ankle-joints, and the sensation was only partially abolished from the ankles to the knees. Under a tonic course of iron, quinine, whiskey, eggs, milk, cream, and a plentiful supply of lemons, her general condition improved very much. When Dr. Pooley saw the patient in consultation, January 1, 1880, there was a perceptible failure of the vital powers. Temperature, 105°; pulse, 130; respirations, 30 per minute. No lesions of either heart or lungs. Never had rheumatism—indeed, nothing except mild attacks of ague—the whole region in which she lived being decidedly malarious. On examining the limbs, Dr. Pooley found the gangrene had extended above the knee on both sides, a little higher on the left than on the right. The toes were quite black, and dry, and hard; above the feet the color was that of a negro, which, at this age and in these parts, is not quite black. Over most of the surface the skin was soft and supple; there were, however, large patches where it had undergone parchment induration. At the upper limit of the mortification there was, on both sides, an irregular, shallow gutter of demarcation filled with stinking ichor, but no inflammatory redness or swelling above it. Her condition gradually grew worse, and she died six weeks from the date of the initial chill.

Autopsy.—Examination of the limbs only was permitted. Sloughing at the line of demarcation had become quite extensive, almost entirely encircling both thighs, with large collections of pus in the popliteal spaces, the arteries alone resisting the general destruction. The dissection was begun in the upper third of the thighs, tracing the arteries until they divided into the peroneal and posterior tibial. An occlusion by a firm thrombus was found in each popliteal, including all that portion between the superior and inferior articular arteries. The cord-like feeling of the vessel extended farther up in the left leg than in the right. The arteries below the point indicated were empty. The integument of the legs was universally hard and brawny; the muscles were in a state of perfect preservation, and of a red color—a remarkable circumstance, when we take into consideration the fact that no blood, or, at least, very little, could have reached the parts for five weeks.

Cæsarean Section on a Dwarf.—The operation of Cæsarean section was successfully performed upon a dwarf, Mrs. Wm. Burnell, in Philadelphia, recently. The infant was doing well, and the mother was in a fair way to recover at last accounts. The dwarf is thirty-two years old, and forty-two inches high. Her father was a dwarf, about the same size as herself, while her mother, who died when she was a baby, was a woman of ordinary size. About nine months ago she married William Burnell, a negro minstrel, then connected with the same show. Mr. Burnell is not a dwarf, but a full-grown man. Such marriages are unequal to the last degree, and ought not to be allowed in civilized and presumably intelligent communities.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, October 9, 1880.

THE MEDICAL REGISTRATION LAW.

We are hardly surprised to learn that quite a number of physicians practising in this state are still unregistered. That this is due in the main to negligence, or to a failure to understand the true import of the law, is hardly to be doubted. That neither of these excuses will avail anything will be quite apparent in case of complaint made against any unregistered physician. While the larger number of medical men who have failed to comply with the provisions of the law may be looked upon as passive opposers of the latter, there are not a few who are willing, on one plea or other, to interfere with its enforcement by refusing to register. There are always martyrs to every good cause, and it will do no harm to kindle some fires which may serve to light up the darker places in the minds of others. As we have remarked on a previous occasion, the law regulating the licensing of practising physicians in this state is singularly free from even technical errors. All the objections to its enforcement were carefully considered beforehand, and every possible provision made against dodging any portion of its letter or spirit. As it stands at present, it is the most perfect one of its sort, consistent, legal, and practicable, and not to be trifled with on any mistaken idea of its constitutionality, or any plea that its penalties are not explicit, or that they cannot be legally enforced. The only serious question of constitutionality of the law is that which provides for the endorsement of diplomas from without the state before the new citizen can be allowed to practise in this Commonwealth. It must be remembered that each state has a constitutional right to make laws for its own protection, and in order to do so it has also the right to insist upon the necessary guarantees from such as may be subject to their provisions. From such a standpoint, the state, for instance, has just as much right to insist that a diploma from outside should be countersigned, as that the health officer of the port has a right to refuse entrance into our port to any one not having a clean bill of health. Each state is competent to make its own laws for regulating the practice of medicine, and if it chooses, it can insist upon having the said laws enforced. In cases of difference of opinion regarding the constitutional right so to do, the safety of the state can be very easily offset against the claims of any individual not complying with the laws of said state. Laws founded upon similar principles are in force in other states, and are duly respected. Why any exception should be made in this respect regarding the registry law, it is not easy to see. In any event it will be safe to assume that if the present law is unconstitutional it will be useless to regulate the practice of medicine by any practicable law whatsoever, and impossible to prevent any quack, foreign or domestic, from practising in any portion of the Union in which he may prefer to reside.

The countersigning of diplomas that are granted outside the state does not appear to be very well understood; at least we should so judge from the fact that some gentlemen who have been practising here for the past ten years have actually taken their diplomas of neighboring states to the college, and paid the fee for endorsement of the same before they believed themselves entitled to register.

The truth is, that every medical man who came into the state before the first of October, with a diploma from outside the state, was, up to that time, "lawfully engaged in the practice of physic," and as such the law merely requires that he shall register. If he comes into the state after that time, his diploma must be duly approved, as aforesaid, before he can be licensed.

Another objection to the practical working of this law has been urged with a very amusing show of stupidity. One of the leading dailies very gravely suggests that now that the first of October is passed, there is no section in the law which provides for the registration of such physicians as are now practising and who have not yet complied with the law. The possibility of such a proposition having any foundation in fact, is an absurdity on its face. The law explicitly says that all lawfully engaged in the practice of medicine shall register, in accordance with the provisions already stated, before October 1st. Up to that time they could practise medicine as unregistered physicians without incurring a penalty. After that time they are practising medicine illegally, and are liable, on complaint, for so doing, to the specified fines. A physician who delays does so at his peril, and renders himself liable for a fine for every patient he may see. The object of fixing the 1st of October as the day was evidently to mark a convenient period of time when the law should go in force with all its privileges and penalties. Simply his and nothing more. It would be preposterous to uppose that any law could be enacted, with penalties o be enforced, and yet no opportunities be afforded o escape from said penalties.

As can be seen very plainly, there is no provision gainst registering at any time, but much the safer and etter way would have been to have done so before the ime expired, and when delinquents were not liable to enalties. In other words, no practising physician vho is not at present registered is safe from the viles of any informer who may desire to obtain half he fine inflicted.

In conclusion, we say that if there is to be any pen opposition to the present law, it should, least f all, come from members of the medical profession. The latter owe it to themselves, individually nd collectively, to make it a practical success, as far s such can be possible. To this end it is perhaps etter to give the benefit of the doubt to such as ppose this law on what they call a principle; and even if the present law is not as perfect as it might e, to show a disposition to obey it in letter and spirit ntil we can obtain a better one. The quacks are vatching the solution of the problem with interest, nd their fraternity is safe from prosecution so long s legally qualified practitioners remain unregistered, nd by such means openly defy the law.

THE CLAIMS OF COMPARATIVE MEDICINE.

To young men, ambitious of earning their living in scientific pursuits, the facts given elsewhere concerning the condition of comparative medicine should be read with attention. We are told by Prof. Bates that here is one branch of science which offers a rich field for study, and, furthermore, that it is sure to bring substantial pecuniary rewards in a short time. There is, he says, a deplorable lack both of knowledge and skill in most of those who now practise among animals, and the opportunities for helping the removal of such deficiencies are very great. There are now not enough educated veterinary surgeons to furnish the cities of this country with one apiece. There is a constant demand upon the veterinary colleges of this city for skilful practitioners, and those who have been sent out thus far have at once stepped into very lucrative practices.

Veterinary science is one which has been growing rapidly within the past few years. There are two colleges, both in this city, which have done excellent work in educating young men in comparative medicine. They have already secured for themselves a good reputation, and appear to have ample facilities for maintaining it. There are also three veterinary journals, all published in this city, which give evidence that there is much scientific ability as well as professional enthusiasm among those following veterinary practice. It seems to be the aim, and it is a laudable one, of the teachers of this branch of medicine, to make the education of their pupils broad and comprehensive. It is desired to have the graduate not alone a horse-doctor or a cow-doctor, but a man qualified to give medical advice upon the diseases of all domestic animals; to make him, in fact, a doctor of comparative medicine. Such an ambition is to be commended, not only because it will enlarge the scientific knowledge, and elevate the status of the veterinary practitioner, but because it answers a practical need. Of the two billions of dollars which the domestic animals of this country represent, only three-fourths is in horses. The amount of money annually lost by a single disease affecting hogs, is estimated at $20,000,000. Pleuro-pneumonia also causes great losses among cattle, and it is asserted that if the disease should get among the herds of the west, the price of beef in the east would go up to five or even twenty times its present amount.

Obviously it is worth while, therefore, both to the state and to large stock-owners, that there should be men acquainted with these diseases and competent to advise regarding them.

It is not without reason that there has been little reputation in the past associates with the title of "horse doctor." If, however, those who assume this title hereafter show themselves educated, intelligent, and useful practitioners, the reproach will soon disappear. We commend the subject to the attention of the large numbers of young men who are now proposing to enter an overcrowded profession where success is slow and the final compensation not always great.

The results to the human race from a better knowledge of the diseases, such as tuberculosis, which affect domestic animals, are matters on which we need not dwell. It would be in the interests, however, of the more purely scientific branches of medicine, physiology, and pathology, for example, that there should be a more active study of comparative medicine.

THE STATE BOARD OF HEALTH.

The necessity for the creation of a state board of health for New York has been urged so strongly in these columns that we notice with no small satisfaction the promising outlook of the usefulness of the organization. At its recent meeting the real beginning for sanitary reform was made by ordering reports to be prepared for public circulation on certain important sanitary subjects, among which were the pollution of wells and general house-sewage, drainage of towns and villages, danger of kerosene, school hygiene, the prevention of small-pox and diphtheria. Although with full power to make such regulations for abating such nuisances, and for enforcing such sanitary regulations as may seem necessary in the different towns and villages throughout the state, the board wisely prefers as much as possible to act in the advisory capacity. In this respect it is taking the good example of the National Health Board, of which latter body it is the legitimate offspring. The history of true sanitary reform brings out the patent fact that at the bottom of it all is the education of the people and the creation of an intelligent public sentiment in favor of enforcing sanitary laws. Once convince the people that certain things are necessary to their safety—point out the dangers to which they may be subjected by a neglect to comply with certain well-established hygienic laws, and the proper foundations are laid for the enforcement of any regulation which may be deemed necessary. It is this course which must stimulate wise legislation in health matters and which must tend to the creation of laws which, while aiming to protect the community, do not arouse the antagonism of the individual.

It is quite important, in more ways than one, that the state board should vindicate the right of its creation by a liberal and consistent course. Not only is there an immense amount of work to be done in its own particular sphere, but upon it devolves a responsibility of proving the practical working of a law which may be taken as a model for any state in the Union. In no other state is a wider field for intelligent direction on sanitary matters. Not only is New York the most densely populated state in the Union, but it is, by the nature of its surroundings, its extensive and varied trade, its large cities, its aggregation of towns, its water-supplies and the like, peculiarly exposed to unsanitary influences. It is perhaps safe to say that the board fully appreciates this fact and is prepared to act accordingly.

So much, then, for the general purposes of the board, as foreshadowed in the determination to educate the people on sanitary matters. The selection of subjects has been wise. In many of our large towns the privy-vault and water-supply are necessarily but a few feet from each other in a narrow lot. In connection with sewage the drainage of towns and villages can be very properly treated. Concerning offensive trades no better illustration than that afforded at our own Hunter's Point can be selected. The proper means to be adopted to abate this and similar nuisances will doubtless engage the attention of the board. The remedying of the nuisance comes within the pale of its jurisdiction. The prevention of accidents from kerosene is hardly possible, in view of the stupid recklessness of the average servant, but it is clearly within the province of the board to do all it can not only to prevent the sale of impure oil, but to guard against accidents in such as are determined to use it. Diphtheria, ventilation, school hygiene and small-pox are also themes which can be treated in a way to do an immense amount of good and save numerous valuable lives. While awaiting the appearance of the tracts we bespeak for the coming efforts of the board the endorsement of the profession and the appreciation of the public.

THE MALARIAL MANIA.

A correspondent calls attention to the prevalence of what he terms malarial mania among medical men. In many respects we agree with him that it is getting to be too much the fashion to refer everything to malarial infection. There is no doubt that there is a great deal of malarial poisoning to be found throughout the country, but that the numbers affected are greatly overestimated does not admit of a doubt. The frequency with which the diagnosis of malarial element, in almost all diseases, is made by some practitioners, is being noticed by the public, and is not unfrequently an object of ridicule. The knowing patient in a malarious district does not really need to seek the advice of his physician, but can take his quinine by wholesale, and buy it in quantity as he would an article of diet. It would seem that practice of medicine is by many being narrowed down to one diagnosis and one system of therapeutics.

THE AMERICAN ACADEMY OF MEDICINE.

The fifth annual meeting of the American Academy of Medicine was recently held in Newport, R. I. It is gratifying to learn that the organization is in a prosperous condition, and that its aims are being fostered by a goodly share of the representative men in the profession. Established for the purpose of furthering the interests of a higher medical culture, it remains true to itself in keeping the idea constantly before the profession and the public. Dr. Lente, in his annual address, tells us the old story of lack of preliminary requirements on the part of students of medicine, of colleges that admit any and every one able to pay the fees, and of the lamentable deficiencies of medical graduates of to-day compared with those of one hundred years ago. But the old story needs to be told again and again, until the majority of the profession shall believe it to be true, and shall take the necessary steps for reform. The American Academy of Medicine is doing a good work in this direction. It has shown its determination to keep its own standard of qualifications intact, to insist that no one shall be a member unless he shall have enjoyed the advantage of a university training, aside from that in medicine, and consequently it can afford to insist upon equal qualifications in others. Its province as an organization is to show the advantages of higher medical education, and to encourage the rising generation of physicians to fit themselves thoroughly for the practice of their calling—to claim for such a position equal to that of the educated lawyer or clergyman. Such reforms must of necessity be made slowly, but the Academy is taking the right course to accomplish them. It is, after all, the general practitioner and the educated public which must work out the problem, and be educated to the point of demanding a higher grade of matriculants for our medical colleges, and higher qualifications for graduation. The colleges will never take hold of this question, and give it the necessary practical turn, until compelled to do so by a properly educated public opinion. The Academy, as before said, is doing a good work in this direction, and it is still encouraged to go on. The best indications of its successful working are its steadily increasing membership and the growing interest felt in the purposes of its annual meetings.

THE INDEX CATALOGUE OF THE LIBRARY OF THE SURGEON-GENERAL'S OFFICE.

The appearance of the first volume of the index catalogue of the National Library is an event in the history of medical literature in this country which will be hailed with satisfaction by the medical scholars throughout the world. Not only does it open for practical use the vast stores of the library at Washington, but, judging from the present volume, it is calculated to give as complete a line of reference to authors and subjects as can be collected anywhere. As an indication of what the succeeding volumes may contain, we mention that the one before us represents 9,090 author-titles, 8,031 volumes, 6,398 pamphlets, 9,000 subject-titles of separate books and pamphlets, and 34,604 titles of articles in periodicals. The arrangement of subjects is as perfect as can be made to allow of easy and intelligible reference, and too much praise cannot be given for the care and discrimination which has been exercised by Surgeon John S. Billings in bringing about this result. Some time since, with a view of obtaining the opinion of experts throughout the country, Dr. Billings published specimen fasciculi, embodying different methods of indexing, and asked for suggestions tending to improve such methods.

The present plan is the result of the embodiment of the views of the majority, and is, as might have been expected, the most perfect that could have been obtained. The typographical arrangement is excellent, and the variety of type helps to subdivide the subjects for easy and rapid reference. The volume, notwithstanding its bulk—nearly 900 pages—comprises only indices from A—Berlinski. It will be at once assumed that it is impossible to give more than a general idea of the character of the work and of its arrangement, as any attempt to do more would involve something like a detailed review of a dictionary.

It is well known that the authorization by Congress for the publication of this volume was the result of much entreaty on the part of the profession through its press and its medical organizations. That the publication has become an accomplished fact is as creditable to the government as it is beneficial to the profession. If there have been any doubts as to the real utility of the project, the present volume must effectually dispel them, and prove to all directly or indirectly interested that for no more worthy object could Congress have made the appropriation.

Reports of Societies.

THE AMERICAN PHARMACEUTICAL ASSOCIATION.

Twenty-eighth Annual Meeting.

Held in Saratoga, N. Y., September 14th, 15th, 16th, and 17th, 1880.

Tuesday, September 14th—First Day.

The Association met in the concert-room of Congress Hall, and was called to order at 4 p.m. by the President, George W. Sloan, of Indianapolis, Ind.

Chas. F. Fish, of Saratoga Springs, Local Secretary and Chairman of the Local Committee, was then introduced. He delivered the address of welcome, in which he gave a brief historic sketch of Saratoga and its surroundings, and directed special attention to the fact that it was Dr. Stearns, of that county, who in 1809 first brought to the notice of the medical profession the therapeutical use of *ergot.*

President Sloan, in behalf of the Association, returned to Mr. Fish sincere thanks for the cordial welcome.

The President then appointed the following as Committee on Credentials: F. T. Whiting, of Great Barrington, Mass.; E. B. Gordon, of Cincinnati, O.; and G. J. Luhn, of Charleston, S. C.

THE PRESIDENT'S ANNUAL ADDRESS.

The President then delivered the annual address, in which he referred to important changes in the rules of the Association, and the general progress made in pharmaceutical science, and then discussed at some length the topic suggested by a paper read by James G. Steele, on "The Medicinal Plants of California," read at the last meeting of the Association. He considered the effect produced on native medicinal plants by the destruction of our forests, and asked: Can they be successfully and profitably cultivated, and will the cultivated possess the therapeutic virtues of the natural plants? At present these questions cannot be satisfactorily answered, but they are of sufficient importance to demand the earnest attention of pharmacists.

E. Scheffer, of Louisville, Ky.; John Ingalls, of Macon, Ga.; and A. Robbins, of Philadelphia, Pa., were appointed as a committee to whom was referred the President's address.

On motion by H. J. Menninger, the members of the medical and the pharmaceutical professions, residents of Saratoga, were invited to the privileges of the floor.

On motion, the same courtesy was also extended to the Committee on Revision of the National Pharmacopœia, then in session in Saratoga.

The Executive Committee then read the names of 141 applicants for membership in the Association [they were elected at the next session].

The Secretary then called the roll of members, when eighty-six were found to be present.

The Committee on Credentials then presented their report through F. T. Whiting, Chairman, which was accepted and the delegates admitted.

The following gentlemen were then selected as members of the

COMMITTEE ON NOMINATIONS,

one representative being named by each delegation:

New York Coll. of Pharm., H. J. Menninger; National Coll. of Pharm., Chas. Becker; Chicago Coll. of Pharm., Thomas Whitfield; Mass. Coll. of Pharm., B. F. Stacy; St. Louis Coll. of Pharm., O. A. Wall; Cincinnati Coll. of Pharm., W. J. M. Gordon; Philadelphia Coll. of Pharm., A. Robbins; Pittsburgh Coll. of Pharm., F. W. Walker; Montreal Coll. of Pharm., H. S. Evans; Ontario Coll. of Pharm., W. Saunders; Louisville Coll. of Pharm., E. Scheffer; Maryland Coll. of Pharm., J. Roberts; Alumni Assoc. of Mass. Coll. of Pharm., Wm. W. Bartlett; Alumni Assoc. of New York Coll. of Pharm., S. H. Ambler; Alumni Assoc. of St. Louis College of Pharm., O. A. Wall; Alumni Assoc. of Louisville Coll. of Pharm., O. Beckman; Alumni Assoc. of Philadelphia Coll. of Pharm., E. M. Hatton; Alumni Assoc. of Cincinnati Coll. of Pharm., H. Serodina; Wisconsin Pharm. Assoc., J. A. Dadd; New Hampshire Pharm. Assoc., C. A. Tufts; North Carolina Pharm. Assoc., W. Simpson; Connecticut Pharm. Assoc., A. F. Wood; Kings County Pharm. Assoc., W. P. De Forest; South Carolina Pharm. Assoc., G. J. Luhn; Vermont Pharm. Assoc., A. W. Higgins; Iowa State Pharm. Assoc., Geo. H. Schaefer; New Jersey Pharm. Assoc., G. H. White; Newark Pharm. Assoc., Chas. Holzhauer; Pennsylvania Pharm. Assoc., J. H. Stein; New York Pharm. Assoc., L. E. Nicot; Kansas Pharm. Assoc., G. H. Ferdinand; Ohio Pharm. Assoc., T. J. Casper; Georgia Pharm. Assoc., John Ingalls; Kentucky Pharm. Assoc., J. F. McKinnie; Pharm. Assoc. of the Province of Quebec, R. McLeod; Literary and Scientific Society of the German Apothecaries of the City of New York, P. F. Lehlbach.

The President appointed from the Association at large, in addition to the above, J. G. Thibodeaux, of La.; W. B. Blanding, R. I.; Wm. J. Morley, Texas; E. Martin, Ind.; E. Bocking, W. Va.

The President also announced the following as the Committee on Exhibitions: C. H. Dalrymple, N. J.; C. Huston, O.; Wm. Blaikie, N. Y.; P. C. Candidus, Ala.; and G. H. Schaefer, Iowa.

The Business Committee then called up the report of the Committee on By-laws relating to Business Council, and it was read by J. P. Remington, of Philadelphia.

On motion, the report was made the special order for Wednesday morning, immediately after the completion of the regular order of business.

WEDNESDAY, SEPT. 15TH.—SECOND DAY.

The Association was called to order at 9.45 A.M. by the President.

The minutes of the previous session were read by the permanent Secretary, John M. Maisch, of Philadelphia, and adopted.

REPORT OF THE COMMITTEE ON NOMINATIONS.

The Committee on Nominations, Charles A. Tufts, Chairman, presented the following nominations for officers and committees for the ensuing year:

For *President*, James Thornton Shinn, of Philadelphia, Pa.; for *1st Vice-President*, Geo. H. Schaefe of Ft. Madison, Iowa; for *2d Vice-President*, Wm. F Thompson, of Washington, D. C.; for *3d Vice President*, Wm. Simpson, of Raleigh, N. C.; fo *Treasurer*, Charles A. Tufts, of Dover, N. H.; fo *Permanent Secretary*, John M. Maisch, of Philadelphia, Pa.; for *Reporter on Progress of Pharmacy* C. Lewis Diehl, of Louisville, Ky.

Executive Committee.—Geo. W. Kennedy (Chairman), Pottsville, Pa.; Adolph W. Miller, Philadelphia Pa.; Charles Huston, Columbus, O.; Thomas Doliber, Boston, Mass.; John M. Maisch, ex-officio.

Committee on Drug Market.—Louis Lehn (Chairman), of New York; James F. Steele, of San Francisco; Isaac L. Lyons, of New Orleans; Thoma Whitfield, of Chicago; John P. Muth, of Baltimore.

Committee on Papers and Queries.—J. U. Lloy (Chairman), Cincinnati, O.; Starr H. Ambler, of Ne York; Wm. W. Bartlett, of Boston.

Business Committee.—H. J. Menninger (Chairman) of Brooklyn, N. Y.; Charles L. Eberle, of Philadelphia, Pa.; Ed. H. Heinitsch, of Columbia, S. C.

Committee on Prize Essays.—C. Lewis Diehl (Chairman), of Louisville, Ky.; John F. Judge, of Cincinnati, O.; E. Scheffer, of Louisville, Ky.

Committee on Legislation.—John M. Maisch (Chairman), of Philadelphia, Pa.; Jesse W. Rankin, o Atlanta, Ga.; Samuel A. D. Sheppard, of Boston Mass.

On motion by P. W. Bedford, of New York, th report was accepted and the Association proceede to ballot for President; C. S. Eastman, of Concord N. H., and Jos. Roberts, of Baltimore, Md., acting as Tellers. James Thornton Shinn was unanimousl elected. The Secretary was then instucted by th Association to cast an affirmative ballot for the remaining gentlemen put in nomination, and they wer declared elected.

The Chairman of the Executive Committee calle the attention of the Association to the Centennia Fund, and moved the appointment of a committe to solicit subscriptions. C. L. Eberle, of Philadelphia, Pa.; C. Lewis Diehl, of Louisville, Ky., and A. E. Ebert, of Chicago, were appointed, and th Committee subsequently reported that $120 had been raised.

The Chairman of the Executive Committee, GEO. W. KENNEDY, then read the annual report of th Committee, which was accepted.

The report showed that the total membership a the close of the last annual meeting was 1,208. Since that date there had been a total loss of 58 members, leaving 1,150 in good standing. Of the 58 member lost, 12 active and 3 honorary members have died. To those three other names were added, making the total number of deaths 18 during the year.

Obituary sketches were read of A. E. Dunk, Erie, Pa.; Michael H. Gleason, Boston; Samuel K. Gilman, Boston; Jas. W. Rideout, Brooklyn; John J. Cross, Louisville; Geo. J. McKay, Cal.; J. W. Haddox, Nashville; Jas. A. Gleeson, Boston; Chas. F. Mohr, Bonn; Prof. Chevalier, Paris; and —— Wiggers. The names added to the list were Wm. Neergaard, of New York; W. S. Merrill, of Cincinnati; and Thomas Lewis, of Brooklyn.

The report of the Permanent Secretary was then read and accepted.

The Treasurer, CHARLES A. TUFTS, of Dover, N. H., then read his report, which showed that there was a balance in the treasury, not including the receipts of the present session, of $1,461.61.

The report was accepted, and referred to an auditing committee, consisting of W. J. M. Gordon, of Cincinnati; C. H. Dalrymple, of Morristown, N. J.; and Geo. W. Sloan, of Indianapolis.

C. LEWIS DIEHL, of Louisville, then read his report on the progress of pharmacy, which was accepted.

The report of the Committee on Drug Market, L. Lehn, New York, Chairman, was read by J. P. REMINGTON, of Philadelphia. It consisted of brief references to drugs and new remedies, chiefly as regards their price and general use.

The Committee on Prize Essays reported that they had not awarded any prize because none of the papers submitted were worthy of such commendation.

The Committee on Legislation, John M. Maisch, Chairman, asked leave to submit the report in writing to the Committee on Publication, which was granted.

P. W. BEDFORD, Chairman of the Committee on Membership, then read his report, which was accepted.

The report of the Committee on Publication of the Report on the Revision of the U. S. Pharmacopœia was then read, and showed that contributions were received from more than one hundred sources, amounting to $812.50. The expenditures were $733.71, leaving a balance of $78.79, which was transferred, by consent, to the Centennial fund.

On motion by H. J. Menninger, the financial portion of the report was referred to the Auditing Committee appointed to audit the Treasurer's report.

The Chairman of the Executive Committee then read the names of sixteen additional applicants for membership, making a total of 157.

The Business Committee then called up the Report of the Committee on By-laws (relative to business council), and it was read by J. P. Remington, of Philadelphia, Chairman of the Committee. The essential feature of the report was that it provided for creating a council that will take the place of the Executive and Business Committees, and thus relieve the general Association of its cumbersome detail work. After considerable conversational and explanatory discussion, the report of the committee was adopted, three-fourths of those present voting in the affirmative. The Council will consist of seventeen members, nine of whom shall be elected by ballot by the Association in the following manner: *three* to serve *one* year, *three* to serve *two* years, and *three* to serve *three* years, and at each subsequent annual meeting three members shall be elected to take the place of those whose terms of office shall then expire, and to serve for a term of three years.

The President, the three Vice-Presidents, the Secretary, the Treasurer, the Local Secretary, and the Reporter on the Progress of Pharmacy shall be *ex-officio* members of the Council.

The members of the Council to be elected at each annual meeting shall be placed in nomination by the Committee on Nomination. The officers shall consist of a Chairman, a Vice-Chairman, and a Secretary, to be elected by ballot annually by the Council. All vacancies in the Council shall be filled by the Association at the annual meeting next following their occurrence. The Council shall be charged with the transaction of unfinished business of the Association, and shall arrange the business of the sessions during the annual meetings, etc.

There shall be elected annually, by ballot by the Council, three standing committees: one on membership, one on publication, and one on finances, to whom shall be referred the business of those departments, and who shall report annually to the Council, or oftener if the Council shall so direct.

The Council shall have charge of the roll and the publication of the proceedings.

The names of the applicants for membership shall be read in a general session of the Association, and new members shall be elected by ballot by the Council. No name shall be voted upon unless presented by the Council, and the Council shall decide upon any objection presented with reference to candidates for membership. All business of the Association not of a scientific character shall be in charge of the Council, the minutes of which shall be read in full at each annual meeting, and their acts shall be subject to revision by the Association.

On motion by Dr. E. R. Squibb, of Brooklyn, the Committee on Nomination was instructed to present the names of nine members for the Council, to be balloted for at the last session of the present annual meeting.

The Association then adjourned, and accompanied the Committee in making an examination of the specimens on exhibition.

THURSDAY, SEPT. 16TH.—THIRD DAY.—MORNING SESSION.

The Association was called to order at 10 A.M. by the President.

The Secretary read a telegram from the California College of Pharmacy, bringing greetings to the American Pharmaceutical Association.

The Business Committee asked for the appointment of a committee which should report on the time and place for holding the next annual meeting.

Invitations were announced from Cincinnati, Chicago, Kansas City, Asbury Park, Washington, D. C., Milwaukee, and Peoria.

The President appointed as the Committee, G. F. H. Markoe, E. Lilly, and G. J. Luhn.

A NEW PLAN FOR THE FORMATION OF THE COMMITTEE ON NOMINATIONS.

DR. E. R. SQUIBB, of Brooklyn, introduced a resolution providing for a change in the By-Laws concerning the formation of the Committee on Nominations. It was substantially as follows: Immediately after the reading of the minutes of the preceding session, in the second session of each annual meeting, it shall be the duty of the presiding officer to call upon the delegation from States, Districts, Territories, and Provinces to select one delegate from each State, District, Territory, or Province, and report the name of such delegate to the Association as the chosen member of the Nominating Committee. The names so reported, together with the last President of the Association, or in his absence one of the last Vice-Presidents, shall constitute the Nominating Committee.

Joseph Roberts, of Baltimore, offered, as an amendment, that immediately after the reading of the minutes of the preceding session, in the second session of each annual meeting, it shall be the duty of the presiding officer to call upon the Association to nominate persons to be voted for for the positions of President, First, Second, and Third Vice-Presidents for the ensuing year, and that the Association shall at once proceed to elect these officers by ballot. All the other officers of the Association shall be nominated by the Council.

On motion by J. P. Remington, of Philadelphia, the consideration of the resolution and its amendment was made a special order for the afternoon session.

Oscar Oldberg, of Washington, D. C., read an exhaustive paper on *Pharmacopœial Nomenclature*, which was discussed by J. P. Remington, E. R. Squibb, and John M. Maisch.

On motion by P. W. Bedford a vote of thanks was given to Prof. Oldberg for his admirable paper.

The Chairman, E. Scheffer, of the Committee on the President's address, reported in favor of heartily indorsing the action of the Committee on Legislation, from the Western Druggists' Association, in its efforts to secure either a repeal or a modification of the law concerning the stamp tax on medicine, perfumery, etc.

On motion by J. F. Moore, of Baltimore, this portion of the report was subsequently amended by inserting the words "excepting proprietary medicines," and then adopted by the Association. Resolutions were also adopted providing for the carrying into effect of the action of the Association.

Charles F. Fish, of Saratoga, then read a paper on

THE MINERAL SPRINGS OF SARATOGA.

The author first gave a brief historical sketch of the village of Saratoga and its surroundings, and then proceeded to speak of the theories concerning the sources of its mineral waters. All the rocks of this county belong to the lowest systems of geological formations, and are both metamorphic and sedimentary in character (the geological formations were represented upon a chart). The theories concerning the origin of the mineral waters are two in number.

First, that they are produced by the process of displacement, or percolation of the surface water through the rocks, and carrying with the various constituents of which the rocks are composed, and reappear at the "fault" in the geological strata caused by an upheaval of remote origin.

Second, that the water derives its mineral properties at the "fault," and is essentially unimpregnated until that point is reached, and that its mineral constituents are obtained from the heated interior by the process of sublimation and subsequent absorption, while the gases are also derived from the same source in a free state.

The author then described the method of securing the mineral springs of this locality. The depth at which the rock is situated below the surface varies from fifteen to fifty-seven feet. The springs secured by drilling into the rock vary in depth from fifty to three hundred feet in depth, and the temperature of the water obtained is practically isothermic: the maximum being 52° and the minimum 40° F., and the flow and temperature being uniform throughout the year. The Geyser, Vichy, Champion, Kissingen, and the so-called Magnetic (which is devoid of magnetic properties) springs were obtained by drilling.

The author then gave a classification of mineral waters, and subsequently referred to the therapeutical application of this natural remedial agent.

The Committee on the *time* and *the place* for holding the next annual meeting then reported in favor of Washington, D. C., and the meeting to be held in September, 1881, beginning on the *second* Tuesday.

Discussion was postponed until the afternoon session, when the report was amended by designating Kansas City, Mo., as the place, and changing the time to the *third* Tuesday in August.

In the first morning session on Friday, the time of holding the annual meeting was changed to the *fourth* Tuesday in August.

C. Lewis Diehl, of Louisville, Ky., then read a paper on

FLUID EXTRACTS.

Dr. E. R. Squibb, of Brooklyn, asked Prof. Diehl whether or not he noticed any considerable proportion, with a weak percolate, that remained insoluble in the fluid extract; and also whether he noticed that the residue of the evaporated portion was of the same character as the contents of the reserved portion. He regarded these as prime points in considering the value of the process proposed for making fluid extracts. The value of the claim for the process of repercolation depends particularly upon the total avoidance of heat in the making of fluid extracts, and, if it be of any force at all, the above questions were pertinent to it.

Another point was with reference to the adoption of volume for weight, and not weight for weight, as decided upon by the Committee on the Revision of the Pharmacopœia. He asked whether any experiments had been made to determine whether or not the menstruum used might not be so modified as to bring the matter within practical reach; that is to say, cannot the menstruum be so modified as to represent weight for weight? The point made was that a menstruum that did not dissolve the constituents of the drugs afterward, although it might extract them, would not produce a liquid that contained the constituents of the original substance.

Prof. Diehl replied that in his first paper on this subject he had stated that when the original menstruum was restored in the proportion in which it was before evaporation, the extracts were almost always dissolved again. That point he has settled with regard to the fluid extracts upon which he had made experiments previously, and, in making the experiments reported in the present paper, he had found that the same thing held true with reference to nearly all of them. On general principles he was opposed to any such method, because it will lead us to adopt menstruum which will not be proper for the best extraction of a drug, holding everything extracted in solution. He thought, however, that if a reasonably fair set of formulæ could be obtained for the pharmacopœia, we should be reasonably satisfied.

Prof. John M. Maisch, of Philadelphia, remarked that, while be believed with Dr. Squibb that it would be well to harmonize volume and weight, he would go even farther, cite instances in which that cannot be done, and give it as his opinion that fluid extracts should be made weight for weight. He thought it was a great mistake to use only weights in the Pharmacopœia, except with reference to one class of preparations.

FERRIC HYDRATE.

The next paper, an answer to query 20, was read by G. F. H. Markoe, of Boston.

"What are the advantages and objections to preparing ferric hydrate by the use of concentrated solutions of ammonia and ferric sulphate, as compared with the use of diluted solutions, with the special object of employing the ferric hydrate in making the cale salts of iron."

He advocates the use of the dense form of ferric hydrate for use in making other iron preparations. This dense hydrate is, of course, obtained by using more concentrated solutions. It may be prepared either with ordinary or with stronger water of ammonia.

Hydrated ferric oxide, as an antidote for arsenic, should be prepared from *dilute* solutions, in order to insure more rapid solubility in acids.

Dr. Squibb thought that if Prof. Markoe had extended his observations to the precipitate afterward, and said how much sulphate of ammonia was left in the iron, he would have covered the ground more closely. He thought Prof. Markoe would have found, by so doing, that considerable sulphate of ammonia was left in the iron precipitated, and that it was not washable out, in the ordinary sense, and also that it was very effectual in rendering the hydrate soluble in citric acid, and other things added afterward.

Prof. Markoe remarked that he was aware of the fact mentioned by Dr. Squibb, in a chemical point of view, and that he recommended the preparation exhibited merely for specific purposes.

RHAMNUS PURSHIANA.

The next paper was an answer to query 12, and was read by Geo. W. Kennedy, of Pottsville, Pa.

"Rhamnus purshiana has attracted considerable attention as a purgative remedy. What forms of galenical preparations of it are desirable, and how should they be prepared?"

The writer recommended a fluid extract and an elixir as the only preparations, to his knowledge, at this time prescribed and used. He recommended an elixir made from the weaker pharmaceutical preparations, because it is more palatable.

ASPIDIUM MARGINALE.

Geo. W. Kennedy also read an answer to query 16.

"Aspidium marginale has been found by Mr. C. H. Cressler to be very similar in its medicinal value to the European Aspidium *filix mas*. Can the rhizome of the American plant be obtained in quantities? If so, should the latter not be recognized by our Pharmacopœia in place of *filix mas?*"

The answer was, that, since its therapeutic properties have been found efficient, there should be no objection to its introduction into the Pharmacopœia, and the two substances used indiscriminately in the preparation of the oleoresin.

The next paper was an answer by S. L. Coffin, of Chicago, to query 17, and was read by Dr. H. J. Menninger.

"Aromatic Spirits of Ammonia has been Proposed as a Menstruum for Exhausting Lupulin. Has this any Advantage over Alcohol?"

He stated that he finds them equally good for this purpose. He has also learned from physicians that the tincture prepared with the aromatic spirit of ammonia presents no therapeutic advantages.

The Committee on the Centennial Fund then reported that the amount of money in their hands was $577.81, thus insuring to the Association the $500 offered by residents of Philadelphia and vicinity.

Third Day.—Afternoon Session.

The Association was called to order at 3.45 p.m. by the First Vice-President, G. H. Schaefer, of Fort Madison, Iowa.

The special order being Dr. Squibb's resolution, providing for a new plan of forming the Nominating Committee.

Mr. Jos. Roberts, of Baltimore, offered his amendment, which gave rise to discussion that was participated in by J. P. Remington, A. E. Ebert, L. E. Nicot, G. F. H. Markoe, C. Eberle, G. M. Baker, Maine, and J. F. Moore.

Mr. Nicot, of Brooklyn, moved to postpone the question indefinitely. Lost: ayes, 44; nayes, 53. The discussion was continued, and W. P. De Forest, of Brooklyn, moved to lay the subject on the table. Ayes, 52; nayes, 52. The Vice-President cast his vote in the negative, and after further discussion a vote was reached upon the substitute, which was adopted. Ayes, 62; nayes, 21. A vote by ballot was then taken on the original resolution, as amended, and it failed to secure the requisite three-fourths to adopt it. Ayes, 69; nays, 44. A ballot was then taken for the names of sixteen candidates for membership, and all were unanimously elected.

The Auditing Committee reported that they found the Treasurer's account correct, and also the financial portion of the report of the Committee on the Revision of the Pharmacopœia. The report was adopted, and a special vote of thanks extended to the Treasurer for his faithful and efficient labors.

J. U. Lloyd, of Cincinnati, O., then read a paper in answer to Query 21:

"The Resin of Leptandra Virginica (the Leptandrin of Commerce) varies much in Appearance and Sensible Properties. To what Cause are these Varying Results to be attributed? What is the Best Process for the Preparation of the Resin, and what is the Average Yield of the Root?"

The commercial "leptandrin," as made by different manufacturers, varies considerably in appearance. This is owing to two causes, viz.: first, to a difference in fineness of powder; and second, to a difference in composition.

If an alcoholic tincture of the root of *Leptandra Virginica* is evaporated to a thick syrup, and the latter is poured into cold water, a black, tarry substance separates. On being washed with water, it becomes tasteless, and may be dried and powdered. At present, manufacturers probably prepare "leptandrin" by another process, and not by precipitation. Prof. John King made his original preparation from the root in this manner. But his therapeutical observations are based on the results obtained from a dried mixture of the aqueous and alcoholic extract.

"Leptandria" was discovered by Merrel, in 1850. This substance, however, has been found to be devoid of medicinal properties. The active principle has so far not been isolated; yet it is well known that the root, as well as the active kinds of "leptandrin," possess laxative properties.

Mr. Lloyd exhibited a large mass of the precipitates above mentioned, the result of working with 1,000 lbs. of the root.

The next paper was read by Frederick B. Power, of Philadelphia, and entitled: "Constituents of the Rhizoma or Asarum Canadense."

The Executive Committee then announced the names of *eight* candidates for membership. They were elected at a subsequent session, making in all 165 new members.

Friday, Sept. 17th.—Fourth Day.—Morning Session.

The Association was called to order at 9.30 a.m. by the President, and the minutes of the previous session were read and approved.

A. G. Vogeler then read a paper on a "Formula for Syrup of Liquorice Root."

This was followed by a paper by Louis Dohme, of Baltimore: "Would the Substitution of Citrate of Sodium for Citrate of Ammonium in the Officinal Pyro-phosphate of Iron, make the latter less liable to become insoluble in keeping?"

A paper was also read upon the same subject by C. Caspari, Jr., Baltimore, Md.

A paper on "Elixirs," accompanied by samples, was then read by R. W. Gardner, of New York, in which, after pointing out the absolute necessity of establishing standard formulæ for the principal elixirs, he proposed that the Association appoint a Standing Committee on Elixirs, and that the members be requested to send to that Committee samples of all elixirs considered proper; each bottle to bear a label giving the working formula, date of preparation, and name of contributor; that the Committee prepare elixirs from such published formulæ as may be thought proper; that these various specimens be kept, and their condition reported upon, or exhibited each year, for say three years, at the end of which period such preparations as have stood the test of time, are the most palatable, etc., be given the sanction of the Association, credit being given to the originator.

The author submitted several formulæ.

A. G. Vogeler, of Chicago, then read a paper in answer to Query 10:

"Fruit Syrups; an Essay on them, with Special Reference to their Probable Introduction into the next Pharmacopœia."

These may be prepared either by combining the juice, expressed from the fruit, with sugar, or the uninjured berries are mixed with the sugar, when the latter will extract the juice, leaving the berries shrivelled and tasteless. Among the fruit syrups discussed by Mr. Vogeler, *Syrup of Raspberries* is the most important. He quotes the following different methods of preparation:

1. Contuse the berries, put them into a suitable vessel or vat, add two per cent. of sugar, and allow them to ferment at a temperature of 70–80° F. from three to four days, until the pectin has separated, and no more signs of fermentation are noticeable. Express, let the juice settle for a few days in a cool place, decant and filter. Preserve the juice by Appert's process (introducing the juice into stout bottles, not quite filling them, corking, setting them into a vessel full of cold water, with straw packed between them, so that the water reaches up to the shoulder, and slowly heating the water to boiling; then securing the cork with wax), or convert it into a syrup by dissolving nine parts of sugar in five of the juice, and heating to boiling.

2. A better way is to add at once to the freshly bruised fruit five to six per cent. of alcohol; then proceed as in No. 1.

3. Crush the berries in a glass vessel with a wooden pestle, add five to ten per cent. of cane or grape-sugar, and allow to stand, stirring occasionally. When fermentation is completed the juice becomes clear. Filter and bottle.

4. Put 4 lbs. of the berries into a china bowl with 1 qt. of water containing 2½ oz. of citric acid in solution. Let remain twenty-four hours. Strain, taking care not to bruise the fruit. To 1 pint of the clear liquid add 1¼ lbs. of sugar, and stir until it is dissolved.

5. Proceed as in No. 1. When the fermentation is nearly over, express the juice, and add to each pound of it f. ℥ j. of deodorized alcohol. Set it aside for one night, filter and bottle, or convert into syrup.

6. Macerate the berries interspersed with layers of sugar, 1¾ lbs. to 1 lb. of berries, for twenty-four hours, in a cool cellar, and drain off the juice. Preserve by Appert's process.

7. Add to the foregoing product some alcohol or a little bisulphite of lime.

8. Pure fruit-juice, ℥ xvi.; dil. acetic acid, f. ℥ j.; water, f. ℥ vii.; granulated sugar, 3 lbs. Dissolve without heat. The acetic acid is considered by the author as objectionable.

The *Nominating Committee* then completed their report, as follows:

For *Local Secretary:* Wm. F. Ford, of Kansas City, Mo.

For *Members of the Council,* to serve *three* years: J. P. Remington, of Philadelphia, Pa.; G. W. Kennedy, of Pottsville, Pa., and H. J. Menninger, of Brooklyn, N. Y. To serve *two* years: Thomas Whitfield, of Chicago; Wm. Saunders, of London, Ont., Canada; and S. A. D. Sheppard, of Boston, Mass. To serve *one* year: W. J. M. Gordon, of Cincinnati, O.; John Ingalls, of Macon, Ga.; and Joseph Roberts, of Baltimore.

The Secretary was instructed to cast an affirmative ballot for Mr. Ford for Local Secretary.

The Association then balloted for members of the Council, and the gentlemen nominated by the committee were unanimously elected.

The *Committee on New Membership* was enlarged, so that it consists of the following members: P. W. Bedford, of New York; E. C. Jones, of Philadelphia; S. A. D. Sheppard, of Boston; R. H. Cowdrey, of Chicago; G. A. Schaefer, of Ft. Madison, Iowa; Jas. G. Steele, of San Franciso, Cal.; Thos. J. Casper, of Springfield, O.; Wm. Moll, of Saginaw City, Mich.; Rudolph H. Hasting, of Denver, Col.; H. J. Rose, of Ontario, Canada; L. M. Connor, of Dallas, Texas, and John Ingalls, of Macon, Ga.

A vote of thanks to the Committee on New Membership for last year was unanimously adopted.

On motion by the Business Committee, a vote of thanks was unanimously tendered to the Local Secretary, Mr. Chas. F. Fish, and to the citizens of Saratoga, for the efficient and courteous management of the details connected with the annual meeting.

The names of three candidates for membership were then read, and the Association took a recess of five minutes.

At the expiration of that time the Association was called to order, and the minutes of the previous session were read and approved.

The three candidates for membership were then balloted for and unanimously elected, making a total of one hundred and sixty-eight new members elected at this annual meeting.

A. B. Huested, of Albany, moved that the thanks of the Association are hereby tendered to the proprietors of the Saratoga mineral springs for their kindness and courtesy during the present annual meeting of the Association.

C. Eberle, of Philadelphia, moved that a vote of thanks be tendered the proprietors of the Congress Hall, which was unanimously carried.

On motion by Wm. Saunders, the thanks of the Association were extended to the retiring officers for their efficient services.

C. H. Dalrymple, Chairman of the Committee, reported that the Committee had carefully examined all the exhibits, and asked permission to prepare their report in writing for the Committee of Publication, within thirty days. Leave was granted.

The list of queries was then read by the Secretary.

On motion by H. J. Menninger, the queries to which no response had been received will be dropped from the list unless notice be given to the Secretary at once, by the gentlemen who accepted them, that they wish to continue them for another year.

The minutes of the present session were then read and approved, and the President then declared the Association adjourned, to meet in Kansas City on the fourth Monday of August, 1881.

The whole number registered at the twenty-eighth annual meeting was one hundred and eighty-seven.

◆

AMERICAN ACADEMY OF MEDICINE.

Fifth Annual Meeting.

THE Academy assembled at Manning Hall, Brown University, Providence, R. I., on Tuesday, September 28th. The first session was a business meeting at 4 P.M. About twenty-five fellows were present. **DR. FREDERICK D. LENTE**, of New York, President of the Academy, occupied the chair.

ELECTION OF NEW MEMBERS.

First came the election of new members, the following gentlemen being made fellows of the Academy: Drs. James Chester Morris, Philadelphia; H. Webster Jones, Samuel J. Jones, and Chas. Gilman Smith, Chicago; P. S. Conner, Cincinnati; Cornelius Rea Agnew, New York; Chas. O'Leary, Providence, R. I.; Robert Amory, Brookline, Mass.; J. W. C. Ely, Providence, R. I.; Theophilus S. Hartley, Ridgeway, Penn.; Lloyd Morton, Pawtucket, R. I.; Albert E. Ham, George W. Porter, and George D. Hersey, Providence, R. I.; Theodore T. Wing, Susquehanna, Penn.; Francis M. Perkins, Philadelphia; Audley Haslett and Joseph Mott Turner, Brooklyn, N. Y.; Lemuel J. Deal, Philadelphia; Nathan Allen, Lowell, Mass.; William Elmer, Jr., Trenton, N. J.; Chas. Carroll Lee, New York; William Elmer, Princeton, N. J.; Lewis D. Harlow, Philadelphia; Theophilus Parvin, Indianopolis, Ind.; Albert H. Smith, Philadelphia.

The reading of the report of the "Council" was next in order, by the Secretary, **DR. RICHARD J. DUNGLISON**, of Philadelphia.

A proposed amendment to the constitution was brought up and discussed, but will lie over until next year's meeting for conclusive action. It related to clauses first and second of Section II., Article III., which designate the requirements for admission to the Academy. As amended, the two clauses will be united into one, and read as follows: "The degree of Bachelor of Arts, *or* Master of Arts, etc.," clause fourth of the same section to be correspondingly amended.

CERTIFICATE OF MEMBERSHIP OF THE ACADEMY.

Drs. P. D. Keyser, R. J. Dunglison, and L. H. Steiner were appointed a special committee to prepare a "certificate of membership" for the Academy, and have the same engraved and printed. A committee of three was also appointed to nominate a list of officers for the coming year.

REGULATING THE PRACTICE OF MEDICINE.

It was moved that the "Council be instructed, during the next year, to collect all the laws in any degree bearing on the regulation of the practice of medicine in all the states of the Union and also in the Dominion of Canada, and to prepare a digest of the same for presentation to the Academy at its next annual meeting." After brief discussion the resolution was adopted.

It was next voted to invite President Robinson, of Brown University, to open the evening session with prayer. The faculty and students of the University were also cordially invited to be present, it being announced from the Chair that it was pre-eminently one of the objects of the Academy to interest and instruct *young* men in the subjects under consideration. The business meeting then adjourned till 10 A.M. the next day.

After prayer by Rev. Dr. Robinson, **DR. FREDERICK D. LENTE** delivered the annual address, which was the special object of the session. After a few introductory words, the subject of the evening was announced to be

THE HIGHER EDUCATION OF MEDICAL MEN,

and its influence on the profession and the public. Dr. Lente admitted that our profession did not occupy so favorable a position with regard to the public as it did in its earlier stages. The same was true of the legal and other professions. If we would reform evils we must thoroughly understand their nature. The standard of medical schools had deteriorated. Those of a hundred years ago required a far higher preliminary standard than those of today. How was it possible for a student to mentally digest all the varied subjects now gone over in the short time allotted to them. Forty years ago students were obliged to work all their time in order to pass examination for their degree in medicine, but there were no special branches taught then.

There were far too many medical schools. In the United States, twenty-one, known as "regular," were established between 1867 and 1876. The natural outgrowth of excess in number of schools was a great rivalry among them respecting their number of students, and their chief aim seemed to be, not so much to make *good* doctors as a large number of doctors. It becomes a question of *duty* v. *interest* with these too numerous medical institutions. In some countries a population of twenty-five hundred, and in this, one of fifteen hundred, was required to support a physician decently, and keep him in a condition to work effectively in his profession. But in the United States there was now a physician to every six hundred inhabitants, whereas, in thirteen other countries, there was only one in twenty-eight hundred. A whole book might be written on the vicious results of overcrowding the ranks of our profession. A great number of doctors had to *struggle* for the bare necessaries of life—work so hard for a *living* that the higher aims of a physician's life were lost. The lamentable instances of gross ignorance and carelessness were too frequent. Despite, however, certain unfavorable conditions, many American physicians stand second to none in the world. In the realms of uterine surgery and anæsthesia, for instance, our position was very high. Our medical literature was beginning to command the attention of the world, though the number of published works was still ridiculously small. It was a significant fact, that the preliminary education of many men, high in our ranks as practitioners, was insufficient to admit of their ever becoming authors. The Medical and Surgical Report of the U. S. Army and Navy, deserved highest praise, as does also the National Medical Library.

How could the number of physicians be limited? was an important question. Why not, like manufactories, "shut down" when supply was in excess of demand, and not produce so many? The doors were too wide open to the study of medicine—much more so here than in other countries.

The study of medicine had come to be regarded as a very simple affair; hence, our ablest young men went into law or theology. Those who were too lazy to work, or too dull to take up with law or the ministry, studied medicine. In England not two per cent. of medical students were graduates of the universities. But a change was already taking place. Progress in science, and interest in sanitary science, and the greater circulation of scientific periodicals among the people, rendered a physician poorly read in scientific subjects no longer safe among his patrons. How to raise the standard of medical education was the vital question. Various attempts had been made by appointing one and another board of examiners, censors, etc. The National Association of Medical Colleges had sought to enforce a *three years'* course; the American Medical Association had made one committee after another, but none of these methods had been sufficient. The same had been true of England. Preliminary examinations had been urged, but what did they amount to? Sir Wm. Gull's idea was to have the examination conducted by men not in the profession. In Germany preliminary examinations were not relied on; they were a measure of *cramming* and not of real acquisition. What means, then, are left? Refer to the constitution of the American Academy of Medicine, Article II., wherein the objects of the Academy are stated to be, 1st, "to bring those who are alumni of classical, scientific, and medical schools into closer relations with each other," and, 2d, "to encourage young men to pursue regular courses of study in classical and scientific institutions before entering upon the study of medicine." Young men should be made to show evidence of good preliminary training before they were allowed to commence professional study; in other words, must have received a degree from some respectable college which required a four years' course after two years of preparatory study.

This may seem utopian, and objections might be raised, some of which might be anticipated. Exceptional cases were quoted where a few rare men, like John Hunter, had risen from no preliminary discipline to the first rank in the profession. But such men, more than any others, themselves missed and lamented their loss of early advantages. Many professors in medical schools had no A.B. True, but the degrees of A.B. and A.M. did bear evidence of a certain number of years of devotion to study and life in literary surroundings. It may be claimed that too much time was wasted in college curriculums. Dr. Lente maintained that the classics had a value in medicine above a mere literary and linguistic discipline. A medium course between the classics and a too purely scientific course would best meet the demand. It had been said that improvements had already been made in longer terms and more thorough preliminary requirements. This did not apply, surely, to the great majority of schools. Too great exclusiveness might be charged. He asked, in reply, Who could not go to college these days? If the average young man so wills, he can accomplish it. Indeed, this profession *should be* more *exclusive* than any other, and a degree in medicine should mean the same the world over, whether under the auspices of anarchy, monarchy, or republic. This *exclusiveness* would help rid us of superfluous members. The *guarantee* of a literary education was what distinguishes the American Academy of Medicine, and its diploma would be of aid at home and abroad. Members of the profession at large might be excluded from our ranks by one clause in our constitution. He urged the importance of clinical teaching, and regretted that it could be enjoyed by so comparatively few. He approved of state boards of examiners for the degree of M.D., and the college which would not educate for such an examination should not be supported. The plan of conjoint boards of examiners was now being agitated. Cease granting charters to any more medical societies without the approval of the State Society.

He claimed that *three* years was not enough to teach all that pertained to practice, and it was simply impossible for the student to gain a thorough knowledge of the special branches in the time allotted to them. The profession had probably sustained no greater disgrace than from the conflicting opinions of pseudo-experts. Any union of medicine and state was not to be thought of. The lectureships and lecturers in our schools of highest standard were well worthy our respect and praise.

The closing session of the Academy occurred Wednesday, September 29th, at 10 A.M. Dr. Lente presided.

Dr. E. H. M. Sell, for the Committee on Nominations, reported the following list of officers for the coming year, all of whom were unanimously elected: *President*—Edward T. Caswell, M.D., of Providence, R. I. *Vice-Presidents*—Henry Orlando Marcy, M.D., of Cambridge, Mass.; Wm. T. Taylor, M.D., of Philadelphia; Howard Pinckney, M.D., of New York; Horace Lathrop, M.D., of Coopertown, N. Y.

Secretary and Treasurer—Richard J. Dunglison, M.D., of Philadelphia. *Assistant Secretary*—Charles McIntyre, Jr., M.D., of Easton, Penn.

Dr. Traill Green offered the following: *Resolved*, "That the thanks of the Academy be presented to the authorities of Brown University for their hospitality, and to the resident members of the Academy for their efficiency in providing for this session."

The above resolution was unanimously adopted, and also another. thanking the President for his able address, and referring the same for publication. Then, there being no motion before the meeting, an informal discussion took place on general subjects relating to the welfare of the organization, after which the Academy adjourned *sine die*.

Correspondence.

MALARIAL MANIA.

To the Editor of The Medical Record.

Sir:—In the following remarks I shall endeavor to insert the point of the wedge, which, by the repeated blows of abler and stronger minds, shall tear asunder the encircling bonds of fashion which force those who, by the brilliancy of their intellects, should know, and do know better, than to ascribe to malaria the honor, if honor it be, of being the source of all the ills which we mortals inherit. In order that the reader may the more readily understand my own position in regard to this subject, I will state that I accept beyond a doubt, first, that malaria does exist; second, that the malarial poison produces a specific disease; third, that this specific disease may be a complication of other diseases; and, further, I have a growing suspicion, which during the last few months is fast ripening into a conviction, that mental malaria is a prevalent disease, hitherto overlooked, yet none the less present among us. During my observations of some years, the tendency on the part of the rural doctor has been to conceal obscure diseases under the malarial cloak, and not until the indignation of the misnamed visitor has reached so high a pitch as to thrust his entire physique through this unseemly garment so as to be recognized by any layman, has the medical expert laid aside the mask.

Only a short time ago two of my patients were taken to the city for consultation with two of our leading specialists. Case first, an epileptic, was carefully questioned and examined, the place of residence was ascertained, and, with a self-conscious smile, he repeated the word *malaria*. His anti-malarial prescription was written; the medicine was taken by the patient, with the expected result on my part, viz., failure.

Case second: aphonia from acute laryngitis. Similar experience with our specialist, similar treatment, with similar result. Impression made by both specialists on minds of all interested: "examples of malarial mania." The physician in case first assured me that remaining a few hours in the locality where I reside caused him to suffer an attack of intermittent fever; in fact, he believes that passing through the district in an express train has produced such an attack.

A practitioner from a neighboring town, a senior in years, volunteered the advice, that if I hoped to become a successful physician, I must add a large proportion of quiniæ sulphatis to every prescription; and, judging from the liberal use he himself makes of this drug, I am satisfied that he believes what he preaches.

Again, on a recent visit to the examining physician of one of our life insurance companies, his first observation was an examination of the liver and spleen, "for enlargement," he said, "as I lived in a malarial district."

Without wishing to multiply instances of this character, let me say that if we accept the three principles in reference to malaria which are laid down at the beginning of this article, is it not plain that we must have something peculiar in a given case which will call to mind the fact that malarial poison is at work, just as we decide that scarlet fever is present, by its peculiar symptoms? It is not necessary to relate what these symptoms are; we are are all familiar with them, and yet in the two cases noted, aside from the fact that their homes are in a locality where intermittent fever does occur, there was nothing to warrant any such conclusions. In closing, let me remind the city specialists that if they desire to retain the confidence of the suburban doctor, something other than a continual reference to malaria as the source of all disease must be resorted to. H.

SANITARY ADMINISTRATION AND EPIDEMIC DISEASE.

To the Editor of The Medical Record.

Sir:—Not wishing to weary your readers by unnecessarily prolonging the discussion upon this subject, I wish only to answer a few of the statements in Prof. Lyman's paper in the Medical Record of September 4, 1880.

The illustration given by Dr. Lyman of the ravages of measles during the early history of the Sandwich Islands seems to me to have nothing whatever to do with the question of heredity, and to be capable of a very different explanation from that given by him.

My solution of this problem would be, that when epidemics are carried by the whites to ignorant and barbarous natives, unlearned in the proper management of such diseases, knowing absolutely nothing of hygiene or the proper medical treatment of such cases, it can scarcely be a cause of wonder that multitudes are slain.

The failure of heredity as a protection in measles is shown by the fact that severe and fatal epidemics of measles are not unknown even in our own day, as is witnessed by the epidemic occurring in Kiel during the year 1860. Dr. Lyman surely cannot have forgotten how severely our United States Army suffered from this same disease during 1862 and 1863.

A striking illustration of the failure of heredity to protect from epidemic disease is shown in the case of cholera.

In a certain part of India, known as the cholera district, cholera is, and has been from time immemorial, always endemic, and mounds are said to be formed of the bones of the unfortunate pilgrims who perish every year of the pilgrimage. Has the long continuance of this disease lessened its mortality?

The history of small-pox in England and the continent of Europe is also very instructive on that point. For hundreds of years this disease had full sway, and had it not been for the beneficent discovery of vaccination by Dr. Jenner, it would be slaying its thousands at the present day.

I must in this connection again ask Dr. Lyman to explain the reason why inoculation was abandoned, if it be true, as he says, that it is necessary to preserve the virus of epidemics in the community? Inoculation, if Dr. Lyman's theory be true, would seem to be just what is needed, and yet, as we all know, it has been universally abandoned.

Among the North American Indians, especially among the wilder tribes, who refuse to be vaccinated, and treat their small-pox patients by the incantations of the medicine man, small-pox is still a dreadful scourge, and heredity has not diminished an iota of its fatality.

I wish to remind the doctor of the failure of heredity to diminish the mortality from scarlatina in England and the rest of Great Britain, for, as is well known, the mortality from scarlatina is just as great as it was a century ago.

In all zymotic diseases the subtle poisons or germs of each one produces its specific disease, just as infallibly as the planted acorn produces the oak, and never any other kind of tree. I am unable to find a scintilla of evidence to show that any of the ordinary zymotic diseases have been in any respect modified by heredity, but present the same phenomena that they did in the earliest periods, when we have any authentic information concerning them.

Not only is heredity no protection from epidemics, but in some cases the mortality from them is actually increasing instead of diminishing in our day.

Dr. Farr, of England (in the Seventeenth Annual Report of the Registrar-General of England), has shown that the mortality from diarrhœa, summer cholera and diseases of a choleraic character, has been unusually great during the present century; that the mortality from them suddenly rose in 1827, and progressively increased till 1831, and that it still increased till 1838, and has kept on increasing until the present day.

In the bulletin of the National Board of Health (U. S.) for September 4, 1880, page 513, will be found a table showing the mortality for the country of Spain, for the month of June, 1880. This report shows that during the above period, four hundred and seventy nine (479) persons died of typhus fever.

On the same page will also be found an abstract of the mortality of part of the United States, embracing statistics of over eight million persons (8,188,414), with not a single case of typhus fever reported, and the following remark is made at the bottom of the same page: "In comparing this and other reports with those of the United States, the most conspicuous point of difference is the comparative absence of typhus fever in this country, where it is so rare as to give no appreciable death-rate for the whole population.

Now, what is the cause of this exemption from typhus in the United States—is it heredity? Can we suppose that there is anything peculiar in the organization of the people of Spain, that renders them liable to typhus fever whilst we are exempt? Surely not. Heredity and natural selection have just about as much to do with the spreading of zymotic diseases as the "baying of dogs upon the full moon." The simple explanation of this is of course the existence of bad hygiene, and when the same condition of things prevailed in England and this country, we had typhus fever as well as they.

Did heredity save Memphis from being desolated by yellow fever, and why has it escaped this year? Certain sanitarians, not believing in the heredity or natural selection of filth, have partially drained and cleansed unhappy Memphis, and see the result!

Dr. Lyman says in his article (p. 277):

"It is the long-continued weeding out of our communities by disease that has contributed to bring the human race to its present condition."

"A stern and unremitting process of natural selection, permitting only the survival of the fittest, is one of the principal sources of national vigor."

"Just as soon as this process is interfered with, by the misguided efforts of ignorant man, deterioration begins."

"In this connection it is suspiciously significant, that, during the past forty years of sanitary enthusiasm in England, the average duration of life in that country has not increased."

Truly "this is the most unkindest cut of all," and, if it means anything, gives the fair inference from the language used, that the misguided efforts of ignorant men (*i.e.*, sanitarians), in filling cesspools, improving drainage, and supplying pure air and water, are actually increasing instead of diminishing the mortality in England This seems, on the face of it, an astounding statement, and is worthy of inquiry as to its correctness. It is perfectly true that the mortality has scarcely diminished in England during the past forty years, but the Doctor should give the reasons for this condition of things, and not place all the burden of it upon the heads ot unhappy sanitarians.

The first reason or cause to be mentioned for this condition of affairs, is the immense emigration that has taken place from the British Islands during the past forty years. These emigrants are, as a class, in the prime of life and vigor, and their withdrawal from the population necessarily leaves behind them an abnormal proportion of the feeble, the very young and very old, thus increasing the average ratio of mortality.

The second cause and a most potent one, is the vast and alarming increase in the consumption of intoxicating drinks in Great Britain of late years, with the terrible increase of crime, pauperism, and disease which necessarily results therefrom.

Other reasons I might give, connected with the moral and social condition of society in Great Britain, but I have only space to give one (which is believed by good authorities to act more powerfully than any other), and that is the neglect of and wilful disobedience to the laws of health and hygiene, by the people of England. But, in order to show how mistaken Dr. Lyman is, I will only refer him to the sanitary condition of the city of London, England. In that city, as all know, the greatest efforts have been put forth to improve its sanitary condition, and London is to-day the healthiest large city in the world.

Its average annual mortality this year is twenty-three per thousand. Paris, France, has twenty-eight per thousand. Berlin has forty-four per thousand. New York, U. S., has twenty-five per thousand, Washington, D. C., has about thirty per thousand of annual mortality.

The Turk, when asked to improve sanitary matters in order that the people may not be swept away by pestilence, shrugs his shoulders and says: "It is fate; it is the will of Allah." People believing as Prof. Lyman does, calmly say: "Keep still, the fittest will survive." The reasons given in the two cases are very different, but the final result (inaction) is the same.

ROBERT REYBURN, M.D.

2129 F STREET, WASHINGTON, D. C.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from September 26, 1880, *to October* 2, 1880.

IRWIN, B. J. D., Major and Surgeon. Relieved from duty in Department of Dakota, and to report in person to the Lieut.-General Commanding Military Division of the Missouri for duty as Attending Surgeon at Headquarters of that Division, relieving Surgeon Spencer. S. O. 205, A. G. O., September 24, 1880.

SPENCER, W. C., Major and Surgeon. When relieved by Surgeon Irwin to report in person to the Commanding General, Department of Dakota, for assignment to duty. S. O. 205, C. S., A. G. O.

GODDARD, C. E., Major and Surgeon. To report in person at the expiration of his present leave of absence to the Superintendent Mounted Recruiting Service for duty as Post Surgeon at the cavalry depot, Jefferson Barracks, Mo. S. O. 205, C. S., A. G. O.

BROWN, J. M., Capt. and Asst. Surgeon. To accompany Battalion, 16th Infantry, from cantonment on the Uncompahgre, Col., to Fort Garland, Col., and there remain on duty. S. O. 211, Department of the Missouri, September 22, 1880.

BREWER, J. W., Capt. and Asst. Surgeon. To report in person to the Commanding General, Department of the South, for assignment to duty. S. O. 205, C. S., A. G. O.

TREMAINE, W. S., Capt. and Asst. Surgeon. Relieved from duty in Department of the Missouri, and to report by letter, at the expiration of his present sick leave of absence, to the Surgeon-General. S. O. 205, C. S., A. G. O.

WEISEL, D., Capt. and Asst. Surgeon. To report in person at the expiration of his present leave of absence to the Commanding General, Department of the East, for assignment to duty. S. O. 205, C. S., A. G. O.

HARVEY, P. F., Capt. and Asst. Surgeon. Assigned to duty at Fort Snelling, Minn. S. O. 113, Department of Dakota, September 22, 1880.

Biart, V., First Lieut. and Asst. Surgeon. Relieved from duty in the Department of the Missouri, and to report in person, at the expiration of his present sick leave of absence, to the Commanding General, Department of Dakota, for assignment to duty. S. O. 205, C. S., A. G. O. The operation of the above order suspended until May 1, 1881. S. O. 209, A. G. O., September 30, 1880.

Benham, R. B., First Lieut. and Asst. Surgeon. Assigned to temporary duty with escort to working parties on extension of Northern Pacific Railroad, at Camp Houston, D. T. S. O. 113, C. S., Department of Dakota.

Aconite in Rheumatism and Neuralgia.—Dr. D. B. Simmons, of Yokohama, Japan, writes: "I see in some of the later numbers of our home journals two or three notices of the use of aconite in certain forms of rheumatism and neuralgia. From the reading of the articles on this subject, it would appear that their authors had the idea that they were stating *something new*.

"I would state, however, for their information, that an infusion of a native aconite root is in general use by the doctors of this country for these diseases, and is regarded by them as a remedy of great value for their relief or cure.

"As the medicine of Japan is that of the Chinese, the use of this drug in the East no doubt dates back many years, if not centuries."

American Association for the Cure of Inebriates.—The eleventh annual meeting of the American Association for the Cure of Inebriates will be held in New York City, October 20, 1880, at the rooms of the Young Men's Christian Association, commencing at 11 A.M., and continuing two days.

T. D. Crothers, M.D., *Secretary*.

Death of Dr. Eben Hunt.—A member of the Bellevue Hospital House Staff, Dr. Eben Hunt, died very suddenly of diphtheria last month. It is thought that the disease was contracted from a case which he had been visiting. Dr. Hunt was one of the most promising members of the house staff, and his untimely death is greatly deplored. He was a graduate from the academical department of Dartmouth College. He took his medical degree at the University College in this city, and was appointed on the house staff of Bellevue Hospital last spring. This is the second death that has occurred on the staff in the past two years.

Dr. Hunt's remains were taken to Whitehall, Ill., where members of his family live.

The Increase of Diphtheria.—The number of deaths from diphtheria in this city usually runs from thirty-five to forty-five. During the latter part of August and first of September this number increased to sixty-five, and remained between fifty and sixty during the whole of last month. In the week ending August 14th, the deaths were thirty-six. During the next week the number suddenly rose to sixty-five. It was noticed that a strong north-easterly storm had occurred just before this increase, which had made the tides very high. It was also observed that the cases were for the most part situated along the east and west sides of the city, but especially on the east side. In many of the tenement-houses the high tide had flooded the cellars, then receding, had left the floors damp and foul. In addition to this, there was a great deal of filth in or about the houses, noticeably in those that had been infected. There were eleven deaths in one tenement-house, and fourteen in another. By careful disinfection, cleansing, and isolation, as far as possible, as well as by distributing information by circulars to the inhabitants, the Board of Health were able to help in preventing further spread of the disease. It seems now to be decreasing slightly in amount.

Dr. T. M. Franklin, who has been for some time temporarily in charge of the insane asylum on Blackwell's Island, in place of Dr. A. E. Macdonald, the former Medical Superintendent, has been appointed Medical Superintendent by the Commissioners, at a salary of $2,000 per annum.

The Hospital of Oral Surgery.—The Philadelphia Dental College has established, in connection with its dental department, the Hospital of Oral Surgery, in order that its students may be instructed in the surgery of the mouth, as well as in mere mechanical dentistry. A clinic is held under the charge of Dr. Jos. E. Garretson, Prof. of Anatomy and Surgery, and the patients operated upon are kept in the wards of the hospital until able to return to their homes. This is a decided advance in the training of dental students, who, heretofore, have often been deficient in sound medical and surgical knowledge of the mouth and associate parts. There is also connected with the college an anatomical department, where every student may receive instruction in practical anatomy and dissection. The anatomical rooms are under the care of Dr. John B. Roberts.

The Needs of Veterinary Medicine.—In an address delivered by Dr. E. S. Bates, at the opening of the Columbia Veterinary College, in this city, the following statements were made: In the whole United States there are not enough educated veterinarians to supply even one to each large city, to say nothing of the country districts. From every part of the country he, as dean of the college, had received letters asking for good veterinary surgeons, and saying that there were none within 50 miles, none within 100 miles, or none within the State. The graduates of the Columbia Veterinary College had, without exception, secured at once lucrative practices, with incomes amounting even in the first year or two to $2,000, and over. The same was doubtless true of other college graduates. The total value of the stock of the country is estimated at $2,000,000,000. Yet the diseases which so often depreciate the value of this stock are for the most part in the hands of uneducated men.

The State Board of Health held a meeting at Albany, September 22d. The meeting was devoted principally to the consideration of the Buffalo and

Hart's Falls nuisances. The investigating committee reported that the unhealthiness existing in Buffalo, caused by the emptying of sewage into the canal, would probably be remedied by the local authorities by the construction of a new sewer passing under the canal and emptying into the lake. They also reported that the malarial troubles at Hart's Falls can be eradicated by the removal of the nearly stagnant pool, covering about three and a half acres, which is the cause of the evil. This can be accomplished by cutting off the entire area from the Hoosac River, draining the pool and filling in the basin.

Reports for public circulation were ordered to be prepared on the following subjects: Pollution of wells and general house sewage; drainage of towns and villages; offensive trades; dangers of kerosene and the prevention of accidents from its use; diphtheria; proper construction and ventilation of school buildings; small-pox and ventilation; disinfection.

The "Epizooty" has appeared among the horses of this city and is affecting them very extensively. The disease, which is a kind of influenza, has been quite severe in some cases, but there have been no deaths up to the present week, and, as a rule, the attacks are mild. The temperature in severe attacks runs up to 107° or 108°. Some veterinarians are inclined to think that the disease is not the epizooty after all; but this view does not seem probable.

During the present week the disease spread to Philadelphia and affected a large number of horses. It also seems to be extending up the Hudson, there being many cases along the river and at Poughkeepsie.

The Charters of the Philadelphia Bogus Medical Colleges Annulled.—On September 30th the charters of the Eclectic Medical College and of the American University of Medicine were annulled by the courts. This was done with the consent of Dean Buchanan, who has given up the fight. By Buchanan's own confession, over 40,000 bogus diplomas had been issued from the two institutions.

An Epidemic of Diphtheria is prevailing in Bennington, Vt. It began with a few isolated cases during the summer months. Toward the last of September it increased rapidly. Twenty cases were reported in four days. The public schools have been closed.

Removal of Epiglottis.—Dr. Clinton Wagner, of this city, successfully removed the epiglottis, at the Metropolitan Throat Hospital, on Tuesday last. A full report of the case will appear later.

Death of a Faster.—The *London Telegraph* relates the following: On September 13th an inquest was held by Dr. Diplock and a coroner's jury upon the body of one George Alvensbury, a suburban bookseller, who died on the 10th, from the effects of self-imposed starvation. Mr. Alvensbury appears, physically considered, to have been a strangely credulous soul, combining a profound belief in the Tannerian doctrines with a firm faith in the capability of disembodied spirits to administer supernatural nourishment to any fasting man who had faith enough to be assured of their especial protection and favor. Regulating his diet upon these convictions, he rejected all food for an unknown number of days, and, when urged by his landlady and friends to swallow something more solid than spring-water, indignantly replied: "Mind your own business; the spirits will keep me alive." The spirits, however, conspicuously failed to justify his confidence in their nutritive abilities, for he died of sheer hunger and in a frightul state of emaciation last Friday. His demise is rendered memorable by having elicited the following peculiar verdict from the jury which sat upon his wasted remains, viz.: "That deceased died from inanition from want of food, and that it (*sic*) was caused by misadventure."

The Hospital Saturday and Hospital Sunday Association of New York city met and organized at St. Luke's Hospital recently, by the adoption of a constitution and by-laws, and the election of the following board of officers: *President*—George McCulloch Miller; *Vice-President*—Hyman Blum; *Secretary*—The Rev. George S. Baker; *Treasurer*—Charles Lanier; *Executive Committee*—George Jones, the Rev. George S. Baker, Willy Wallach, Dr. Richard H. Derby; *Distributing Committee*—Frederick Sturges, the Rev. Thomas Armitage, Henry E. Pellew, Judge Oliver H. Palmer. The total amount collected last year was $26,000.

Progress of Medical Registration in this City.—Up to October 6th 2,250 physicians had registered at the County Clerk's office in this city. Of this number 24 had registered since October 1st. Reports from various parts of the state show that registration has, as a rule, been quite thoroughly done.

Color-Blindness in the British Medical Association.—In the recent Cambridge meeting of this Association, Mr. Herbert W. Page examined 700 members for color-blindness. Of these 700, there were 12 who were completely color-blind (6 being red-blind and 6 green-blind), and 2 who were incompletely color-blind. In four others the chromatic sense was feeble. All who were thus color-blind knew of their defect, but several who thought they had this visual defect were found to be all right. The examinations of Mr. Page give a much lower per cent. (only 1.71) than has been found by Dr. Jeffries and others. After speaking of the great importance of this examination in calling the attention of medical men to the matter, Mr. Page adds: It should be especially observed that this examination has dealt only with congenital color-blindness, and has taken no account of the color-blindness which is a symptom of various pathological states, notably of the amblyopia due to chronic tobacco-poisoning, which may affect those whose color-perception has been perfectly acute. The existence of such a condition, and it is by no means uncommon, shows how great is the necessity that the examination of railway men and sailors should be made, not only before they enter their respective services, but should be also periodical, and conducted by competent observers, among all who are so employed.

THE PRACTICAL BEARINGS OF THE CRANIAL BONES

In their Relations to Surgery and Medicine.

By AMBROSE L. RANNEY, M.D.,

ADJUNCT PROFESSOR OF ANATOMY IN THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF THE CITY OF NEW YORK.

It is a fact to be regretted that the study of the bony framework should be so often made one of dry detail to the student, especially as it is usually the first subject which, as an aspirant for future medical honors, he is obliged to encounter, and which too often tends to cast a shadow over the bright visions which his fancies had painted, as its perplexities increase.

Sir Charles Bell was in the habit of frequently employing the *living subject* as one of the most efficient means of teaching anatomy, and the points which he thus impressed upon his pupils were furthermore made matters not only of information but of practical interest, by the constant application of the regions discussed to the needs of the physician in his daily associations with the sick.

There are many well-known facts in anatomy which can be taught without the aid of dissection; and many of those well versed in theoretical anatomy, and who could, if necessary, pass a satisfactory examination upon the subject, would utterly fail if compelled to point out upon the cadaver many of the structures concerning which they think themselves familiar. Holden recognized the necessity of this method of demonstration of anatomy upon the living subject, and the need of guidance, which the general profession accepted, when he published his "Surgical and Anatomical Landmarks;" and the success of the effort has justified its republication in one of our popular text-books.

In this article it is my intention to direct attention to such points upon the cranial bones as seem to me capable of being applied to the general practice of medicine and surgery, and I shall endeavor to so apply them as to once more recall scattered points which may have been known and forgotten, and, if possible, suggest means by which this information may be fixed in the memory. It is not to be expected that many original ideas will be presented, as the researches of the greater anatomists have left little to be added, which can help to make this line of study attractive, to which a claim of originality can justly be laid; but much that is old will bear repeating with profit, and many facts which are now scattered throughout text-books will be rendered more useful if compiled in the same article.

The entire skull is sometimes deficient at the time of birth, and the term "acrania" was applied by Béclard to this condition, while the term "anencephalia" was applied by him to those forms of arrested development of the skull where the base only is present.

We find that the *orifice of the ear* corresponds, in the normal skull, nearly to the level of the floor of the cerebrum; so that the height of the skull above this point indicates, in general, the relative amount of brain possessed by an individual. If a string be made to pass from one external auditory meatus to the other over any part of the calvaria, the relative development of that portion of the brain to other portions can be approximately determined.

The *bony skull-cap* is not often symmetrically developed upon its two lateral halves. The frequency of this lack of symmetry may be appreciated by examining the impressions of heads taken by any of our prominent hatters. No two skulls have identical measurements or contour, since, although faces are never alike, mechanical causes may furthermore alter the shape of the head. (This is evidenced to a marked degree in certain Indian tribes, where the heads of the young are mechanically compressed.)

In the head we have the bony framework of the cranium and face covered by its soft tissues. We have its numerous cavities, ridges, depressions, prominences, and foramina. In its soft tissues ramify many of the more important nerves and vessels of the body, while within its cavities are contained the organs which afford the special senses of sight, smell, hearing, and taste, and also the brain with its ganglia, its protective coverings, its vessels, and the nerves by which it performs its various functions.

We find these various component parts so nicely adjusted, as to weight, that the head is almost perfectly balanced upon the spinal column, and so articulated to the trunk as to facilitate the motions of flexion, extension, and rotation without injury to any of its structures.

It is my purpose, in this paper, to treat of those practical points which are afforded by the osteology of the head alone, and to show in how many ways the study of this portion of human anatomy may constantly suggest to the physician new thoughts of value.

THICKNESS OF THE SKULL.

The skull-cap is not of *equal thickness* in all its parts; neither is it of the same thickness in all individuals. It is thicker at the occipital protuberance than elsewhere, and thinnest over the temple. Holden's rule for trephining should never be forgotten: "Think you are operating upon the thinnest skull ever seen, and thinner in one half of the circle than the other."

Trephining the cranium should be regarded as an operation always fraught with danger,* and only to be performed from absolute necessity. The following general rules† should guide in deciding the question: 1st. In diffused injuries to the cranium and its contents all operative interference is unjustifiable; 2d, in simple fractures, with or without depression, operative interference is only called for when marked and persistent symptoms of local compression of the brain exist; 3d, in compound comminuted fractures, with or without brain symptoms, the depressed bones should be elevated and the fragments removed, with the object of taking away known sources of irritation to the membranes, a common cause of encephalitis; 4th, in all cases of local injury to the cranium, of fracture, or other injury, followed by clear clinical evidence of local inflammation of the bone and persistent symptoms of brain irritation or subosteal suppuration, the operation should be undertaken.

Old people often suffer absorption of the diploë, and thus are especially liable to present very thin skulls.

The exterior of the skull-cap *does not correspond* absolutely to the *eminences* and *depressions of the surface of the brain*, but it bears, in some cases, a resemblance to its general outline. Phrenology cannot, therefore, be more than an approximate science.

---

* F. LeG. Clarke.

† T. Bryant.

The thickness of the skull-cap seems to be modified somewhat by the exposure of the head to the effect of the sun, as it is usually very thick in the Egyptian, and in other races where the head is generally uncovered; while it is liable to be very thin and soft in the Persian race, and in other races where the head is covered with a turban from infancy.

TABLETS OF THE SKULL.

The *middle tablet* of the skull-cap (diploë) is abundantly supplied with veins. It is not infrequent that a suppurative phlebitis of these veins is created by wounds received upon the head, even when the scalp is not lacerated, or symptoms of depression of the skull exist. Such an occurrence usually results in disintegration of the blood-clots formed within the inflamed veins, which are carried downward to the heart, and are then thrown into the arteries, only to act as emboli and induce infarction and metastatic abscesses in the various viscera. This probably explains why pyæmia occurs in closed wounds, where no opportunity seems to be afforded for the absorption of any poisonous miasm generated from decomposing pus.

The *tablets of the skull* differ in their relative densities—the inner table being extremely brittle, the middle being spongy and vascular, while the outer table is more yielding and tenacious than the inner. Guthrie * states that sabre-cuts of the head, making only an incision of the outer table, may splinter and depress the inner table over a large extent of surface.

The large number of cases in which the inner tablet has been fractured when the outer table has been uninjured, seems to prove that the brittleness of the inner table, as well as the fact that it is the last to feel the blow inflicted, tends to render it especially liable to fracture. It is, therefore, important that all forms of injury of the head be examined for evidences of local pressure upon, or injury to the adjacent brain-substance, even if no superficial injury to the bone can be detected.

The aperture of exit of a bullet is always larger than that of its entry,† and, in gunshot wounds of the skull, the most damage to surrounding parts may thus be produced at that point.

It is also a well-known fact that some forms of injury to the bony vault of the head are followed by an enormous increase over the average thickness of the skull-cap at the seat of injury, and thus a valuable point in diagnosis is often afforded, where, from defective memory on the part of the patient, or other causes, the seat of former injury cannot be absolutely defined.

GUIDES TO INTERCEREBRAL POINTS OF INTEREST.

A line drawn from the *external angular process* of the frontal bone to the *external auditory meatus* corresponds closely to the level of the floor of the anterior and middle lobes of the brain; while one drawn from the *external auditory meatus* to the *occipital protuberance* corresponds to the level of the base of the posterior lobe of the cerebrum, and to the upper surface of the cerebellum.

The level of the *floor of the brain*, in front, corresponds to a line drawn transversely across the forehead, about one-quarter of an inch above the supra-orbital arch.

The *lowest level* of the *cerebellum* cannot be defined upon the living subject by any given rule. It depends entirely upon the extent to which the occipital fossa bulges into the neck. It is this variation which produces the peculiarities of outline of the back and lower portion of the skull in different individuals.

The *longitudinal sinuses* of the brain may be injured by any wound in the median line of the cranium, above the level of the occipital protuberance, since these venous channels are formed by the separation of the two layers of the falx cerebri.

It was an old practice among the earlier physicians to *leech the nose* to relieve congestion of the brain, and it is recognized that epistaxis is often a great relief in cases of congestive headache. This circumstance is explained by the anatomical fact that the veins of the *frontal sinus* communicate, through the foramen cæcum, with the superior longitudinal sinus of the brain.*

In the tiger, cats, and other of the feline race, the partition between the lateral halves of the cerebrum, corresponding to the *falx cerebri* of man, is not fibrous in character, but is composed entirely of bone.

The *lateral sinuses* correspond, for a part of their course, to a line drawn from the mastoid process to the occipital protuberance, but that portion of the lateral sinus which is indicated by a groove in the postero-inferior angle of the parietal bone, may be defined by measuring one inch from the anterior border of the mastoid process, on a line with the zygoma.

The *tentorium cerebelli*, in man, supports the posterior lobe of the brain and protects it from the injuries which must, of necessity, often occur from concussion, if it rested upon bone. In the carnivora and other mammalia, the tentorium cerebelli is ossified.

SUTURES OF THE CRANIUM.

The *coronal suture* (frontal-parietal) separates the frontal bone from the parietal bone of either side. In the coronal suture, the middle portion is formed by the frontal bone overlapping the parietal, while, at the sides, the parietal bone overlaps the frontal; a provision which manifestly is intended to prevent displacement of the bones.

The *lambdoidal suture* (parieto-occipital) also extends, like the coronal, transversely across the head, separating the posterior borders of each parietal bone from the occipital bone.

The *frontal suture* separates the two lateral halves of the frontal bone until ossification is perfected between them. It is therefore situated in the median line of the forehead.

In one out of every eleven cases of adult skulls found in the catacombs at Paris, the frontal suture remained unobliterated.

The *masto-parietal suture* separates the posterior inferior angle of the parietal bone from the mastoid portion of the temporal bone.

The *squamous suture* separates the parietal bone and the great wing of the sphenoid bone from the squamous portion of the temporal bone. It consists, therefore, of two portions, viz.: the "squamo-parietal" and the "squamo-sphenoidal" sutures.

In the mastoid suture, small isolated bones called "Wormian bones" are chiefly found.†

The *sutures* of the *cranium* are of great practical interest for the following reasons:

1. Because they may be mistaken for a fracture, as was done by Hippocrates himself.‡

2. Because, in any form of injury of the skull, it is

---

† Erichsen: Science and Art of Surgery.

* Quain.

† Leach. This fact is also described by Eustachius and Paracelsus.

‡ Celsus.

not advisable to trephine over the normal situation of a suture.

3. Because they enable us to definitely locate the position of any portion of the head of the child during labor.

The *sagittal suture* runs from the frontal to the superior angle of the occipital bone, and lies in the mesial line of the skull. At either end of it lie the two largest fontanelles, viz., the anterior and the posterior. The edges of the parietal bones which form this suture are very much serrated, except opposite the parietal foramina, where these serrations are much less prominent.[*]

THE NASAL FOSSA.

The *external aperture of the nose* lies on a plane below the bony floor of the nasal fossa.[†] The nose has, therefore, to be pulled upward, to allow of a free inspection of the inferior meatus for polypi or foreign bodies.

Since the perpendicular axis of the inferior meatus is much greater than the transverse, forceps introduced into the nose, for the purpose of removing either a growth or foreign body, should be opened in the longest axis of the nasal fossa.[‡]

The *turbinated bones* serve to afford a large expanse of surface for the distribution of the nerves of smell (olfactory). They are, therefore, studded with grooves and canals, through which the nerves come down from the cribriform plate of the ethmoid to spread themselves out upon the mucous membrane of the nose.

In man, they only form a single curve; but in animals, where the sense of smell is greatly developed, they often make rolls within rolls, like a sheet of parchment which has been rolled together. In the seal, they are arranged as individual and parallel plates, and are of great number, so that 120 square inches of surface has been computed to exist in each nostril.

An arrest in the progressive ossification of the perpendicular plate of the ethmoid bone occasions the deformity known as the "pug nose."

The roof of the nose is extremely thin, being formed only of the cribriform plate of the ethmoid bone, so that perforation of the brain is extremely easy to be performed at this point. The old Egyptians were in the habit of first removing the brain through the nose with an iron hook before commencing the process of embalming,[§] and subsequently the cavity of the cranium was filled with drugs through the same channel.[‖]

An anatomical peculiarity of the skull of the negro race is often exhibited in the nasal fossa, as a *fourth meatus*, which lies above the superior turbinated bone.

The *bony edge* of the *anterior nares* is a guide to the lower orifice of the nasal duct, which appears as a minute slit, about one-quarter of an inch behind the bony edge of the nose, on a level with the inferior turbinated bone. The nasal duct is usually probed, in case the escape of the tears is obstructed from above downward, however, as its lower opening is difficult to reach, especially as it is situated upon the outer wall of the inferior meatus of the nose.[¶]

The *vomer* is not always felt to be in the median line, as it is often deflected toward either the right or left side. Cases are recorded where such an abnormality, when associated with a tumefaction of its mucous covering, has been mistaken for a polypus of the posterior nares, and attempts at its removal have been made.[*]

The *edge of the vomer* may be felt in examining the posterior nares with the finger. To accomplish this, the head must be thrown as far back as possible, in order to bring the upper and posterior part of the pharynx below the level of the soft palate, and the finger should be pushed upward behind the palate, and hooked forward till it enters the posterior nares. This step has a practical value in estimating the size of a plug, (usually one inch long and six lines wide),[†] to arrest nose-bleed, and in the diagnosis of polypi of the posterior portion of the nasal fossa.

OCCIPITAL BONE.

The *basilar process* of the *occipital bone* is within reach of the finger when introduced behind the soft palate until it touches the base of the skull (the position of the patient being the same as when the posterior nares are to be explored). It is often the seat of attachment of polypi[‡] within the pharynx, and a positive diagnosis can thus be made by the sense of touch, if sight or the laryngoscopic mirror detects the existence of such a tumor, and its point of attachment is a matter of doubt.

The upper surface of this process, although situated within the cranial cavity, affords support to the medulla oblongata. This important ganglion does not, however, rest upon the bone itself, since a thin layer of fluid is interposed, like a water-bed, to prevent injury to it in case of concussion being transmitted to the head through the spinal column.[§]

The strength of the ligaments which bind the head to the vertebral column do not alone prevent dislocation of the head, since the *deep cups* of the atlas hold the *condyles* of the *occipital bone* firmly in place.[‖]

The *centre* of the *condyles* upon which the head moves may be defined by a line which shall connect the hips of the two mastoid processes.

The *occipital protuberance*, being the thickest portion of the skull, is seldom fractured by violence received upon that point; but the same force, being transmitted, may create fractures either of the base or anterior portions of the skull.

The *condyles* of the *occipital bone* are much longer than the articulating cups of the Atlas, and thus permit the forward and backward motion of the head; while the *deep fossæ behind the condyles* allow an extra amount of motion in the backward direction, so that vision can be directed perpendicularly as well as in a horizontal direction.

The abnormalities in length of the *styloid processes* of the skull, which are occasionally found, are dependent upon an ossification of the stylo-hyoid ligament.

FRONTAL BONE.

The *orbital plates* of the *frontal bone* are often absorbed in the aged, and large holes in them may be frequently discovered. Their extreme thinness renders any form of punctured wound of the orbit liable to be complicated with injury to the frontal lobe o the brain.[*] The arch of the orbital plate is not uniform; and, if great, the frontal lobes of the brain are proportionably small. In the monkey tribe this is very apparent.

[‖] Quain.

In the frontal bone, after puberty has been reached, the tables of the skull-cap begin to separate; thus leaving a cavity called the *frontal sinus*, whose situation is usually indicated by a prominence of the forehead. It is a point of surgical value, that the frontal sinus may not be always proportionate to this eminence; and, in rare cases, the eminence may be entirely absent, in case the sinus be formed by a recession alone of the inner tablet of the skull. Wounds of the forehead over this sinus may break the skull without injury to the brain. Small insects have been known to enter this cavity through the nose. The sense of pain in the frontal region, which accompanies nasal catarrh, has been explained by some authors as an extension of the inflammation to the mucous membrane which lines this cavity.

Blumenbach mentions the case of a lady (Poulet ascribes this case to Maréchal of Metz) in whose frontal sinus a centipede managed to pass, after entering the nostril. It gave her intense pain, and was expelled alive one year afterwards during an attack of sneezing.[†]

The larvæ of insects, especially those of the horse-fly, not infrequently are found in the frontal cells of animals.[‡]

Sir Charles Bell[§] reports a case, where a patient, who had slept in barns, had a corn insect enter the frontal sinus, and which was discharged eventually as a worm.

Fractures of the skull over the frontal sinus may cause fragments of bone to be discharged by the nose, and a loss of smell is often produced by such accidents. Emphysema of the tissues[‖] about the forehead may be produced during attacks of sneezing or coughing, if the outer wall of the frontal sinus be injured, and air be thus allowed to escape.

In some tribes (especially the Australians), where the frontal sinuses are imperfectly developed, a want of resonance to the voice is produced.[¶]

Musket-balls have been found within the frontal sinuses.[**]

The *enormous air-chambers* in the head of the elephant explain why musket-balls may be shot into the cranium of that animal without apparent injury, unless it happen to wound the hollow at the root of the nose, at which place the encasement of the brain is very thin, or chance to enter the orbit. This arrangement, constituting an approach to a double skull, is a protective one on the part of nature, since the falling of trees, etc., to which danger this animal is constantly subjected, would otherwise be liable to produce fatal injuries.

The extent of the frontal sinuses differs in races and with age. They may reach, in extreme development, a depth of one inch, and extend more than half-way up the forehead.

Wounds of the frontal region are especially dangerous to life for four reasons: first, on account of nerves which may be wounded; second, from the danger of meningeal inflammation; third, from the fact that the frontal vessels, being derived from the same trunks as those of the cerebrum, may induce similar changes in the brain; and fourth, because the shock may create a tendency to inflammatory effusions upon the meninges, or within the ventricles.[††] The danger of this class of wounds was recognized by the ancients, who attributed it to injury of the "Galea Capitis,"[*] which, from its white color, they mistook for nerve-tissue.

PARIETAL BONE.

The *sutures* of the *parietal bone* are wonderfully adapted by nature to prevent displacement inward, since they are levelled upon alternate sides. It is therefore impossible to injure the brain in this region without a fracture having previously occurred.[†]

There are six portions of the cranium where ossification is delayed and where the pulsations of the brain may be felt. These spots are called *fontanelles*, since the brain pulsations were first likened to the bubbling of a spring. The fontanelles are called the anterior, posterior, and the lateral of either side;[‡] and they exist at the points where the angles of the several bones eventually meet. The *anterior* is quadrilateral, and is formed by the two parietal bones and the two halves of the frontal bone. The *posterior* is triangular, and is formed by the two parietal and the occipital bones. The *lateral* are usually nearly filled at the time of birth.

These openings are of value to the obstetrician in determining, by the sense of touch, the position of the child's head during the first and second stages of labor.

TEMPORAL BONE.

On the whole, the skeleton of the temple is thinner than that of the preceding region, and its external and internal periostea adhere to it more firmly, because there are here more sutures, which are united to each other by fibrous bands and emissary veins.

The *mastoid process* is intended chiefly to afford additional leverage to the muscles destined to act upon it.

The *mastoid process* contains numerous cells which communicate with the cavity of the middle ear. It has occasionally to be trephined in cases of suppurative osteitis, in order to afford an exit for the infiltrated pus.

Its *cells* are constantly filled with warm air, which enters the tympanum through the Eustachian tube, and which thus renders the bone lighter than if it were not thus excavated. These cells undoubtedly are an aid to the full development of the sense of hearing, since they increase the space in which the vibrations of the air contained within the middle ear may be diffused.

It was formerly the practice to *open these cells* in the mastoid process as a remedy for deafness, dependent upon obstruction of the Eustachian tube, since, by so doing, air was freely admitted to the cavity of the tympanum. The operation fell, however, into disrepute, from the death of the physician of the King of Denmark (Just Berger), who was himself made a subject for the operation.

The mastoid process transmits through the "mastoid foramen" a vein which communicates with the *lateral sinus* of the brain. This explains why leeches behind the ears relieve congestion of the brain.

The *supra-mastoid ridge* on the side of the skull is so extensively developed in the negro race, as to be possibly mistaken for an acquired deformity.

The *post-glenoid process* of the temporal bone is intended by nature as a protection against backward dislocation of the condyle of the lower jaw. It is much more extensively developed in the negro race and gorilla than in the European.

[‡] Vogel.

The *external auditory canal* is narrowest at about its middle point.[*] For that reason, foreign bodies which enter the ear are apt to be pushed beyond this constriction during attempts at removal, and thus additional difficulty in the extraction is afforded. In addition to this fact, the natural moisture of the ear may cause some foreign bodies to swell, and thus render their removal a matter of great difficulty.

The *temporal fossæ* are largest in the carnivorous animals, as their size depends upon the relative strength and development of the *temporal muscles.* In some animals, the temporal muscle almost entirely covers the cranium.

The *zygomatic arch* is modified, as to its size, in all animals, by the development of the muscles of the jaw and by the character of the teeth which exist. It is most strongly marked in the carnivora, where it is arched both in a horizontal and a vertical direction, so as to afford abundant room for the play of the temporal muscle; while in the ant-eater, which has no teeth, the zygomatic arch is incomplete.

Between the *zygoma* and the ear can be often felt the pulsations of the main trunk of the temporal artery.

BASE OF THE SKULL.

In *fractures* of the *base of the skull,* blood and the cerebro-spinal fluid may flow from the ear of the affected side. If the latter escape, it indicates that the petrous portion of the temporal bone has been fissured, and the dura-mater sheath to the auditory and facial nerves has also been lacerated.

In this form of injury, as well as in diseases of the ear, the facial nerve may be implicated, since it passes through a canal (the aqueductus Fallopii) in the petrous portion of the temporal bone; and this explains why we sometimes have paralysis of the muscles of one side of the face under these circumstances. Pressure on this nerve, at its escape from the bone, as in case of tumors, parotid abscess, etc., may also produce a like effect.

In fracture at the base of the skull, blood often escapes from the nose. This is due to the fact that the air-cells in the body of the sphenoid bone are lined by a prolongation of the mucous membrane of the nose; and any fracture which involves the body of the sphenoid bone is liable to be associated with hemorrhage from the nostril.

Ecchymosis of the lower eyelid is a symptom very frequently associated with fracture of the base of the skull. This discoloration is subconjunctival in character, and appears, as a rule, within the first twenty-four hours after the accident. It may be explained as an infiltration of blood from the nasal cavity into the orbit, or by an escape of blood into the orbit, through the spheno-maxillary fissure, in case some one of the numerous vessels which enter the cranium at its base are involved.

It may also occur if the orbital plate of the frontal bone be involved, or when blood escapes through the sphenoidal fissure into the orbit.

BONES OF THE FACE.

Much of the character exhibited in the face depends upon the superior maxillary and inferior maxillary bones. In them the teeth are inserted, which contribute much to fill out the cheeks and to modify the character of the mouth, while to them most of the muscles of expression are attached.

The orbits are *surrounded,* at the facial margin, by a very strong ring of bone, while its upper wall is as thin as parchment.

The mechanical object of thus protecting the exposed portion of the orbit from injury is also still further shown by the strong ridge of bone which runs from the zygoma. It is thus almost impossible to directly crush in the orbit, except the most extreme violence is used.

The axis of the orbits are so directed that, if prolonged backward, they would meet at the sella turcica. This divergence affords to the eye a range of vision greatly in excess of that which would be afforded were the orbits directed in the antero-posterior plane.

The muscles of the eye are enabled to retract it within its socket, and thus to still further protect it from violence.

Injuries from pointed instruments within the orbit may produce death from injury to the brain.

Modifications in the configuration of the *hard palate* often affect the tone of the voice. On the hard palate can often be felt the pulsations of the posterior palatine artery, which escapes at the inner side of the last molar tooth.[*]

A pin introduced in the centre of the crucial suture of the hard palate would touch five bones, the fifth one being the vomer.

The *septum* between the nostrils is seldom exactly in the median line, and should not be considered as a deformity unless one nostril be seriously occluded.[†]

The lower edge of the *superior* and *middle turbinated bones* can be made visible by widely dilating the nostril. This is of importance in attempting to include the pedicle of a polypus within the grasp of a forceps.[‡]

The *second molar tooth* of the *upper jaw* is a guide to the orifice of the duct of the parotid gland (Steno's), which can be seen in the mouth as a small papilla on the mucous membrane of the cheek.

A line drawn from the interval between the *two bicuspid teeth* to the point of junction of the inner and middle thirds of the supra-orbital arch, will cross the *supra-orbital* and *infra-orbital foramina,* and, if prolonged downward, will intersect the *mental foramen.* This point is of value in dividing nerves for facial neuralgia. The division of the main trunks of either the third, fifth, or seventh nerves, in removing tumors or other operations upon the face, is apt to cause distortion of the features or loss of sensibility.[§] But in nearly every instance, as any deep incision must necessarily divide some portions of the nerves of the part, the surgeon can do little more than bear in mind the importance of avoiding them, if possible, or, at least, of not excising their trunks if they should be divided, as union may possibly restore their function.[‖]

The *last molar tooth* is a guide to the introduction of a tube into the mouth, in case of tetanic fixation of the jaw requiring forced alimentation, since a space exists between that tooth and the ramus of the jaw sufficiently large to admit a tube of moderate size.

The *cavity* of the *superior maxillary bone* (the antrum or[¶] maxillary sinus) is the frequent seat of disease. Within it[**] may be developed either solid or cystic tumors, and pus not infrequently accumulates. The close relation of the different walls of this cavity to important structures give to these growths more than a passing interest.

---

[*] Wilde: Aural Surgery.

[*] Quain.

[†] Gross.

[‡] Watson.

[§] Horner: Special Anatomy.

[‖] H. H. Smith.

[¶] Galen.

[**] Highmore.

If the inner wall becomes expanded, the nostril may be occluded; if the lower wall, the roof of the mouth may be depressed; while the inferior maxillary nerve, which runs above it, may be pressed upon if the upper wall is affected, and the orbit may furthermore be so encroached upon as to greatly displace the eye. If the posterior wall be crowded backward the zygomatic fossa will be encroached upon, and tumors have thus created a marked swelling in the region of the temple.[*] Finally, the anterior wall may become prominent, and thus greatly distort and disfigure that side of the face.

The walls of the antrum are thicker in the child than in the adult, and for that reason the growth of tumors within that cavity will be liable to progress more rapidly after puberty than before. Suppuration of the antrum arises not infrequently from decay of the teeth, or from a failure to remove a nerve within a tooth after it has been killed by caustics previous to filling a cavity, since the putrefying nerve creates gas, which escapes from the end of the fang, and thus creates suppuration in and about the alveolar process.

The antrum is the largest of the air cavities of the head.[†] A large-sized musket-ball has been known to remain loose within it for years, and in some instances such balls have been known to escape through the roof of the mouth.[‡]

Drake reports a case where a woman endeavored to explore the cavity of the antrum through a socket of a tooth with a quill pen, and, to her horror, introduced the whole six inches of its length by its assuming a spiral direction within the cavity, and thus curling upon itself. She sought medical assistance, supposing it had entered her brain.

The *antrum* should be tapped in case of its distention from fluid either within the mouth, at a point situated one inch above the margin of the gum, covering the *first molar tooth*, or, that tooth having been drawn, puncture of the antrum should afterward be made through the socket; or, in case it is deemed important to preserve the teeth, puncture through the canine fossa, as recommended by Desault, or through the molar tuberosity, as recommended by Lemorier, can be performed.

The *nasal bones*, although slight and small in themselves, form an arch of enormous strength, whose buttresses are the superior maxillary bones, and whose centre is supported by the spine of the frontal bone. The feats of supporting great weights, such as a ladder with an adult on the top, as seen in the circuses, attest to the strength of this method of construction.

It is for this reason that fractures of the nasal bones are usually associated with a fracture of the perpendicular plate of the ethmoid bone, and occasionally with a fracture at the base of the skull.

The *lower jaw* in man consists of one bone, but in the serpent it consists of two symmetrical bones joined by an elastic band or ligament, which allows them to be separated in a lateral direction to a great extent. It is by means of this arrangement that the serpent is able to swallow its prey, which is often as large or even larger than its own body.

In man, however, this bone is very strong, so as to perform mastication even of hard substances, and its points for muscular attachment are rough and prominent, to afford the firmest possible union between the bone and the power which moves it.

The *absorption of the sockets* (the alveoli), which is natural in the old, constitutes a disease, when it occurs in youth or middle life. Such an absorption is liable to occur in cases of long salivation, scurvy, or purpura, and a premature age of the jaws is produced.

When the jaws are closed, we see that *each tooth* is *opposed by two teeth* in the other jaw, being an evident attempt on the part of nature to render the loss of any one tooth hardly perceptible in the act of mastication.

Each *external cusp* of the lower teeth fits into the hollows between the cusps of the teeth of the upper jaw, and thus ensure a more perfect adaptation of the grinding surfaces.

The two *condyles*, or articulating surfaces of the lower jaw, are not directed absolutely backward, but are placed at such an angle that, if their long axis were prolonged, they would intersect each other at the anterior edge of the "foramen magnum." This is to facilitate the rotary movements necessary for the mastication of our food.

Each *condyle* of the *lower jaw* can be felt in front of the ear, on motion being attempted. It can be felt to move forward when the mouth is held wide open, and return when the mouth is closed, thus affording the grinding motion demanded during mastication of food.

The *ramus* of the *lower jaw* partially protects the external carotid artery from injury, since the artery enters the parotid gland close to its posterior border.

The *symphysis* of the *lower jaw*, within the mouth, is a guide to divide the genio-hyo-glossus muscle, in case the tongue has to be drawn far out of the mouth to remove tumors of that organ, or in case it is divided as a means of cure for stammering.

The *coronoid process* of the *lower jaw* can be felt at the lateral and posterior part of the mouth. Its inner surface is a guide, in some cases, for puncture of a deep temporal abscess, since pus burrows between it and the tuberosity of the superior maxillary bone.

An attempt has been made to decide as to the character of food indicated by nature for the best nutrition of an animal by the character of his teeth. It does not always hold good, however, as, while man seems adapted to masticate both vegetable and animal food, the bat species have incisors, canines, and molars, and still some are purely frugivorous, while others live entirely on insects. The monkey tribe also have large canines, yet they live exclusively on vegetables.

The *angle* of the *lower jaw* marks a region of special surgical interest, since the temporal, temporo-maxillary, facial, external jugular and internal jugular veins can be found in the immediate vicinity. Hence the necessity of caution in operating in this vicinity.

The *internal angular process* of the frontal bone is used as a guide to detect the reflected tendon of the superior oblique muscle of the eye, which can be felt by pressing the finger beneath this process, and which should be always carefully avoided in operations in the vicinity of the orbit.

THE CRANIUM AS A WHOLE.

Holden, in his work on osteology, lays great stress upon the relative situation of the various *buttresses* of the different regions of the cranium, since, "like all other arches, the cranium transmits a shock toward its buttresses."

---

[*] Blandin: Anat. Topog.
[†] Guthrie: Commentaries, p. 528.
[‡] Jargavay: Anatomie chirurgicale.

Thus, the frontal bone is supported by the malar bones and the wings of the sphenoid; the parietal bones by the temporal bones; the occipital bone by its entering the base of the skull and adjoining the body of the sphenoid.

It may, therefore, be often possible to predict the *direction* of the *course of a fracture*, produced by transmission of a force applied to the vault of the cranium, by a knowledge of the exact seat at which the force was first applied; and, by a thorough familiarity with the surgical bearings of the special cranial foramina, and the parts which lie in close contact with the different portions of each of the cranial bones, to *predict symptoms* which may subsequently be developed.

By far the greater proportion of the blows received by the head are applied to the parietal region. This bone rests upon the temporal bone, which is weakened by the following cavities and foramina: the meatus auditorius externus and internus, the tympanum, the cochlea and semicircular canals, the aqueductus Fallopii, the jugular fossa, the carotid canal, the opening of the Eustachian tube, the Glasserian fissure, and other smaller canals. It is therefore extremely probable that a fracture of the parietal bone will extend in a direction to involve some of these special portions of the temporal bone.

It has been argued in the past, by Malgaigne, Velpeau, and Béclard, that the analogy between the head and a sphere will account for many of the phenomena of transmitted force, producing the so-called "*fracture by contre-coup;*" and since a sphere, when struck smartly, is most apt to break at the point immediately opposite to the point where the blow was received, such an analogy would theoretically indicate a like effect within the skull. Practical observation seems to have proved this, however, to be a fallacy, and the defect in the analogy will account for the error in deduction.

The skull is in no respects a sphere; on the contrary, it can with far more reason be compared to an arch, and all mechanical deductions on the latter basis will approximate far more closely to the facts presented by nature than upon the previous hypothesis. It is the buttresses of the arch, all of which converge toward the body of the sphenoid bone as a centre, that feel, first and chiefly, the effects of transmitted force, and most "fractures by contre-coup" will be found to affect not antagonistic portions of the cranium, but the supports of that portion of the vault which is injured.

VARIATIONS IN THE FORM OF THE SKULL.

An external view of the head may show variations in its form. These may be due either to age, sex, national characteristics, or mechanical causes.

The *skull of the infant* is large in its occipital region, while its frontal region is imperfectly developed, and the face is extremely small in comparison with the skull, being usually only one-eighth of the entire weight.

The sutures are usually separated or imperfectly closed, and the fontanelles are apparent.

In *childhood* the face increases in its relative size, reaching one-quarter to one-third the weight of the skull; and the frontal and parietal regions also develop rapidly, giving the head a more symmetrical appearance.

The *skull of the female* is characterized by the following peculiarities:

1. The bones are individually smoother, lighter, and smaller.
2. The face is smaller in proportion to the skull.
3. The frontal sinuses are smaller than in the male.
4. The parietal region is very large in comparison with the frontal and occipital regions.
5. The jaws are much narrower than in the male.

Camper first pointed out the variations in the *skulls of different races*, and showed the modifications which ensued as civilization advanced. The more important points to which he called attention were as follows:

1. The smallest skulls are found in the Hindoo and the ancient Peruvian races.
2. The largest skulls are found in the Caffre and Scandinavian races.
3. The skulls of all *rude tribes* are characterized chiefly by the following deviations from those of the civilized races:
   (*a*) Prominent temporal ridges.
   (*b*) Extremely wide zygomatic arches.
   (*c*) " " anterior nares.
   (*d*) Extreme length and strength of the jaws.
   (*e*) " " of the incisor teeth.
   (*f*) Obliquity of the incisor teeth to each other when approximated, in contrast to the *right angle* found in civilized nations.
   (*g*) Prominence of the points of muscular attachments.

Among the deviations in form, dependent upon mechanical causes, may be enumerated:

1. Non-closure of the sutures (as in chronic hydrocephalus).
2. Imperfect ossification (as in rickets).
3. Excessive development.
4. Irregularities in shape, dependent upon a premature obliteration of the sutures (synostosis).
5. Acquired distortion, from compression, etc. (as in the flat-head Indian tribe).
6. New growths.

POISE OF THE HEAD AND THE DIAGNOSTIC VALUE OF DEVIATIONS FROM THE NORMAL ATTITUDE.

No part of the osseous system of man affords more striking evidence of his adaptation for the erect attitude than the cranium. The vertebral column forms a right angle with its base and thus affords it a direct support. The condyles, or points of articulation, are situated very near to the centre of its base; by which arrangement little active muscular power is required to maintain it *in equilibrio.* In this respect the human cranium differs from that of other animals, in which the condyles are usually placed much further back, especially in those animals where the head is suspended by an elastic structure (the ligamentum nuchæ) at the extremity of a spinal column which lies horizontally.

The head, as has been observed, consists of two distinct portions, the cranium and the face; the one being intended to contain the brain—the organ of the mind, and the organ of hearing; the other to enclose the organs of sight, smell, and taste. The more the organs of smell and taste are developed, the greater is the size of the face and the greater its relative proportion to that of the cranium. On the contrary, the larger the brain, the greater must be the capacity of the skull, and the greater its proportion to the face.

On this principle, a large cranium and a small face indicate a large brain with a restricted development of the sense of smell and taste; but a small cranium and a large face mark an opposite conformation. This point is of special value to the naturalist, insomuch as it affords him a means of relatively estimating the faculties, instincts, and capabilities of different individuals, as well as of different classes of animals.

Camper suggests a simple rule to estimate the proportion of the cranium to that of the face.

If a line be drawn upward from the side of the chin to the most prominent part of the forehead, it will form an angle with a horizontal line drawn backward over the external auditory foramen from the margin of the anterior nares; the *size of the angle* so formed will indicate the degree of development of the cranium and brain, as compared with that of the face and the organs of sense.

As examples of this, these lines are so nearly coincident in the crocodile as to form scarcely any appreciable angle; while, in the horse, it measures 23°; in the dog, 20° to 35°; in the ourang-outang, 56° to 60°; and in the European adult, from 85° to 95°. Thus, we find man at the top of the scale of all of the animate beings, and distinguished from the rest as well by his external conformation as by his physical and moral attributes and his internal organization.

The head is capable of direct movement only in one of three directions, viz., forward, backward, and a rotary movement. By means, however, of the cervical vertebræ, which have great mobility, the head may also be given a lateral inclination, and the forward and backward movement of the head may be also thus greatly increased. The different attitudes assumed by the head have not only a physiological interest but also a diagnostic value. By permitting a free and unrestricted use of the head, mankind is afforded a *scope of vision* equal to that of those animals, where the absence of such latitude of movement requires that the eye shall have multiple pupils or such a prominence of the eye itself as to permit it to cover all points with distinct vision without motion of the head. Furthermore, were it not for this mobility of the head and neck, *hearing* would also be rendered far less acute in man than in those animals who are provided with larger and movable ears.

The physiological acts of prehension of food and its mastication, the sucking of liquids through a tube, the swallowing of food after mastication, and that part of normal respiration which is performed in the larynx and hyoid region, are all materially assisted by movements of the head.

Much of the grace of movement which characterizes some individuals depends upon the carriage of the head as well as that of the trunk and extremities. The idiot* may often be told by the motions of the head alone.

The attitude of the head may have a diagnostic as well as a physiological value. Thus, in convulsions, the head is usually *inclined to one side*, from the destruction of the proper balance between the antagonistic power of the corresponding muscles on the side opposite those then in active exercise. In hemiplegia the same effect is produced, since the loss of nerve power affects only the muscles of one side. In dislocation of the cervical vertebræ, although an infrequent accident, the head is usually inclined from the mesial line of the trunk; and in glandular swellings and large cicatrices, from burns of the lateral aspect of the neck, a mechanical impediment is often produced to an erect poise of the head, which may demand surgical relief.

The head is bent *forward* in some types of vertebral malformations: in case of large growths upon the neck or shoulders, in emphysema, in the cicatrices of burns affecting the anterior portion of the neck, and in many conditions of the spinal column, muscles, or vessels, which render the erect position painful.

In almost all diseases resulting in extreme dyspnœa,* such as croup, laryngismus stridulous, laryngeal obstruction from foreign bodies, new growths, or paralysis, growths in the neck, asthma, pneumothorax, heart lesions, etc., the head is, as a rule, thrown backward to afford an unobstructed channel for air through the mouth, nares, and pharynx. The same attitude will be also perceived in tetanus, cerebro-spinal meningitis, and brain affections of children.†

As in some cases of deformity, resulting from permanent contraction of the muscles which affect the attitude of the head, a knowledge of the muscles which are involved may prove of service, I append a list of the muscles, which may assist in the various forms of distortion.

THE HEAD MAY BE MOVED

Forward, by	*Backward*, by	*Laterally*, by
Rectus cap. ant. major.	Rectus cap. post. major.	Platysma.
" " " minor.	" " " minor.	Sterno-mastoid.
Sterno-mastoid.	Complexus.	Part of trapezius.
Platysma myoides.	Splenius capitis.	Splenius capitis,
	Obliquus cap. sup.	" colli.
Assisted (when the lower jaw is fixed) by	Trachelo-mastoid.	Trachelo-mastoid.
	Part of trapezius.	Complexus.
Mylo-hyoid.		
Genio-hyoid.		
Genio-hyoglossus.

Certain muscles, which act alone upon the neck, may also assist in displacement of the head from its normal attitude, among which may be chiefly enumerated the longus colli, the scaleni muscles, the levator anguli scapulæ, the omo-hyoid, and some of the deep muscles of the back. The result of the contraction of any of the muscles enumerated must depend entirely upon the associate muscles in contraction, and upon the exciting cause; since, if either muscle acts in common with its fellow of the opposite side, the result will differ materially from that produced by the contraction of the same muscle or muscles acting without its fellow.

156 MADISON AVENUE, NEW YORK CITY.

A LARGE CALCULUS was removed from a patient in the Massachusetts General Hospital, by Dr. Bigelow, a short time ago. Its dimensions were 3¾ × 3½ × 3 inches, and it weighed 6,166 grains (about three-quarters of a pound). The stone was less than three years old, as the patient had been examined at that time. He had been able to work until three months before the operation. Dr. Bigelow at first tried crushing, but after working half an hour he had evacuated only 476 grains. The stone was very hard, and, furthermore, was too large to be grasped by the lithotrite. It was therefore decided to cut. Even then extraction was very difficult, as the patient's pelvis was small and the stone was adherent to the side of the bladder. At last, however, by using Fergusson's lion forceps, and by strongly pressing it down from above the pelvis, it was removed. The patient was much exhausted, but at the time of report, the third day after operation, he had no fever, and was doing well.—*Boston Medical and Surgical Journal.*

CONVERGENT SQUINT.

Cause, Results, and Treatment.

By C. A. BUCKLIN, M.D.

(Continued from The Medical Record, Vol. xviii., No. 4.)

Having completed in a previous issue the consideration of the causes of squint, we will now consider its results and treatment clinically.

Case I.—Little girl, 12 years of age, daughter of Dr. D——. She has a hyperopia of $\frac{1}{12}$, and squinted strongly for three weeks. After hearing the opinion of several specialists, the plan of treatment which was adopted was to keep the fixing eye covered with a shade for a number of hours each day, hoping by thus forcing the child to use the squinting eye to prevent its acuteness of vision from being lost by disuse. The operation of tenotomy was to follow later.

By the use of test glasses I was unable to get any satisfactory results. Upon examination with the ophthalmoscope, hyperopia $\frac{1}{12}$ was easily recognized. Convex glasses No. 12 were given. The squint disappeared immediately. Two years have now elapsed and the child is perfectly free from squint, and finds it only necessary to wear glasses for reading or observing small and near objects.

Case II.—Annie L——; has hyperopia of $\frac{1}{12}$; has squinted badly for four years; came to me to be operated upon. The mobility of the eye toward the nose was not abnormally increased. While observing very small, near objects, the squinting eye made unusual spasmodic movements inward, thus showing that a great amount of accommodation was being produced in the fixing at the expense of position of the squinting eye. I therefore placed convex glasses No. 12 before her eyes, and, to my surprise, the squint disappeared entirely.

In both of the above cases the glasses reduced the amount of accommodation required to the normal standard; therefore, with the glasses on, if the children increased their accommodation by squinting, the increased lens power added to the glass lens made them near-sighted.

Without the glasses they could not see distinctly without squinting; with the glasses they cannot see if they squint.

Green has proposed to treat squint by continued instillations of atropine, thus paralyzing the accommodation. The patients deriving no benefit from trying to accommodate give it up and allow their eyes to remain parallel. I have no doubt but he has had some success with it. I have seen one case where it appeared to be of temporary benefit. If it has a place anywhere it is with children who are too young to wear glasses. It is certainly a scientific fact of interest that complete paralysis of the accommodation should cure squint. My experience has been, that, if the child is old enough to talk, this means of treatment is a pretty sure way of losing your patient.

The paralysis must be complete and must be maintained, if not *complete* the atropine only makes the squint worse. If a sufficient quantity is used to insure complete paralysis of the accommodation, the specific effects of belladonna poison are speedily developed. The parents rush in post haste to a family practitioner, who perhaps berates specialists in general, or they go to one of your good friends who is also an ophthalmologist. He will sympathizingly remark I would not like Doctor No. 1 to treat a child of mine. Doctor No. 1 is regarded in the same light as if he had operated upon the eye and destroyed it, when the only sin he committed was to put atropine in it.

In most cases of squint the internal muscle, by its continual over-strain, hypertrophies, and shortens so that if the accommodation is entirely released the muscle is too short to allow the eye to return to its normal position. *These two* cases, however, illustrate that it *is possible* for squint to exist from three weeks to four years, without the internal *rectus* undergoing organic shortening.

Case III.—Child thirteen years of age has H. $\frac{1}{15}$. Has squinted ten years. She carries pupil of the squinting eye half out of sight behind the nose, when she moves it to the utmost inward. (She should only be able to carry the sclerocorneal margin to the caruncle.) The fixing eye has only a normal amount of mobility inward.

When asked to observe a near object the squinting eye moves spasmodically inward. The muscle has become stronger and shorter from the constant exercise, and the eye cannot return to its normal position without the fixing eye makes a corresponding deviation inward. The acuteness of vision in the squinting eye is one-third as acute as in the other eye.

The above case represents the usual conditions found in a simple case of hyperopic squint.

The only way to treat it is by tenotomy. The way this was done is a fair description of how one should do it till they have had sufficient experience to choose for themselves as to the best method. The eye is held open with a spring speculum at a point where a vertical and horizontal tangent of the cornea would meet; a good firm fold of conjunctiva and subconjunctival tissue is grasped with a fixation forceps, the fold is elevated and cut through with a small pair of sharp scissors (they should cut perfectly to the extreme point). The first point is to be sure that the opening is not too small, and that you are *through* the capsule of Tennon. A blunt hook is now passed through the opening, with the point close on the sclera, pointing downward, passing it pretty well back; the hook is revolved on its shaft, keeping the point constantly in contact with the sclera. If these details have been properly carried out the tendon of the muscle will always be found on the hook. Slight tension is then made upon the hook to separate the muscle from the globe, and the tendon is cut through with the scissors. In our case this was done—the tendon, with its lateral attachments, were divided sufficiently so that the eye could only be carried inward till the edge of the cornea reached the lachrymal puncta. The results were so perfect that three months afterward I was unable to say, from a superficial examination, which was the eye operated upon; there was no scar and no abnormal limitation of the movement of the globe. If the first three cases one operates on are of so simple a nature, he is certain to regard himself as a very clever squint operator.

If the eyes can be made straight, without decreasing their mobility beyond the normal standard, the greatest perfection has been reached. It is, however, sometimes impossible.

Case IV.—Child nine years of age; has squinted for several years; hyperopia one-sixteenth. Mobility of squinting eye less than that of fixing eye, which is very uncommon.

Tenotomy on squinting eye had little or no effect. I next tenotomized the fixing eye and waited till she partially recovered from ether. Finding there was a slight cast remaining the ether was continued, and the tendon of the squinting eye was also carefully divided, I satisfying myself at each step that the mobility of neither eye was abnormally reduced. The result remained a perfect one.

Case V.—Miss M——; slightly hyperopic; squinted for ten years. When she observes a near object, the squinting eye makes strong movements inward. When the eye is at rest there is a decided squint. If she thinks any one is observing her she can generally look perfectly straight. She says I cannot tell always whether my eye is straight or not, but if any one tells me it is not, I can turn it straight. I convinced myself in a few moments that the above was true in every particular. The moment I asked her to look at any object, far or near, the squint came back instantly. Upon inquiry, she acknowledged that when she was holding her eye straight she could not see anything distinctly. To cover the mortification of having a deformed eye she had learned the unusual "*trick*" of relaxing her accommodation entirely, and then by a separate innervation of the external rectus she could hold her eye straight while any one was looking at her. This led her parents to believe for many years that she must outgrow it.

Glasses would not relieve the trouble. Tenotomy was resorted to. The position and motion of the eyes are perfect. A slight granulation is the only means by which one could judge that she had ever squinted.

Case VI. is a simple case of hyperopic squint with hyperopia $\frac{1}{6}$. After a single tenotomy there still remained a slight degree of squint, which entirely vanished as soon as his hyperopia was corrected with glasses. As it is necessary for him to wear spectacles to see well on account of his hyperopia, I think it would be unnecessary to limit the mobility of his eyes any more for the correction of the squint.

Case VII.—A lady, fifty-five years of age. Excessive myopic squint; far point of distinct vision two inches. In attempting to direct both eyes at a very near point both internal muscles became hypertrophied and shortened; consequently, when the optical axis of one eye occupies the position of an eye which is looking in the distance, the fellow eye must converge. She converged one eye nearly as frequently as the other, always fixing with the eye upon which the light fell the strongest, because that eye had the smallest pupil.

She consulted the leading ophthalmologists of this city. The first one, notwithstanding the impossibility of ever placing her eyes in such a position that they could both be directed at any one object they could see, did a double tenotomy for simple cosmetic purposes. No change in the position of the eyes followed the tenotomy.

Another specialist, hearing of the poor success of the first tenotomies, gave her a pair of glasses which, could she have seen through them, would have been of great benefit; but, to use her own words, she had to remove them to tell which way the stage was coming. He declined to operate, and advised her never to allow any one to operate.

I succeeded, with Dr. Pomeroy's assistance, by freeing both internal muscles and stitching both external muscles farther forward, in fulfilling the cosmetic indications perfectly. Her eyes are straight and mobility is good. Although these eyes, since she commenced to squint, never were in position where both eyes could observe the same object at the same time on a corresponding retinal point, consequently she never could see the same object with both eyes without seeing it double. I cannot speak very warmly of an operation which places the eyes in such a position that they cannot both fix on an object which is within their range of distinct vision. This case is no worse off in this respect; neither can it be said that she is any better. If squint is present in near-sighted persons where the far point is far enough away, or can be removed by the aid of glasses to such a distance that it is practical to converge both eyes at it, the squint may be satisfactorily cured with glasses alone, or with tenotomy and glasses.

Case VIII.—A case of myopic squint, tenotomized some years ago in Cincinnati four times. Slight divergence was the result, with double images, from the moment of the last tenotomy. I divided both external muscles, and he was able to merge the two retinal images into one again, thus having binocular vision restored, after having had six tenotomies. This is a very uncommon result, and only illustrates what I said above, that where the far point of distinct vision is far enough away to make it practical to direct both eyes at it, myopic squint is not difficult to deal with. Unfortunately, out of five cases I have met within the past year, in only one of them was the far point of distinct vision far enough away, nor could it be removed with glasses sufficiently to make its correction desirable on any but cosmetic grounds.

Accidents.—It will be seen, in operating for squint, the conditions to be fulfilled are to leave the eye in proper position without limiting its mobility. We are in *hyperopic* squint, where glasses are not to be worn, obliged to so weaken the internal muscle of the squinting eye that the same muscular contraction which formerly existed is not able to divide the eye abnormally inward, but not to so weaken it that when the muscle is perfectly relaxed that the eye wanders outward. The margin which remains between divergence when the accommodation is at rest, convergence, where it is active, is sometimes very small, as the following case illustrates:

Case IX.—Boy twelve years of age; hyperopia one-tenth. After two tenotomies the eyes were parallel. After three months, while observing any object, they remained in proper position, but upon becoming tired, or if his attention was not fixed upon any object, the eye which formerly squinted would wander slightly outward, but always returning when he was observing any object closely. The mobility of both eyes being good a simple tenotomy of both externi will probably remedy the trouble. Where the eye is carried inward from inflammatory contraction of a muscle, and hyperopia does not exist, the difficulties to be overcome are not so great. Here there is a broader margin between the limitation of motion required to keep the eye straight and divergence. After a single tenotomy the eye may refuse to move beyond the median line inward; sometimes it cannot be brought even to the median line. Such an accident can only be remedied by dividing the external rectus, and carefully dissecting out the internal muscle, which must be stitched as far forward as possible. The stitches should be passed under the conjunctiva from the wound above and below the cornea as far as the median line; thus a firm hold of the globe is insured. I never have seen any one who was able to get too much effect from this operation. The rule is, you must get all the effect you possibly can; at least try and converge the eye as far as the lachrymal puncta.

The plan of trying to catch the muscle together with a large fold of conjunctiva with forceps, and bring the whole mass forward, is as unscientific as it is uncertain. In the first place you can never be sure you have the muscle. If you have the muscle you never know whether you have a free end which will attach itself to the globe. Possibly the end is already curled up and attached to the conjunctiva, so that it is impossible for it to become attached to the globe.

You also have a large red fold of conjunctiva which requires years to absorb sufficiently not to be a decided deformity.

The best way is to avoid the above accidents by *insisting* that every eye you tenotomize shall move, at the time of the operation, to the lachrymal puncta. If this is always insisted upon many unpleasantnesses will be avoided. It makes no difference what the objections of the patient or friends are, if the eye has not a desirable amount of mobility the ether should be continued and the over effect should be taken up with a strong silk suture. There is no time better than this time to do it.

Where you operate and do not get enough effect, you certainly have done your patient no harm, which is not the case when you get a divergence.

I have seen two eyes where the vitreous chamber had been opened some years previous, during a squint operation. Such a wound closes without a suture. I should, however, prefer to unite the edges of the wound with a suture.

An accident which quite frequently happens is extravasation of blood in the *capsule of Tennon*. It usually makes a very black eye, but is not attended with any other unpleasant result. I have seen a hemorrhage so extensive from a simple cut through the conjunctiva that the tissues of the orbit swell sufficiently to force the spring speculum from the eye. The orbit appeared as if it were filled with an immense melanotic cancer; the retro-bulbar pressure was so great that the sensation of light vanished for several minutes. I lighted a lamp and the patient was unable to see it in a dark room four feet away. In from two to five minutes the vision began gradually to return. No unpleasant effects were experienced. In four weeks all traces of extravasated blood had disappeared.

RECAPITULATION.

1. All persons squint who can see by so doing and cannot see without. The degree of their hyperopia or the strength of their internal muscles can be what they may.
2. Every squinting eye that is not due to *paralysis* of a muscle can be straightened.
3. Never fail to satisfy yourself before leaving an eye you have tenotomized, that the mobility of the eye is sufficient.
4. The use of one eye is usually lost in convergent squint. Consequently its earliest symptoms should receive prompt attention.

The cases which I have reported to more practically illustrate my text, have been selected from a collection of over two hundred cases of squint personally examined by myself.

247 East Fiftieth Street.

Bromide of Ethyl is still used by Dr. Levis in his private practice. He considers it safer than chloroform and more agreeable than ether.

SUPPRESSION OF URINE FOR NINE DAYS.

Acute Diffuse Suppurative Nephritis Following Scarlatina.

By GEORGE F. BATES, M.D.,

NEW YORK.

The patient, Henry S. K——, a child of four, was attacked with scarlatina on the seventh of January. The first symptoms of the malady were vomiting and diarrhœa. Two other children in the family were ill of the same disease, one having been attacked two days before, the other on the same day as the patient above, and all with the same initial manifestations of vomiting and purging. In each case the rash developed within twelve hours. Henry had the disease in a mild form, the highest temperature having been 101¾° on the day the eruption appeared. The rash had entirely disappeared on the sixth day, and the patient was out of bed on the tenth day. From the sixteenth to the twenty-second of January the patient's temperature was normal, appetite only fair, complained of feeling tired, looked "kind of forlorn," as his mother expressed it, but otherwise appeared to be convalescing.

He was kept in the room in which he had been ill, was warmly clothed, and the temperature of the room was carefully regulated. The treatment, up to this time, had been: in a warm bath every evening; internally eight minims of the tincture of the chloride of iron, and one drachm of a saturated solution of chlorate of potash every three hours, and one grain of the tannate of quinine, in the form of a lozenge, three times daily.

On Wednesday morning, January 22d, the patient awoke complaining of nausea. After a light breakfast he was dressed, but felt too ill to sit up, and was put back in bed. He was given a dose of the spirits of nitrous ether, and soon thereafter voided two ounces of urine. From then till night he passed urine twice, half an ounce each time. The temperature at 11.30 P.M. was 100¾°. The urine passed was found loaded with albumen.

By the use of the hot-water baths free diaphoresis was induced, and two drachm doses of the bitartrate of soda were followed by active catharsis. A flaxseed poultice was applied over the loins, and frequently renewed. On the day following, the 23d, patient vomited several times. The temperature in the evening at eight was 101¼°. On the three succeeding days two hot-water baths daily were given, and the soda was continued; the sweating was profuse, and frequent watery stools were voided. The catheter was passed daily, and at no time was there obtained as much as a drachm of urine, and testing this small amount, it was found to contain seventy-five per cent. of albumen. A separate vessel was used at each stool to catch the urine should any be passed, but there was none. The temperature on the morning of the 24th was 103¼°. It ranged from this down to 99° for three days, being irregularly high and low without reference to the hour of the day, or any appreciable cause for its wide variation.

On January 26th, in the afternoon, the respirations became difficult and superficial, in number sixty per minute. I called Dr. Leaming in consultation. A hot-air bath was constructed, the temperature kept at 100° to 105°, and the patient placed in it. By Dr. Leaming's advice, five grains of the mild chloride of mercury were given. Cups were applied over the chest and kidneys, and one-half grain powders of digitalis were administered every six hours. On the following morning his condition was somewhat better, the respirations were forty-eight per minute, and deeper. The hot-air bath was kept up during the day, but as the skin did not seem to respond commensurately with the heat applied, a hot-water bath was ordered, and after the bath the patient was wrapped in blankets, and the diaphoresis desired was the result. The breathing became much improved, forty per minute, and not labored. The bowels acted freely, but the nausea and frequent emesis continued. A diet of milk had been ordered, but a small portion only was retained, and there was substituted whey with brandy and gin on alternate hours. The brain remained perfectly clear, and there was no anasarca.

On January 28th, Squibb's fluid extract of digitalis was substituted for the powder, and given in one-drop doses every four hours; also the oleoresin of cubebs in emulsion, minims three every three hours. Spongiopiline, soaked in an infusion of digitalis, ℥i. to ℥xx. was placed over the hypogastrium and over the loins. Pupils normal, and responded readily to the light. Bowels and skin active.

On the 29th, during the day there was no material change. During the night preceding $\frac{1}{16}$ of a grain of morphine was given to allay restlessness. In the evening, at six o'clock, patient's breathing became labored and slightly stridulous, and it was necessary to elevate his head to ease the respiration.

At 11 P.M. I found the patient's breathing stertorous, and accomplished only with the intensest effort, and there was every evidence of immediate dissolution, with the one exception of the pulse, which still continued full and forcible.

On the morning of the 30th, to my surprise I found the boy living, and breathing with comparative ease: respirations forty per minute. Ordered the body sponged with bay rum and warm water every three hours. The brandy, gin, and digitalis were continued. Called Dr. Gillette in consultation. Percussion revealed the right kidney at least enlarged. By Dr. Gillette's advice, the body from the axillæ to the hips was completely enveloped in one large flaxseed poultice. Temperature at 10 P.M., 102½°.

On the morning of the 31st the temperature at eight o'clock was 103¼°; at 3 P.M., 102½°, respiration 36, pulse 120, and at eight P.M. the temperature was 103½°. I used the battery with the induced current, placing the positive pole over the lumbar region, and the negative pole over the hypogastrium, at three, six, and eight P.M., and for twenty minutes each time. During the day the patient lay prone, with the head thrown back.

At 11 P.M. the boy died without a struggle. The patient's mind had been clear from the commencement of the disease till death, save only a dulness of perception during the last twenty-four hours, due solely to exhaustion; he had no convulsions; there was no coma. From the 22d of January till his death, on the 31st, there was not secreted a half-ounce of urine altogether. As before stated, the catheter was passed daily, and every precaution taken to verify the abolition of the kidney's function. There was no œdema of the connective tissues, nor was there any effusion into any of the serous cavities. This latter condition can be accounted for by the persistent catharsis and diaphoresis induced. The exhalations from the body, however, had not the slightest urinous odor.

On the first of February, the day succeeding death, the abdomen was opened. The peritoneal cavity contained only the normal amount of serum. The intestines were distended with gas. The bladder was shrunken to the size of a small English walnut, and hard to the feel like the uterus. The kidneys were enlarged from two to three times their natural size, and no appreciable difference the right from the left. On cutting through their capsules a dark brownish liquid gushed forth, the liquid having no odor of urine. This liquid separated the capsule from the cortex by a perceptible interval. The capsule was entirely free save at one or two points, where it was bound down by inflammatory adhesions, and an attempt to peel it off at these points resulted in tearing away the substance of the cortex. The surface of the cortex showed numerous bright red points between which were whitish areas of suppurating and necrosed tissue. On cutting into the parenchyma, the pyramids were found nearly normal, but the cortical portion was dotted throughout with innumerable minute points of suppuration. Numerous infarctions from three to five lines in diameter were found, and in the bodies of some of these a bright red dot, as of an obstructed blood-vessel (thrombus). Around these infarctions, and around the bases of the pyramids (the arterial arcades), were white margins of suppuration, a line in width. The kidneys were such as are pathologically termed "surgical kidney," as found after death from pyæmia, or the urethral fever following urethrotomy, differing only in this; the suppurative process was diffused throughout the cortical substance of the kidneys, instead of being limited to portions of both organs. By the microscope, much of the kidney structure showed no traces of the uriniferous tubules, and the tubules, where existing, were found to have undergone fatty degeneration of their epithelial cells.

Progress of Medical Science.

The Cure of Cancer by Radical Operations.—In the *Deutsche Zeitschrift für Chirurgie* (vol. xiii., p. 134–166) Prof. Kocher, of Berne, publishes a report of twenty-nine operations for cancer. Five of these were partial pharyngotomies, fourteen were cases of excision of the tongue, and ten were cases of rectal excision. Four cases terminated fatally, three in consequence of septic processes, and one owing to accidental hemorrhage. Of the remaining twenty-five, nine may be looked upon as radically cured.

Kocher's method for the extirpation of the pharynx consists of a combination of the methods of Langenbeck and Gussenbauer. He favors extensive cutaneous incisions. Crico-tracheotomy is a necessary preliminary operation. In two cases Kocher secured an efficacious "tamponade" of the trachea by introducing, during profound anæsthesia, a suitable carbolized sponge into the larynx. The incision which he practises is an angular one, and proportionate in its extent to the amount of glandular participation in the morbid growth. He begins his cut in the median line, or directly below the angle of the mouth at the maxillary margin, and extends it down to the hyoid bone, and thence backward to the anterior border of the sterno-mastoid muscle. From this point he again proceeds upward along the posterior border of the ramus of the inferior maxillary as high as the pinna of the ear, and downward as far as the larynx. This flap is then turned back and temporarily fastened by suture to the facial skin. Now the large vessels are found by preparation along the anterior border of the exposed sterno-mastoid; then he works his way to the great cornu of the hyoid bone, and along the anterior belly of the digastric muscle to the margin of the maxillary bone, and backward to the angle of the jaw. The lingual and facial arteries must be ligatured, of course. Now the larynx is filled with a tampon. After this, he finds his way through the mylo-hyoid muscle on the inner side of the maxilla to the mucous membrane, which is incised at this point. The finger can now be readily introduced into the mouth and pharynx, and the exact limits of the cancerous tumor ascertained. The operation is then continued along the hyoid bone, and proceeds thence to the tongue. The lateral and posterior pharyngeal walls are easily separated from below, whereas the soft palate can be reached from the buccal cavity. Antiseptic dressings are strictly enforced. The same Listerian rigidity is applied to the excision of the tongue and operations on the rectum. As a preparatory treatment for rectal operations Kocher allows only fluid food for two weeks before an operation, and also insists on daily irrigations of the rectum during this time. The irrigations immediately preceding the operation are made with borated or salicylated water.—*Centralbl. für Chir.*, August 14, 1880.

An Epidemic of Favus Affecting Simultaneously Cattle and Children.—Dr. Gigard reports the occurrence of this epidemic in a village called Nantoin, in the Canton Côte Saint André. Porrigo favosa had existed for several years in the village, but the inhabitants had been heedless of its presence. Many cows were suddenly affected, and at the same time the disease manifested itself among the children. The original culprit, according to the writer, was a calf, which in a somewhat roundabout way communicated the disease to the village cows, and hence to the children.—*Lyon médical*, Aug. 15, 1880.

Treatment of Nasal Polypi by Injections of Chloride of Zinc.—The parenchymatous injection of aqueous solutions of chloride of zinc has been successfully tried by Dr. Ingels (*Annales et bul. de la Soc. de Méd. de Gand*, July, 1880), in cases of nasal and naso-pharyngeal polypi. After alluding to Dr. Barthelemy's recent experience in a case of this kind, the writer communicates his own observations, three in number. The first case related was that of a lady, sixty-six years of age, who had suffered for many years from the presence of a naso-pharyngeal polypus of the fibroid variety. The senses of taste and smell were quite abolished, and her respiration was embarrassed. Previous attempts at operative treatment had invariably been the occasion of alarming hemorrhage. A final examination, in consultation with a colleague, revealed a gangrenous patch upon the tumor, just behind the velum palati. It was therefore determined to assist the process which nature had seemed to indicate, and for this purpose a saturated aqueous solution of chloride of zinc was injected, by means of a suitable hypodermic syringe. Similar injections were repeated at intervals of two weeks, and numerous eschars were thus formed. The detachment of these produced a palpable diminution in the size of the tumor. It was also attacked from the nasal openings, and here, also, good results were obtained. The second case passed from under Ingels' observation before definite results of the injections, only two in number, could be ascertained. This patient had complained of much pain after each injection, and it was probably owing to this circumstance that he failed to reappear. The last case, showing the most complete success, was that of a strong man, about thirty years old. This case, however, also demonstrated that these parenchymatous injections are by no means entirely harmless, for immediately after introduction of the fluid, the man had a severe and prolonged attack of syncope His complete recovery from all untoward symptoms only took place on the third day after the operation. A cyanotic patch which had formed on his forehead remained even some time longer than this. Dr. Ingels explains these manifestations by an assumption of extreme vascularity in the tumor, and by the direct entrance of the chloride of zinc solution into an engorged vessel. The blue spot on the forehead would thus be the result of impeded venous return, due to the presence of an obstructing clot.

A New Method for the Operative Treatment of Prolapsus Ani.—Prof. Kehrer, of Giessen, Germany, has devised a new method for the treatment of prolapsus ani, and reports two successful cases with the same. After briefly alluding to the ordinary methods now in vogue, and commenting upon their frequent inefficiency, he proceeds to explain how he was led to attempt the new method. This was by the simple consideration of a rubber ring, which, owing to frequent over-distention, has ceased to act in a proper manner. If a knot be tied into such a ring, or if a loop of it be secured by a string, its former action will be restored. This simple principle he applied to the over-distended sphincter ani in cases of prolapse. That is, he folds together a portion of the sphincter, and after excision of its mucous covering secures the folds by means of a firm suture. Thus a portion of the ring is eliminated, and the calibre narrowed correspondingly. In the two cases which were subjected to this operation, a speedy cure took place.—*Deut. med. Woch.*, Aug. 14, 1880.

On Papaïne.—The digestive ferment of *carica papaya* has received this name from Bouchut and Wurtz. The latter contributes to our knowledge of the drug in a communication to the "*Répertoire de pharmacie*." He finds that it possesses a composition of an albuminoid substance. When purified by the subacetate of lead, the following additional qualities were ascertained. It is freely soluble in water, dissolving in less than its own weight of that fluid, just like gum. When shaken, this fluid forms an abundant froth. Ordinary impure papaïne, when dissolved in water, sometimes leaves an insoluble white residue. On boiling, the clear solution becomes turbid, but does not coagulate like albumen. When allowed to stand it also becomes turbid, owing to the formation of low organisms. Hydrochloric acid causes an abundant precipitate, which redissolves in an excess of the acid. Nitric acid forms a precipitate of yellowish flakes, which likewise redissolves in an excess of acid. Ordinary phosphoric acid and acetic acid cause no precipitate; but the metaphosphoric acid does. Other reactions are given, which all tend to show the albuminoid nature of this substance.

Its action on albuminoid bodies is similar to that of the pancreatic ferment called trypsine. It rapidly dissolves large quantities of fibrin, even in fluids of neutral reaction. M. Wurtz has also been able to extract from the juice of *carica papaya* a saponifiable greasy substance, and a crystallizable nitrogenous principle, which remained undissolved in the fluid from which the impure papaïne was precipitated—*Annales et bull. de la Soc. Méd. de Gand*, July, 1880.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, October 16, 1880.

MEDICINE IN THE UNITED STATES, AS OTHERS SEE IT.

In a book recently published in London, entitled "Medical Education and Practice in All Parts of the World," we get a very candid, though not entirely accurate picture, of the condition of medicine in this country. The opinion of the author, Dr. Hardwicke, is that medicine here has been in a most scandalous condition, from which it is only now beginning to emerge. He seems to think, and no doubt there are many with him, that up to the past summer bogus colleges in the United States were as thick as atmospheric germs in the imagination of a Listerite, and were quite as active in producing an ichorous discharge of quacks and impostors. In speaking of the recent decree of the French government requiring all foreign medical men to pass an examination before receiving license to practise in France, he says: "All foreign physicians, whether graduates of the bogus universities with which, until lately, the United States abounded, or of such first-class universities as exist in Europe, were included in the sweeping fiat" of the government. And further, in introducing the subject of medical education and practice in this country, he says: "Until lately the condition of medicine in the United States was very bad indeed. Universities were established all over the country, and degrees sold in open day with the coolest effrontery." The author then devotes seven pages to the recent exposure of the Philadelphia bogus colleges, going into the minutest particulars of the downfall of those lamented institutions. There is no doubt that Dr. Hardwicke thinks medicine in the United States, prior to the misfortune of "Dr." Buchanan, to have been clouded in worse than Cimmerian gloom. Things have been and are bad enough with us, but we feel inclined to resent the ignorance which would spread the idea that this is the home of diploma-shops, and that bogus medical colleges are here the rule.

The diploma traffic in the United States has mainly been confined to two cities, Philadelphia and Cincinnati. There have been some degrees sold in this and other cities, but not many. On the other hand, the cities of Germany have done considerable business in this line also. There are very good reasons for believing that just now the fatherland is manufacturing more degrees than are turned out in America. We trust that Dr. Hardwicke, in any future editions of his valuable work, will give less prominence to what has been, after all, the smallest, because the most easily remedied, of our educational evils.

In the subsequent details which he gives regarding medicine in the United States, some very instructive facts may be found. The author states that, in going over the various statistics regarding medical education and practice, he could make this generalization: in proportion to the height of the educational standard at the universities and medical boards will, as a rule, be found to correspond the stringency of the laws affecting the medical profession.

Thus, in countries or states where the medical examinations are incomprehensive and irregularly conducted, the medical laws are elastic, defective, or absent. When medical education is lax, medical legislation is deficient and quacks abound.

According to Dr. Hardwicke's rule, then, the unhappy condition of medicine in this country is due, primarily, to the weakness of the medical colleges. The states which he enumerates as having no medical laws whatever are: Arkansas, Colorado, Connecticut, Indiana (which state is stigmatized as particularly bad), Iowa, Kansas, Mississippi, Minnesota, North Carolina, Oregon, Tennessee, Texas, Vermont, and West Virginia, fourteen in all. In addition to to this must be included the District of Columbia and all the Territories.

In many other states the laws regulating medicine are not much better than none at all. In Maine, for example, a student can hardly graduate without breaking the statutes because of their contradictions.

The proposition that bad medical colleges and licensing boards are the chief source of the evils in medical practice must be applied with considerable reservation to the United States. It would be worth while, however, for our medical teachers to ponder over the statement that bad medical colleges beget bad medical legislation, and that begets quackery.

PSYCHOLOGY AND THE BABY—THE DEVELOPMENT OF MIND IN THE INFANT.

Most of the studies that have been made into the constitution of the human mind have been directed to that of adults, either sane or insane. Of late some investigation has been made into the intelligence of the lower animals. A recent work of a thousand pages, on "Mind in the Lower Animals," by Dr. W. L. Lindsay, gives evidence that we will have, some time, a comparative psychology.

But perhaps the most fruitful field for psychological investigation is that of infants and children. A recent writer in a contemporary review, commenting on this, says: "The psychological analysis of a single child is worth more than a whole menagerie; he who knows well the mind of a little boy or girl is already an expert in psychology." This is a field, however, which has been least of all investigated, though so close at hand that every parent can be something of a psychologist if he choose. Some indication of what a little careful observation can bring out is found in an article which has recently appeared from the pen of Professor W. Preyer, of Jena. We propose to give a few of the observations which he has made. If the facts are not all new, the professor's method of studying babies will, at least, prove novel to many.

This study must begin, he says, with the observation of the movements and sensations of the child; we must then note the development of the different senses, the formation of speech, and the effect of all these things in awakening the intelligence of the child. Movements begin first; they occur *in utero;* they are not reflex from peripheral sensations, but are the evidence of a superfluous nervous and muscular energy.

The first manifestation of voluntary motion occurs when the infant begins to hold up its head. Attempts to do this were noticed in the fourteenth week, and after four months the head was kept well balanced. Next after the head, the upper part of the body was balanced; and the full power to sit up was acquired at the tenth month.

Ability to stand was, in the cases studied by Prof. Preyer, gained suddenly at the end of the first year. The movement of grasping sometimes takes place at a bound. A pencil is grasped mechanically, when put in the hand, in the first quarter-year, but the action is wholly reflex. The first voluntary attempt to take hold of an object was observed in the seventeenth week. This first grasping was at once followed by many others of similar character. The child does not show self-consciousness, a knowledge of itself as an independent person, until after the fifth quarter-year.

The sensibility of the skin of a new-born child is very low. We may stick needles into its nose, lips, or hands, without its giving any sign of discomfort. The eyes of new-born children close, when they are touched, more slowly than at a later period, and they do not close at all when wet in the bath. An increase of sensibility may be noticed in one or two days after birth. Prof. Kussmaul has shown that all new-born children can distinguish strong tastes. Taste, indeed, seems to be the first sense after that of sight, which affords clear perceptions to the baby. It is the first which gives occasion for the exercise of the faculties of memory and judgment. Infants distinguish odors very early, but to what extent has not been ascertained. Some animals born blind are guided to their food—the mother's milk—by this sense. Some odors, as tobacco-smoke, have been found unpleasant to young animals; others, as that of camphor, agreeable.

All infants are deaf at birth because the outer ear is as yet closed, and there is no air in the middle ear. A response to a strong sound is observed, at the earliest, in six hours, but often, not for a day or two. The awakening of the sense may be observed by the irregular muscular movements and blinking which a loud noise occasions. No other organ contributes so much as the ear to the intellectual development of the child. This is shown by the intellectual backwardness of those born deaf compared with those born blind. The sense of hearing becomes early developed, so that the child soon distinguishes the different tones of those about him.

Light is at first unpleasant, and the infant shuts his eyes when brought to it. Brightness and darkness can alone be distinguished. The motions of the eyes are wholly unregulated. There is no real symmetry of movement before the first six days. The first perceptions are those of light. The child turns his head to the window within the first week. It is three weeks, however, before the eyes will follow a light that is moved before it.

The stupid expression on the child's face does not leave it until the second quarter-year. The face then begins to grow more human and spirited as the power is gained of regarding objects with a steady, independent look. The faculty of accommodation is then developing. The power to distinguish colors follows that of intelligent attention. Children all prefer light and bright colors. But they can rarely distinguish them by name before the beginning of the third year.

The recognition of form, size, and distance, comes on slowly. It must be helped by the sense of touch. In the third year children will show ignorance of size, and inappreciation of distance. In the first month no notice is taken of the swiftest approach of a person's hand to the mouth, and the act of blinking, which is evidently acquired, does not take place till the third month.

The study of the growth of the faculty of speech has been pursued by Prof. Preyer with especial industry. He has set down upon paper every expression and sound that could be represented in writing, uttered by a child during its first two years. He informs us that at first only the vowels are heard. Even in the first five weeks, however, these sounds are so diversified as to express many different feelings of the child. Thus, according to Prof. Preyer, the periodically broken cry, with knit eyes, denotes hunger; the continuous whine, cold; the high, penetrating tone expresses pain. Prof. Preyer heard the consonant *m* during the seventh week; in the seventh month the consonants *m, b, d, n, r*, and rarely *g, h*, and *k* were distinguished. Very imperfect imitations of sounds were heard in the sixth month, and at this time voices began to be distinguished by the child. Great progress is made in the imitation of sounds after the third half-year, and the powers of articulation become well developed by the fourth half-year.

These are some of the observations that are given us. Very many of the professor's statements are based on but few observations, and it is very evident that there is a wide field for further study, and much that can be learned which will be of value in the education of children as well as to pure psychology. It might be in the interests of science to commend matrimony to young men ambitious of psychological study.

Reviews and Notices of Books.

CHIRURGIE ANTISEPTIQUE. Principes, Modes d'Application et Résultats du Pansement de Lister. Par le Dr. Just Lucas-Championnière. Deuxième édition complètement refondue avec 15 figures dans le texte. Paris: J. B. Baillière et Fils. 1880.

ANTISEPTIC SURGERY. The Principles, Modes of Application, and Results of the Dressing of Lister. By Dr. Lucas-Championnière.

DR. C. is the editor-in-chief of the *Journal de médecine et de chirurgie pratiques*, and also surgeon to the Maternité of the Cochin Hospital. He has had a wide personal experience, and, being a diligent worker and close observer, his opinions are well worthy an attentive consideration. While we cannot accept all his antiseptic teachings, we have, nevertheless, read with interest the work which embodies them. Divested of some of its Gallic enthusiastic colorings, the book before us is an earnest plea for the universal adoption of "antiseptic," even if not strictly Listerian, dressings.

The work is appropriately inscribed to Mr. Joseph Lister, and the author "hopes that it will enable its readers to realize the greatness of the progress which surgery owes to him" (*i.e.*, Lister). In the introduction the writer points out how profoundly the surgical methods of the present day have been modified and transformed by the progress of antiseptic doctrines. After allusion to the reception which Lister's method was accorded in various countries, we are told that in France at least there is now no prospect of its being superseded by other methods. "Purulent infection has vanished as a complication to be dreaded wherever this method is followed. Erysipelas has become a rarity. Astonishing regularity of reparation, rapidity of the healing process —two phenomena of the greatest importance—are no longer exceptional occurrences; they take place commonly —yes, constantly." These are almost literally the words of the enthusiastic Listerite, and similar passages abound throughout the volume.

The antiseptic method is so well known here that it seems needless to follow the author in his description of all its details. We will, however, indicate the contents of each chapter, thus enabling the reader to judge of the extent and scope of the volume, and the thoroughness with which the subject is handled. There are thirty-four chapters. Of these the first deals with the past progress of surgery, the methods now in use to defend wounds from the injurious effects of atmospheric contact, occlusion dressings and antisepsis in ancient and modern times, and the method of Lister.

Chapter II. contains an account of the theoretical views which form the foundation of the use of antiseptic dressings. Of course, the "germ theory" here receives a goodly share of the author's attention. On page 23 we are plainly told that, "in order to succeed, the surgeon must be perfectly convinced of the truth of the germ theory." Now, it so happens that we are acquainted with many surgeons who are by no means "perfectly convinced," and whose results would creditably compare with those obtained by Dr. Lucas-Championnière. It seems a difficult matter to reconcile this apparent discrepancy with perfect credence of the author's emphatic statement. The following chapter gives a very satisfactory description of the various details essential to the "only original, true" Lister dressing. We are taught how to destroy germs before the operation, during its progress, and after the operation, the only wonder being that, after this wholesale germicidal onslaught, there are any surviving germs left to threaten the life of the next patient.

In the next chapter we receive instruction concerning the management of "old wounds, with or without fistulæ." We are also told how to apply antiseptics to "wounds in the vicinity of natural openings." An aqueous solution of chloride of zinc is recommended for the latter purpose.

"Boracic acid and non-irritant dressings, ununited wounds," forms the title of Chapter V. Boracic acid, we learn, may be advantageously substituted for carbolic acid in cases where the "cutaneous susceptibility" to the latter is inconveniently great.

Then comes a chapter explanatory of the proper time when to substitute ordinary for antiseptic dressings. We know all about that here. In the seventh chapter "sutures and the reunion of wounds, superficial and deep sutures, compression by carbolized sponges," are successively disposed of.

The subject of drainage is next considered. This, we are not surprised to hear, plays a "rôle capital." We are surprised to hear, however, that "it is the surgeon's object to reduce drainage to a minimum" (p. 88). Now, hitherto it was our belief that if there was one thing more useful than another in the antiseptic method, this was thorough and prolonged drainage. We almost fear that our previous belief will not be materially altered by Dr. C.'s dictum.

Chapter IX. is on antiseptic pulverization (*i.e.*, the spray). From the illustrations in this part of the work, we infer that the American atomizers are somewhat less complicated and formidable in appearance than the French apparatus; and perhaps they will be found equally serviceable, barring a certain mysterious tendency to occasionally explode without previous notice, though even this unexplained leaning toward explosiveness is rapidly becoming traditional.

"Catgut and its uses, ligature, drainage, suture, osseous tampons," are dealt with in the next chapter, and the author then turns to "the results of the method as regards the phenomena of reparation," discussing at some length the "absence of suppuration." He also briefly refers to the commencement of his experiments in this direction, which showed the absence of germs in all the antiseptic dressings submitted to his examination. On page 129 we find an incomplete list of French surgeons, who follow with more or less strictness the antiseptic method. Suyon, Verneuil, Panas, De Saint Germain, Le Dentu, Terrier, Perrier, are the names of those cited.

The most important part of Chapter XII. contains statistics with regard to some of the earlier antiseptic operations. Lister, Saxtorph, and Volkmann are cited in this connection.

The following chapters are devoted to a consideration of the special methods to be employed in certain operations. Autoplasties and the extirpation of tumors situated in the soft parts are treated of in Chapter XIII.

Compound fractures and wounds resulting from firearms come next; then follow osteotomy, rachitic curvatures, genu valgum, articular fractures, and resections for pseudarthroses.

In Chapter XVI. amputations and exarticulations are discussed. Then come "accidental and surgical wounds of the joints," followed by "articular resections."

Chapter XIX. is on abdominal surgery—strangulated hernia, laparotomy, ovariotomy, Cesarean section and the operation of Porro, finally, hepatic cysts, are each in turn considered. Of course all these operations are described only in so far as it is necessary to explain the manner in which Listerism is carried out in connection with them.

The following chapter contains an account of antiseptic surgery in relation to operations on the female organs of generation. Nine pages of this chapter are devoted to the subject of "*accouchement aseptique*," the author strongly condemning repeated carbolic injections immediately after delivery. He insists, however, with equal emphasis, on carbolized "hands" on the part of the accoucheur, and "*l'antiseptie de tout le personnel qui entoure les accouchées.*"

Ligation of the blood-vessels, the radical cure of varicosities, and varicocele, are the subjects of Chapter XXI. Then comes the "treatment of abscess—acute and chronic," followed by a chapter on "empyema." Next we find a brief reference to operations on the testicle, and the radical cure of hydrocele by Volkmann's method. Operations on tendons are then alluded to, also trepanation, and then comes Chapter XXVII., with a short but good account of the "treatment of ulcers by cutaneous transplantations."

Ocular surgery has a chapter by itself, and this is followed by a statement of the good "influence of the antiseptic method on the healthiness of hospitals."

In Chapter XXX., carbolic acid poisoning is considered, the writer making rather light of the toxic properties of phenol. Nussbaum's potion, supposed to be antidotal to the acid, is given as follows:

℞. Sulphate of soda	5.0
Water	150.0
Syrup of raspberries	25.0

M. S.—Two tablespoonfuls every two hours.

Naturally enough, a work of this kind would be incomplete without some reference to the "objections to and disadvantages of the antiseptic method." Accordingly, we find Chapter XXXI. devoted entirely to this purpose, nor need it surprise us to find an enthusiastic Listerite inclined to judge leniently the various faults with which the method has been reproached.

Chapter XXXII. tells us how to act in cases when the essentials of Listerism are not on hand.

The last chapter but one contains a detailed enumeration of everything that is needful to properly effect the various antiseptic dressings, and the concluding chapter is an incomplete "bibliographical index."

The Transactions of the Medical Society of the State of New York for 1880. Syracuse, N. Y.: The Standard Printing Company.

The volume contains 682 pages, of which sixty are occupied by the proceedings of the annual meeting, forty by communications on various medical, surgical, and hygienic topics, over one hundred by the lists of the state and county medical societies, and the remainder by an appendix containing the bylaws of the society, the system of medical ethics, and a compilation of the various state laws relating to medical matters that have been passed since 1806. The appendix is a valuable contribution for reference. The usual care displayed by the secretary of the society is manifest throughout the volume, which reflects credit upon both the Committee of Publication and the publishers. It will make an indispensable addition to the library of every medical man who wishes to keep apace with the progress of one of the largest and most active medical societies in this country. It is true that many, if not all, of the papers have appeared in the various medical journals of this and other states; but that fact, instead of detracting from, should enhance the intrinsic value of the volume, because it shows that the communications are of a high order, and well worthy of preservation in book form.

Address Delivered before the New Hampshire Medical Society, on the Etiology, Nature, Causes, etc., of Diphtheria. By T. J. W. Pray, M.D., President, June, 1880.

This address is a very full and exhaustive discussion of the subject of diphtheria. On all the mooted points regarding this disease, the writer shows thorough information and excellent judgment. He inclines to the belief that most cases of croup are diphtheritic processes; he doubts the local and bacterial origin of the disease; and he classes diphtheria among filth diseases. In treatment, no especial plan is advocated, but the various methods employed by the highest authorities are given. The monograph will be found useful for study or reference.

On the Affections of the Middle Ear During the Early Stages of Syphilis. By F. R. Sturgis, M.D.

Three cases are related, illustrating the way in which secondary syphilis sometimes affects the middle ear. The diagnostic points in this class of cases, Dr. Sturgis believes to be absence of acute inflammation and the infiltrated condition of the tympanum.

Pregnancy Vomiting. By J. Marion Sims, M.D., LL.D. Reprinted from the *Archives of Medicine*.

Dr. Sims writes on the above subject with two objects: he relates a case of pregnancy vomiting in which a resort to Copeman's method produced a miscarriage, this being the first reported instance of its so doing. He also gives the full details of a case which came under his charge in Paris eighteen years ago, and regarding which he has since been much misrepresented in Parisian medical and social circles. Dr. Sims gives an endorsement of the efficacy of Copeman's, Jones's and Grailly-Hewitt's methods of treating pregnancy vomiting, when they are properly applied.

The Mechanical Treatment of the More Common Abnormal Conditions of the Foot. By Dr. Charles Frederick Stillman.

This small pamphlet contains a description of the condition and indications for treatment in weak ankles, inverted feet, and talipes varus. For each of these affections Dr. Stillman has devised some special mechanical appliances for which he claims superior advantages.

The Yellow Fever Quarantine of the Future, based upon the Portability of Atmospheric Germs, and the Non-Contagiousness of the Disease. Read at the Seventh Annual Meeting of the American Public Health Association, November 20, 1879. By Henry Fraser Campbell, A.M., M.D.

Dr. Campbell argues against the present system of coast and inland quarantine as being unnecessarily clumsy, oppressive, and inefficient. He presents a simpler plan, based on the assumptions that yellow fever is an exotic disease and not contagious, in the ordinary way. Dr. Campbell's arguments are well stated, and his plans for quarantine have received endorsement from experienced health officers. So far, however, as it depends on the assumption that yellow fever is purely an *exotic* disease, he will not find medical opinion going heartily with him.

First Decennial Report of the Manhattan Eye and Ear Hospital. October, 1879.

The Manhattan Eye and Ear Hospital has had the best talent of the city on its medical staff, and it has done excellent work during the past ten years. It is exceptionally fortunate in having a large number of its medical officers on the government board. The hospital received a gift of $25,000 from Hon. E. D. Morgan last spring. In April, it began to erect a $90,000 building on Park Avenue. We sincerely trust that the funds for the completion of the structure may be supplied. Nine thousand dollars have been contributed since the work began.

Cases of Leucocythemia. By R. P. Howard, M.D. Reprinted from Montreal General Hospital Reports. 1880.

The author relates four cases of leucocythemia which recently came under his notice. Post-mortem and microscopical examinations were made in each case. The marrow of the long bones was also examined, and in two cases presented evidences of hyperplasia, such as is asserted by Neumann, Waldeyer, and others to be characteristic of a certain variety (the myelogenous) of leucocythemia. Dr. Howard discusses very fully this question of the possibility of a myelogenous leucocythemia, and shows that the evidence, so far, is against it. The cases related in the pamphlet before us are admirably worked up and make a valuable contribution to the literature of leucocythemia.

Report on Outbreak of Enteric Fever at Possilpark. By James Christie, A.M., M.D.

The point of interest and importance in this report is given on page 16: "By this outbreak," says Dr. Christie, "we had an absolute demonstration that milk acts as a medium for the communication of the infective *virus* of enteric fever; that the infective *virus*, if present in soiled clothing, may gain access to milk through washing operations in a dairy farm; and that the period of incubation of enteric fever is fourteen or fifteen days." The details of the investigation which led to this conclusion have chiefly a local interest.

Diagnosis of Malignant Tumors of the Upper Jaw. By L. McLane Tiffany, M.D.

In elucidation of the above subject three cases are related, and the operations for the removal of the tumors described. In one case, preliminary laryngo-tracheotomy with Paquelin's thermo-cautery was employed, and the operator speaks highly of the additional facility with which his work was done.

A Case of Unilateral Excision of the Larynx, Hyoid Bone, and Base of the Tongue. By Dr. A. G. Gerster.

The operation here detailed was upon a man aged fifty, suffering from a sarcomatous tumor. This involved the entire right wall of the pharynx, the base of the tongue on the same side, and the tissues of the corresponding side of the larynx, including the epiglottis. The removal of the growth was effected by first removing half the larynx and hyoid bone. The operation was carried through without any trouble or accident, tracheotomy having been first performed. The patient, on recovery, was able to talk in a hoarse voice and to swallow. The account of the operation will be instructive to surgeons who have occasion to do anything of a similar character.

History of United States Marine Hospital Service. By John B. Hamilton, M.D., Supervising Surgeon-General.

This history is a reprint from Appleton's Annual Cyclopædia for 1879. It is a narrative of the gradual growth of the Marine Hospital Service from the year of its creation, 1798, to the present time. Much labor and research have evidently been expended in making the history a full and accurate one.

The Ophthalmic Use of Quinine, and its Therapeutic Action. By A. Sibley Campbell, M.D., Augusta, Ga.

Dr. Campbell's view of the therapeutic action of quinine is, that it is a vascular tonic, restoring the tone of the vessels and enabling them to contract. In this way it dispels blood-stasis and may prevent inflammations. It is particularly valuable after operations on the eye, combined with topical applications of atropia and ergot. Dr. Campbell's use of quinine is not new, and his confidence in it is overrated.

◆

Asylum Mortality and Non-Restraint.—The influence of modern improvements in asylums and in the treatment of the insane, in diminishing the mortality and prolonging the lives of lunatics, is (says the *British Medical Journal*) very clearly brought out by Dr. Cassidy, in the recently issued annual report of the County Asylum of Lancaster. The average annual death-rate in that institution in the decennium 1829 to 1839 was 21.58 per cent. of the average numbers resident. From 1839 to 1849 it was 11.24 per cent.; from 1849 to 1859 it was 9.89 per cent.; from 1859 to 1869 it was 8.93 per cent; and from 1869 to 1879 it was 7.62 per cent. The first great reduction took place at the period when Mr. Gaskill abolished the restraint system. Dr. Cassidy's statistics should be well pondered by those reactionists who now suggest the reintroduction of restraint into asylums.

Reports of Societies.

THE AMERICAN GYNECOLOGICAL SOCIETY.

Fifth Annual Meeting, held in Cincinnati, September 1st, 2d, and 3d, 1880.

Wednesday, September 1st—First Day—Morning Session.

Pursuant to adjournment, the Society convened in the city of Cincinnati, on the first day of September, and was called to order at 10 A.M., by the President, Dr. J. Marion Sims, of New York.

The following Fellows responded to the roll-call: Drs. Fordyce Barker, W. H. Byford, S. C. Busey, A. Dunlap, G. J. Engelmann, G. H. Lyman, T. A. Reamy, A. R. Jackson, R. S. Sutton, Robert Battey, J. R. Chadwick, H. F. Campbell, T. M. Drysdale, W. T. Howard, T. Parvin, J. C. Reeve, J. M. Sims, H. P. C. Wilson, and J. W. Underhill.

ADDRESS OF WELCOME.

After the calling of the roll, Dr. T. A. Reamy bade the Fellows and the invited guests welcome to the grasp of the hands, the friendship of the hearts, and the hospitalities of the homes of the medical profession of Cincinnati.

MEMBERS BY INVITATION.

The following gentlemen were, on nomination by the Council, invited by vote to participate in the discussions during the sessions of the Society: W. W. Dawson, W. H. H. Mussey, Thomas Wood, J. H. Tate, W. H. Taylor, J. Trush, C. D. Palmer, John Murphy, David Judkins, James T. Wittaker, A. J. Miles, William Corson, A. E. Dandridge, C. O. Wright, W. T. Brown, A. T. Keyt, P. S. Connor, and G. Brahl, of Cincinnati; John Henderson, of Covington, Ky.; A. F. Erich, of Baltimore; Chas. Sheppard, of Grand Rapids, Mich.; E. C. Gehrung, of St. Louis; and G. W. H. Kemper, of Muncie, Ind.

The first paper was read by Dr. Robert Battey, of Rome, Ga., and entitled

WHAT IS THE PROPER FIELD FOR BATTEY'S OPERATIONS?

The author took the same position he took when, in 1872, he commenced the operation, namely, that the operation was never to be one of election.

In deciding whether or not he should advise the operation he asked himself three questions.

"1. Is this a grave case?

"2. Is it a case incurable by other known resources of medical and surgical art? and

"3. Is it curable by the menopause?"

If all were satisfactorily answered in the affirmative, he regarded the case as a proper one for the operation known as Battey's. If either question could not be answered satisfactorily, he regarded the case as one in which the operation was not justifiable.

TWO CASES OF ANTERIOR DISPLACEMENT OF THE OVARY SIMULATING INTERNAL INGUINAL HERNIA—BATTEY'S OPERATION

was the title of the next paper, which was read by Dr. G. J. Engelmann, of St. Louis.

Within a short time he had observed two cases of anterior displacement of the ovary that simulated inguinal hernia; in one the ovary was removed, in the other not, on account of the approach of the menopause. In one case, therefore, the menopause was produced artificially, in the other it was left to nature. In both cases, diagnosis, prior to Dr. Engelmann's treatment of inguinal hernia had been made, and a truss had been applied.

In the first of Dr. Engelmann's cases it seemed that the menopause was established by the removal of one ovary, although that point could not yet be absolutely determined, because of the recent date of the operation. The ovary was not enlarged. The right ovary was not removed, and Dr. E. regretted that he had allowed it to remain, because it was possible that the nervous symptoms that still continued might have been checked by so doing. The woman recovered without an unfavorable symptom. She had menstruated twice since the operation; once five weeks after, and once at a subsequent interval of six weeks, but the discharge was scanty.

The discussion on the papers by Dr. Battey and Dr. Engelmann was opened by Dr. Fordyce Barker, of New York, who remarked, with regard to anterior displacement of ovaries, that he had met with three cases. For himself, he could not conceive the possibility of any fall or shock of the kind mentioned, producing displacement of an ovary, and he questioned whether the displacement was not a congenital one, and that the fall aroused a congestion or subacute inflammation that became exaggerated extremely at the time of menstruation.

With reference to the therapeutical study of the subject, in one of the cases he placed the patient upon the use of bromide of potash and hyoscyamia, with beneficial results.

Dr. Barker then related the history of a case that illustrated how severely the nervous system might be affected by disturbances of the ovaries.

Dr. H. P. C. Wilson, of Baltimore, regarded Battey's as one of the most growing surgical operations of the present century. He was particularly struck with the additional class of cases in which it was recommended, namely, certain cases of amenorrhœa.

Dr. W. H. Byford, of Chicago, related the history of a case that illustrated the effect produced upon a fibroid of the uterus by the removal of the ovaries. The case was one in which Dr. Trenholme, of Canada, removed both ovaries for the cure of a uterine fibroid and reported as entirely successful. The patient is now under Dr. Byford's care in the Woman's Hospital of the State of Illinois, at Chicago, and the tumor still remains in the situation as described by Dr. Trenholme before the operation. He believed that, in all cases in which the operation was required, the ovaries are diseased. The discussion was continued by Dr. Dunlap, of Ohio; the President; Dr. Wood, of Cincinnati; Dr. Drysdale, of Philadelphia; and Dr. Jackson, of Chicago; all favoring the operation in proper cases.

The President announced as

The Committee on Nominations: Drs. F. Barker, of New York; G. H. Lyman, of Boston; and H. P. C. Wilson, of Baltimore; and as

The Auditing Committee: Drs. W. H. Byford, of Chicago; and R. S. Sutton, of Pittsburgh.

First Day—Afternoon Session.

The first paper was read by Dr. H. P. C. Wilson, of Baltimore, and entitled,

OVARIOTOMY COMPLICATED WITH PREGNANCY.

"What shall be done with a large ovarian tumor co-existing with pregnancy? What shall be done when it is a large, simple cyst? And what when it is a compound tumor, solid or fluid?" When the tumor is large and wholly cystic, he had been taught to tap from time to time until pregnancy had terminated, and then perform ovariotomy.

When the tumor was compound and the fluid predominated largely over the solid or semi-solid portion, he had been taught to follow the same plan of treatment.

When the tumor was entirely solid, so that it could not be so reduced in size, ovariotomy or the induction of premature labor were the only resources left when there was no longer room in the abdominal cavity for the pregnant uterus and the ovarian tumor.

From these views Dr. Wilson dissented. If, in a pregnant woman, an ovarian tumor was entirely cystic, he advised removal in preference to repeated tappings. When a compound tumor did not have firm adhesions, he would select ovariotomy rather than repeated tappings for the safety of both the mother and the child.

If, in either of the above conditions, the woman, with one or more tappings, might be successfully carried to the termination of pregnancy, in all probability she would be left in a worse condition for a successful ovariotomy, on account of the adhesions that would probably be originated.

When the tumor was solid or semi-solid, or both, and so large that it did not leave room in the abdomen for both itself and the expanding uterus, tapping was out of the question, and he would perform ovariotomy in preference to inducing premature labor.

Dr. Wilson then gave the history of his case in which the mother recovered, and was subsequently delivered of a healthy child, which was still living.

The paper being before the Society, Dr. A. Dunlap, of Springfield, Ohio, remarked that he had *three* cases in which ovarian disease was complicated with pregnancy, and in *two* cases abortion was produced before ovariotomy was performed, and both patients recovered. He was inclined to believe that abortion was likely to be produced by the ovariotomy and if abortion did occur, the woman would probably die. With reference to adhesions after tapping, he did not regard them as especially unfavorable for ovariotomy. Dr. Dunlap was also opposed to the small incision, even if no adhesions existed, because he believed the great success in ovariotomy depended upon proper cleansing of the abdominal cavity, and in order to do that properly, a free incision was necessary. He favored the production of abortion and the subsequent performing of ovariotomy.

Dr. Jas. R Chadwick, of Boston, spoke of surgical non-interference in these cases, and based his remarks upon three cases that had fallen under his observation during the last winter.

Dr. Robert Battey, of Rome, Ga., referred to four cases in his experience which had been let alone, and all terminated fatally. In three, the symptoms were such as indicated rupture of the ovarian cyst. In the fourth case, abortion was produced, and the woman died a few days subsequently.

Dr. Dunlap remarked that, in cases in which the patient was comfortable, it was well enough to allow her to remain without interference until forced to do so.

Dr. W. H. Byford, of Chicago, referred to two cases in which he had tapped the cyst, in one three, and in the other six or seven times, and carried the woman safely to the termination of pregnancy, both mother and children living. With reference to producing abortion, he believed it to be a mischievous practice.

The President referred to the successful case quoted by Dr. Wilson, and also to a case in which rupture of the cyst occurred, yet the woman went safely to the completion of her pregnancy.

With reference to non-interference, he was satisfied that the ovarian tumor should not be interfered with when simple and not larger than twice the size of the fœtal head; but when they became large, he was satisfied that operative procedure was the safest course to pursue.

The paper was further discussed by Dr. Sutton, of Pittsburg, Dr. Erich, of Baltimore, and Dr. Dawson, of Cincinnati.

UTERINE MASSAGE AS A MEANS OF TREATING CERTAIN FORMS OF ENLARGEMENT,

was the title of a paper then read by Dr. A. Reeves Jackson, of Chicago. It contained an analysis of 277 gynecological cases obtained from hospital and private practice. In 194 there was enlargement of the uterus from various causes, and of those there were 179 in which the enlargement was due to causes other than polypus, sarcoma, and carcinoma, such as sub-involution, hyperplasia, etc., etc.

In each of those 179 cases, almost every variety of treatment that has been devised had been employed, such as astringents, caustics, pessaries, abdominal supporters, hot-water douches, together with such general treatment as seemed appropriate.

The class of cases in which massage was applicable was limited; in some it was positively injurious, and much judgment and tact were necessary in the selection of cases suitable for its employment.

The kind of cases in which it may prove useful was the following: When the uterus was low down, large, tender, spongy, doughy, etc., that condition was usually associated with hyperæmia, and *massage* would be expedient unless contra-indicated by other circumstances.

The histories of several cases were then read, which showed that some of the patients were markedly benefited, others less so, and still others received no benefit whatever from the manipulation.

The paper was discussed by Drs. H. F. Campbell, of Augusta, Ga., and T. A. Reamy, of Cincinnati, who dwelt upon the *modus operandi* of the method.

Dr. J. W. Rosebrugh, of Canada, was then elected an invited guest, after which the Society adjourned to meet at 10 A.M. on Thursday.

Thursday, September 2d—Second Day—Morning Session.

The Society was called to order at 10 A.M. by the President.

The first paper was read by Dr. R. S. Sutton, of Pittsburg, and consisted of the report of

A CASE OF CATALEPTIC CONVULSIONS CURED BY TRACHELORRHAPHY.

Mrs. C., aged thirty-eight years, had borne four children; never miscarried. Her last labor occurred August 19th, 1872. None of her labors could be termed preternatural. Her disease began, as was shown, after a laceration of the cervix uteri.

A very large amount of cicatricial tissue was removed, and the patient made a good recovery.

The paper was discussed by Dr. Wilson, of Baltimore, and the President.

Dr. W. H. Byford, of Chicago, then read a paper entitled

EXTIRPATION OF AN ENCEPHALOID KIDNEY.

The patient was admitted and treated in the Hospital for Women and Children in Chicago, and he was indebted to Dr. Mary H. Thompson, house physician, for the history of the case and the notes subsequent to the operation. A female patient, æt. 39, German, and the mother of six children. The tumor weighed four and a half pounds, and upon microscopical examination by Prof. Danforth, was diagnosticated as encephaloid of the kidney. The patient was discharged in July, 1880, apparently healthy.

The paper was discussed chiefly with reference to differential diagnosis by Drs. Chadwick, of Boston; Jackson, of Chicago; Dunlap, of Springfield, O.; and Drysdale, of Philadelphia.

Dr. H. F. Campbell, of Augusta, Ga., then read a paper on

THE VALUE OF QUININE IN GYNECIC AND OBSTETRIC PRACTICE.

As to the supposed abortional effects of quinine, the author of the paper commenced by saying that, at a period not very remote from the present, the medical journals of this country contained frequent papers discussing the oxytocic properties of quinine. "Abortions, miscarriages, and premature births were strongly charged to its administration." To this opinion in regard to the action of quinine, after an observation of nearly forty years, he conscientiously gave an unconditional denial. Of course he spoke of a judicious and prudent use of the agent.

Instead of withholding quinine, in the fear that it might produce abortion or premature labor, it was to be given conscientiously and in efficient doses, *to prevent abortion;* for, in obviating the paroxysm of malarial fever and its wide-spread perturbations, we brought the woman out of peril, and secured her from many possible calamities; the one to be most dreaded being the superinduced abortion.

Dr. Campbell's paper gave rise to discussion, which was opened by Dr. Fordyce Barker, of New York, who referred to the use of quinine for quickening and rendering more efficient labor pains, without being oxytocic, the influence which it exerted in preventing abortion, and in controlling convulsions dependent upon malarial poisoning.

Dr. Murphy, of Cincinnati, believed that quinine did not excite uterine contraction, hence was not an oxytocic; yet it was a most efficient agent in awakening uterine contractions in certain cases of inertia of the uterus.

The experience of Dr. Reeve, of Dayton, O., upon this point, corresponded with that given by the author of the paper, and the speakers by whom he had been preceded.

The paper was further discussed by Drs. E. C. Gehrung, of St. Louis; J. M. Rosebrugh, of Canada; Bates and T. A. Reamy, of Cincinnati; and W. T. Howard, of Baltimore.

ANNUAL ADDRESS BY THE PRESIDENT.

The hour having arrived, the President, Dr. J. Marion Sims, of New York, called Dr. W. T. Howard, First Vice-President, to the chair, and then proceeded to deliver the annual address, which was chiefly a plea for liberalizing the constitution and by-laws of the Society.

After congratulating the Fellows upon the success that had attended their labors during the last four years, the hope was expressed that the strife to maintain the Society's well-established reputation would be vigorously continued. The President then reviewed briefly the history of the organization, remarking that it came into existence just at "the fulness of time," and was the outgrowth of necessity. A worthy and brilliant tribute was then paid to the memory of Atlee and Peaslee, and from that point he proceeded to consider how the boundaries of the Society could be enlarged and its professional character elevated and dignified. With that object in view, he urged several radical amendments to the constitution and by-laws, the most important of which were the following:

1. To extend the membership to one hundred.
2. To provide for transferring from active to honorary fellowship.
3. To provide for electing candidates by the Society, instead of the council.
4. To strike out the requirement that candidates shall submit an essay as a test for membership.
5. To provide for a council consisting of five or seven members, which shall act independently of the other officers of the Society.

"Looking at ourselves as others see us," there was no doubt that there was a large element of discontent outside of the Society, but the proposed amendments he believed would so change the character of the organization, that its work, which all had so much at heart, could be carried on to the highest degree of success.

The Secretary announced an invitation to visit the Cincinnati Hospital, after which the Society adjourned to meet at 3 p.m.

Second Day—Afternoon Session.

The first paper was read by Dr. G. J. Englemann, of St. Louis, on

THE INSTINCTIVE (OR NATURAL) AND PHYSIOLOGICAL POSITION OF WOMAN IN LABOR.

The author of this paper had studied his subject in the following manner:

First, with reference to the position occupied by women in labor among nations of the past, especially those of the highest and best civilization.

Second, with reference to the position in labor among the savage races of the present day.

Third, with reference to the movements of women and the position they involuntarily assumed in the agonies of the last throes of labor, when, to the exclusion of every other feeling, they were controlled largely by instinct. In this work he has been greatly aided by the Smithsonian Institution and by army surgeons, who had sent out circulars to Indian agencies, etc. He had endeavored to classify the different positions according to the axis of the body:

1. Standing or erect positions; 2, the inclined position and its varieties; and 3, the horizontal, or recumbent position.

The paper was illustrated by a large number of drawings, representing the positions assumed by women of the red, yellow, and black races, together with others of civilized races.

The conclusion which the author of the paper reached from his most exhaustive investigation was, that the fully recumbent position upon the back was inimical to safe and rapid labor, and that it retarded labor.

He believed we should advise that, in the early stages of labor, the woman should be permitted to follow her own instinct with reference to position, and even in the last stages of labor she might be allowed to do the same, except, perhaps, with reference to some general directions, and for these he would say the semirecumbent position in bed was the one best adapted to give her the greatest assistance.

The paper was discussed by Drs. J. C. Reeve, of Dayton, Ohio; Fordyce Barker, of New York; Theophilus Parvin, of Indianapolis; H. F. Campbell, of Augusta, Ga.; and A. Reeves Jackson, of Chicago, Ill.

The Society then adjourned to meet on Friday at 10 A.M.

Friday, Sept. 3d—Third Day—Morning Session.

The Society was called to order at 10.45 A.M. by the President.

The first paper was read by Dr. Theophilus Parvin, of Indianapolis, and entitled

SECONDARY PUERPERAL HEMORRHAGE.

This paper was complete, and "admirable equally for its literary excellence as for its scientific and practical value." The résumé of the literature upon the questions, what was to be understood by primary and what by secondary puerperal hemorrhage, was most exhaustive, and concluded with the author's definition of secondary hemorrhage, namely, that which occured at any time between six hours after labor and the end of the month, excluding certain mechanical causes, as inversion of the uterus, etc. The chief of the causes belonging to the uterus were included under two heads: 1, those which hindered uterine contraction, and 2, those which produced uterine congestion. When should woman rise from her bed after confinement, was a question which no law could answer, and the author favored the letting of the "nine days" be like the "nine muses," a fiction of the past. The causes of secondary puerperal hemorrhage were then enumerated, and then the author passed to the question of treatment, preventive and otherwise. It was in a properly conducted third stage of labor that many, if not most, secondary hemorrhages were to be prevented.

Hemorrhages occurring, what was to be done? The remedies recommended and the various plans of treatment were then reviewed in a brief but comprehensive manner.

The paper was discussed by Drs. Campbell, Wilson, Sutton, Barker, Shepard, and Englemann.

THREE FATAL CASES OF RUPTURE OF THE UTERUS, WITH LAPAROTOMY,

was the title of a paper then read by Dr. W. T. Howard, of Baltimore.

Rupture of the uterus with extrusion of the fœtus into the abdominal cavity was universally regarded as among the gravest accidents of parturition. Formerly they were regarded as almost uniformly fatal, but of late, since non-interference and violent and fruitless efforts to deliver through the contracted rent in the uterus had given place to laparotomy, highly encouraging results had been obtained.

Of the sixty cases, native and foreign, and collected by Dr. James Trask and Dr. Harris, recovery occurred in thirty-seven, and twenty-three terminated fatally after the operation.

Dr. Howard then reported three cases which illustrated and enforced some practical points of great interest and importance.

He purposely avoided discussing the plan of treatment to be pursued when the fœtus is *partially* in the uterine cavity, but when it has passed *completely* into the abdominal cavity, there were only three alternatives from which to choose.

1. To abandon the case to the efforts of nature—the chances of recovery being almost nothing.
2. To introduce the hand into the abdominal cavity, through the rent in the uterus, seize the child, and deliver; or,
3. Laparotomy, which by almost universal consent had taken the place of the second plan of procedure, because removal of the blood and other fluids was only second in importance to that of removing the fœtus itself from the abdominal cavity.

The paper was discussed by Drs. Wilson, Parvin, and Campbell, each of whom expressed the opinion that the suggestion made by Dr. Howard, and his proposed modification of Porro's operation, in certain cases, seemed to promise more for the woman than simple abdominal section.

Third Day—Afternoon Session.

The first paper was by Dr. Jas. R. Chadwick, of Boston, on

THE HOT RECTAL DOUCHE.

In selecting a title for this paper, the author intentionally rejected the term "enema," lest it should suggest that the practice of injecting hot water into the rectum had for its purpose the removal from that viscus of its fecal contents. He had, moreover, sought to ally the use of hot water in the rectum to the well-known hot vaginal douche, because their chief purposes and results were similar, though he believed the hot rectal douche to be in many cases most efficient.

The first group of cases in which he had of late been in the habit of relying upon the hot rectal douche as the sole therapeutic means, included cases having for their prominent symptoms *diarrhœa*, whether acute or chronic, characterized by small, frequent evacuations, the cause of which had seemed attributable to inflammation, or at least irritation of the mucous membrane lining the rectum and large intestine.

A number of avowedly typical cases of diarrhœa were then reported.

He came then to the second and far more important class of cases in which the hot rectal douche had proved eminently successful—*pelvic inflammations of all kinds.*

He then exhibited a diagram, taken from Savage, which showed with how restricted an extent of the peritoneum the vagina was in contact, and consequently how limited must be the effect of a vaginal douche in allaying peritoneal inflammation, and promoting the absorption of effusions. The rectum and large intestine, on the other hand, were seen to occupy the greater part of the pelvic and lower portion of the abdominal cavities.

The method of administration of the hot rectal douche, with a view to obtaining its utmost benefits, aimed at securing the passage of the water in large volume to as high a point as possible in the alimentary tract, and its retention for as long a period as possible. Water was taken at as high a temperature as could be borne by the hand; the patient was placed upon her side, preferably the right, in bed; a fountain syringe holding two quarts was employed, suspended quite low, so that the flow of water might be slow; as soon as the patient had a sensation of a desire to defecate, or the rectum was felt by the finger in the vagina to be distended, the current of water was arrested for a few minutes, without withdrawal of the nozzle from the anus. In that way one or two quarts of water might commonly be introduced without exciting peristaltic action. The patient must remain quiet for a quarter to half an hour, when, if not sooner, the rectum would generally have expelled a portion, if not all, of the water. He did not deem it wise for the patient to resist the expulsive action of the intestine, because it would thereby be incited to more violent efforts, which would counteract, in a measure, the beneficial action of the douche. He was unable to state how high in the intestine the water usually passed, but was satisfied that it occasionally traversed the whole large intestine to the ileo-cæcal valve.

The discussion that followed the reading of the paper was participated in by Drs. Howard, Campbell, and Reamy, who discussed at some length the question whether fluid thrown into the lower part of the large intestine went beyond the sigmoid flexure and beyond the ileo-cæcal valve. Dr. Reamy maintained that it did not go beyond the last point when injected *according to the method given in the paper*.

OCCLUSION OF THE GRAVID UTERUS.

The above was the title of a paper sent by **Dr. Joseph A. Eve**, of Augusta, Ga., and read by the Secretary.

Dr. T. A. Reamy, of Cincinnati, then read a paper on

ULCERATION OF THE CERVIX UTERI.

The following is a synopsis:

It was founded on an examination of eight thousand women supposed to be suffering from uterine disease. The author meant by the "ulcerative process" and by ulcer what was expressed by Paget and Billroth. Ulcerative processes, usually the result of detachment of dead portions or molecules of inflamed tissue. . . . Substance removed not absorbed but ejected. . . . An ulcer usually begins by slough or detachment of dead tissue by removing layers of living tissue that surround it (Paget). An ulcer is formed when, by the above processes, the vascular and proper tissue (submucosa) is removed (Paget). An ulcer is a wounded surface, which shows no tendency to heal (Billroth). Excluding syphilitic and cancerous ulceration, out of the total of eight thousand women examined there were found but nineteen cases of true ulceration. A large number suffered from abrasions, erosions—so called ulcers. The widely-extended disagreement between physicians as to the prevalence of ulceration, was attributable not to ignorance of a gross character, but to a difference of opinion as to where abrasion or erosion ceased and ulceration commenced.

The following papers were read by title:

"On the Diagnosis of Pregnancy in the Early Months." By Dr. J. T. Johnson, of Washington, D. C.

"Freund's Extirpation of the Cancerous Uterus." By Dr. J. R. Chadwick, of Boston.

"A Supplemented Contribution to the Pathology of the Cicatrices of Pregnancy." By Dr. S. C. Busey, of Washington, D. C.

"Manual Dilatation of the Os Uteri, as a means of Inducing Premature Labor." By Dr. W. L. Richardson, of Boston.

The hour for adjournment having arrived, the President, Dr. J. Marion Sims, congratulated the Society upon the marked success that had attended the present meeting, and then took leave of the chair in favor of **Dr. W. H. Byford**, of Chicago, the President elect.

Dr. Byford took the chair, and with an expression of thanks for the honor conferred upon him, and encouraging words for the future, accepted the Presidency of the Society.

He then declared the Society adjourned, to meet on the *third* Wednesday in September, 1881, in the city of New York.

The following are the officers elected for the ensuing year:

President.—Dr. W. H. Byford, of Chicago.

Vice-Presidents.—Dr. T. A. Reamy, of Cincinnati, and Dr. H. F. Campbell, of Augusta, Ga.

Council.—Drs. A. H. Smith, of Philadelphia; J. C. Reeve, of Dayton, O.; G. H. Lyman, of Boston; and J. T. Johnson, of Washington, D. C.

Secretary.—Dr. Jas. R. Chadwick, of Boston.

Treasurer.—Dr. Paul F. Mundé, of New York.

Dr. C. D. Palmer, of Cincinnati, was elected an Active Fellow, and Dr. D. H. Storer, of Boston, was promoted from active to honorary Fellowship.

◆

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, September 27, 1880.

Dr. A. E. M. Purdy, President, in the Chair.

FRACTURES OF THE TEMPORAL BONE.

Dr. Albert H. Buck read a paper having the above title, and the following is a brief abstract of it. Fracture of the temporal bone implied, almost necessarily, damage to some part of the middle ear or labyrinth, and, in consequence of that, many of the cases of fracture, after leaving the surgical wards of our hospitals, came into the aurist's hands for the relief of partial or total loss of the sense of hearing. The value of his picture of these cases, however, must depend upon the degree to which it supplemented those already drawn by surgical authors. By reason of its peculiar structure, fractures of the temporal bone were liable to take place in parts, and along certain fixed lines where the bone is weaker than at other points. From the study of the cases which had come under his observation, he found that he could make two grand subdivisions of fractures of the temporal bone.

First. Fracture or diastasis of the tympanic or squamous portion in the region of the middle ear, without implication of the petrous portion.

Second. Fracture of both the tympanic and the petrous portion.

In one or two of the fourteen cases observed, the symptoms seemed to justify a *third* subdivision, namely, fracture of the petrous portion of the temporal bone, without implication of the middle ear. The chain of evidence, however, though pointing strongly to such a conclusion, was not sufficiently complete to warrant the introduction of this third class. The first class, which included fracture of the temporal bone in the region of the middle ear, without implication of the petrous portion, might be broken up into smaller subdivisions. For example: 1, cases in which no visible hemorrhage or other discharge took place from the ear; 2, cases in which hemorrhage or bloody discharge from the ear *followed the accident;* and 3, cases in which the accident was followed by spitting of blood, due to its escape from the middle ear, by way of the Eustachian tube and into the naso-pharyngeal cavity or nasal passages.

The cases belonging to the second were, as a rule, of a more serious character than those belonging to the first grand subdivision. The severity and the duration of the illness which immediately followed the accident were usually so great, that the aurist never saw such cases until after the characteristic lesions in the region of the drum-membrane had disappeared. The line or lines of fracture might run in a variety of directions, and might involve other organs besides that of the ear proper, and from the symptoms produced we might also locate more or less accurately the course pursued by the fracture. To illustrate that point the histories of three cases were given. The complete loss of hearing power in those three cases constituted the distinguishing feature of this second class.

When in a case of injury of the head that symptom was discovered shortly after the occurrence of the accident, it was safe to assume, with the knowledge which we at present possessed, either that a fracture had taken place through the labyrinth, or that an extravasation of blood had taken place in the cochlea without fracture.

The next symptom to which Dr. Buck directed attention was that of bleeding from the ear. That symptom had always been considered of great diagnostic value. It was a prominent symptom in five of his cases. Reference was then made to Prescott Hewett's article "On Fractures of the Base of the Skull," in which stress was laid upon both the copiousness and the duration of the bleeding, and we were permitted to draw the inference that if the bleeding was not "of a serious nature" a fracture of the base might not have taken place. Dr. Buck thought that neither Hewett's observations nor his own warranted any positive statements on that point. Indeed, the whole subject of fractures of the temporal bone should be studied afresh. The author of the paper also maintained that in every case of suspected fracture of the temporal bone an aural examination should be made, and the conditions observed should form a part of the record of the case. Until that was done in a sufficiently large number of cases, it would not be possible either to confirm or refute authoritatively the statements made by Mr. Hewett. From his own experience he would say that the symptom of bleeding from the ear was susceptible of a somewhat broader interpretation than that given to it by Prescott Hewett, and he would add to Hewett's proposition, "*when a fall or blow upon the head is followed by bleeding from the ear, no matter how trivial, we may diagnose a fracture of the temporal bone in the neighborhood of Shrapnell's membrane, and probably in the line of the Glaserian fissure.*" By that proposition he meant to convey the idea, so far as the mere symptom of bleeding from the ears was concerned, that we were scarcely justified in assuming that the line of fracture extended beyond the region of the tympanum.

In the next place, the symptom of visible bleeding from the ears was not a necessary accompaniment of fracture of the temporal bone. On the other hand, evidence of inflammation of the part surrounding the drum-membrane afforded excellent evidence of such a fracture.

Of the remaining symptoms, the most important, after hemorrhage from the ear, was that of a watery discharge from the external auditory canal. Dr. Buck thought that the significance of that symptom has been very fairly stated by Prescott Hewett. In his own cases, there were but two in which the symptom of a watery discharge from the ear was well marked. In one it was probably partly inflammatory in origin.

In that connection he mentioned a fact with which every aural surgeon was familiar, and which should make us hesitate a long time before we pronounced a watery discharge, no matter how profuse, to be due to the escape of the cerebro-spinal fluid. The fact was that, in exceptional cases of acute inflammation of the middle ear, the flow of a thin, serous fluid from that cavity after the perforation had become established in the drum-membrane—whether by natural or by artificial means it mattered not—was so copious as to excite great astonishment.

Dr. Buck then examined some of his cases with reference to the source from which blood might possibly come, and with reference to the necessity of making thorough aural examination in every case.

Dr. Samuel Sexton, in opening the discussion, remarked that it had been his fortune to have lately seen two cases of fracture of the base of the skull, which had been kindly sent to him by medical friends, and both occurred as the result of falls from a wagon. In both there was slight unconsciousness from the shock. In both there was immediate trickling of blood from the ear—not great in quantity however. The patients were confined to the house—one for one month, the other for two or three weeks. One suffered from pain and deafness; the other had no deafness; but accumulations of inspissated blood in the meatus occasioned great distress to both of the patients and caused them to suffer more than from any other part of the injury. He had seen no allusion to this complication in the literature of this subject, and he believed it had not been mentioned by the author of the paper: in one of his cases the irritation of this hardened blood gave rise to a painful crop of furuncles. In both cases there was *tinnitus aurium*, which seemed to indicate that the middle ear had been somewhat affected. Both patients complained of headache for a long time, and in both vertigo was a prominent symptom, and still continued. These patients, since the injury, were very nervous, easily tired, and forgetful. As regarded symptoms of fracture of the base of the skull in those cases, there was extravasation of blood under the eyes of one and behind the mastoid of the other. The mastoid extravasation disappeared in a few days; the extravasation in the other case lasted longer, and there was expectoration of blood for a long time, and apparently coming from the pharynx. The seat of the fracture in these cases, Dr. Sexton said, was difficult to locate.

As to the point in diagnosis where there had been a large serous discharge from the ear: in one of his cases the patient informed him that there had been a copious watery discharge from the ear; it was subsequently found to be incorrect, however, and it occurred to Dr. Sexton that by making use of the tuning-fork he might be able to ascertain whether or not there had been fracture of the petrous portion of the temporal bone, an injury likely to wound the auditory nerve; but he found that the hearing was better upon the injured than upon the other side.

Dr. E. Eliot read an obituary notice of the late Dr. Chas. M. Allin.

Nominations for officers for the ensuing year were made. Several amendments to the by-laws were proposed, to make them harmonize with the provisions of the new law regulating the practice of physic and surgery.

The Society then adjourned.

Correspondence.

"ON THE RELATION OF MUSCLE AND NERVE."

[To the Editor of The Medical Record.]

Sir:—While not seeking to enter on a controversy with you in regard to your recent editorial criticism of my theory, I trust, in justice to it and to me, that you will kindly permit the following remarks to appear.

In presenting certain facts, "pretty definitely known" as the basis of an argument against my theory, you state: "In the first place, it is known that a muscle can contract, when irritation is directly applied, *without the intervention of nerves*" (italics mine).

This proposition has been generally accepted, but it has never been proven, and the inter-relations of nerve and muscle are such that to prove it is impossible. I need not remind you, on Dr. Klein's authority, that every part of a muscle is impenetrated by nervous tissue, even to the nucleolus of the nuclei of the muscle-cells. This being the case, it is impossible to operate on any portion of a muscle without at the same time implicating a corresponding series of ramifications of nervous tissue. Those experiments, therefore, which purport to deal with muscular tissue alone, to the exclusion of nerve-tissue, are erroneous, and the conclusions sought to be deduced from them are not entitled to acceptance as established facts.

This is not the place to enter on an *exposé* of the fallacies of the experiments relating to muscular contraction; but let us glance for a moment at the conditions advised as best adapted for the production of "ideo-muscular contraction." Dr. Michael Foster recommends for this purpose the selection of "a nerve-muscle preparation, which has been *much exhausted* by treatment, or by *long removal* from the body" ("Hand-book Phys. Lab.," p. 396) (italics mine). Why is this? If the blow with which we are to "strike the muscle sharply" acts as a stimulant, would not a fresh and vigorously acting muscle be more easily roused to action than one "much exhausted"? On the other hand, if muscular contraction be due to the absence of nervous action, as Dr. Radcliffe claims to have proved, an exhausted nerve is precisely the one best fitted for the purpose, since it is more readily and more certainly completely paralyzed by the assault made on it than would be the case with a recent or unexhausted nerve. That it is through the nerve, rather than by direct impact upon the muscle itself, the ordinary wave of contraction is produced, is shown by the well-known fact that a blow, pinch, burn, etc., applied to the nerve-trunk alone, extraneous to the muscle, produces the desired effect equally with a similar application to the combined nerve and muscle.

It has been *assumed* that the blow, pinch, burn, etc., acts as a stimulus; but the experiments do not prove this. They prove that muscular contraction attends certain actions done to the nerve alone, and to the combined nerve and muscle, but *how* this result is brought about is merely a matter of inference, and yet by the medical scientists of the day this *inference* is promulgated as a fact established which must pass unchallenged despite authenticated facts which weigh against it. You do not attempt to refute these facts, but content yourself with a reiteration of conclusions which are unproven, and which the experiments relied on for their support do not warrant. In the words of a vigorous Old World writer (Dr. Inman), until we rely "upon logical deductions rather than on what are called 'time-honored facts,' because they have been asserted for a century or two—though not facts at all—the practice of our profession will not improve."

As for the objection regarding the absence of muscular contraction during the operation of a nervous paralyzer like curare, I admit that if it were *proved* that curare paralyzes the *terminal motor nerves*, the objection would be a serious one. As this has not been proved, and the allegation is a mere inference, deriving all its force from its relation to the theory now prevalent; as, besides, the allegation may at any moment be disproved by additional evidence, the objection may be passed over. All the phenomena of curare-poisoning admit of explanation by its paralyzing action on the larger nerve-trunks, leaving the terminal nerve-ramifications free to control the muscles.

In drawing a distinction between tetanized and normally contracted muscles, you state: "Dr. Austin Flint, jr., believes that urea is produced by and is the measure of muscular action. Urea, however, is not found in tetanized muscle." This is not a fortunate argument. Recent facts, of careful experimentation, by able observers, who have "solved this problem in a remarkable manner," establish that muscle in action consumes not nitrogenous elements but the hydrocarbons principally, and that "muscular labor causes scarcely any increase in the excretion of urea." (See the facts fully stated in Prof. Küss's lectures, etc. (Duval, Amory), pp. 78–9.) This renders your argument unnecessary; and as to the other considerations regarding rigor mortis, they need not be referred to until the physiological facts elsewhere adduced in the Record are met and refuted.

I do not intend to discuss in this place the alleged electrical phenomenon of nerve and muscle, on which Professor Trowbridge's conclusive experiments have thrown the gravest doubt. But even were these currents certainly shown to exist, may they not originate in the molecular changes attending the *release* as well as the stimulation of muscle? If, as Professor Draper states, a "close analogy between nerve and muscle" is to be inferred, because cells enter into the structure of both, then the same doctrine will apply to every organ of the body, which, as a basis from which to infer a similarity of function, is absurd. It would be strange, indeed, if two structures so entirely different in composition, in form, and in their relation to other parts of the organism, as nerve and muscle, should evolve forces so much alike as to have a similarity of office.

You unintentionally do me an injustice in regarding my theory as an extension of, or in any way associated with, the "inhibitory" hypothesis of the day. So far from this being the case, I claim it as a special merit of the theory I advocate, that it renders this supposititious array of "inhibitory" nerves and their hypothetical "centres" and other "apparatuses" quite unnecessary to a full explanation of the facts and phenomena of the organism in health and disease. It is therefore too bad that, while really seeking to dispense with the incubus of "inhibition," you characterize my views as "inhibition run mad."

With these brief remarks, I leave the question at issue to your readers, trusting your kindly sense of justice and fair play will permit them to appear, well knowing that a subject of this kind, presented as it has been, can hardly escape being sometimes misapprehended.—Yours respectfully,

THOMAS W. POOLE, M.D.

LINDSAY, ONT., September 27, 1880.

[We publish with pleasure Dr. Poole's courteous letter. We have but little comment to make upon it, as he brings nothing new to strengthen his hypothesis, and it is on hypothesis which we affirm again to be unproven and undemonstrable.

In regard to the fact of idio-muscular contractility, there are few of the difficult points in physiology that are more clearly settled. We refer Dr. Poole to the investigations of Schiff, Kühne, and Heremann; also to the recent experiments of B. F. Lautenbach, and to the facts of comparative physiology. There are contractile organisms without nerves.

The theory of Dr. Poole, as we understand it, is that the nerve holds on to the muscle until a paralyzing wave is sent down, when the nerve lets go and the muscle contracts. In a state of rest the nerve is constantly exercising a repressive inhibitory action. We therefore spoke of the theory as an inhibitory one, and must still consider it so. If Dr. Poole really means that the nervous system exercises no active influence during muscular repose, and that a nervous impulse passing to the muscle liberates its activities, transforming potential into kinetic energy, he has not made his meaning clear. And if he did mean this, he has been arguing all along for theories already adopted.—ED.]

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from October 3, 1880, *to October* 9, 1880.

HAPPERSETT, J. C. G., Major and Surgeon. Assigned to duty as Post Surgeon at Fort Brown, Texas, to enable Asst. Surgeon F. Meacham to comply with S. O. 190, C. S., A. G. O. in his case. S. O. 19, Department of Texas, September 29, 1880.

BREWER, J. W., Capt. and Asst. Surgeon. Assigned to duty at McPherson Barracks, Atlanta, Ga. S. O. 117, Department of the South, October 7, 1880.

DICKSON, J. M., Capt. and Asst. Surgeon. Assigned to duty as Post Surgeon at Vancouver Barracks, W. T. S. O. 171, Department of the Columbia, September 24, 1880.

HEIZMANN, CHARLES L., Capt. and Asst. Surgeon. Granted leave of absence for one month, with permission to apply at division headquarters for an extension of one month, and to the Adjutant General of the Army for a further extension of two months. S. O. 170, Department of the Columbia, September 23, 1880. Leave of absence extended one month. S. O. 143, Division of the Pacific and Department of California, September 28, 1880.

CRONKHITE, H., Capt. and Asst. Surgeon. Assigned to duty as Post Surgeon at Camp Sheridan, Nebraska. S. O. 94, Department of the Platte, October 5, 1880.

WEISEL, D., Capt. and Asst. Surgeon. Assigned to duty as Post Surgeon at Fort Warren, Mass. S. O. 181, Department of the East, October 8, 1880.

GRAY, WM. W., First Lieut. and Asst. Surgeon. When relieved by Asst Surgeon Dickson, to report to commanding officer, Fort Canby, W. T., for duty as Post Surgeon. S. O. 171, C. S., Department of the Columbia.

GORGAS, W. C., First Lieut. and Asst. Surgeon. Assigned to duty as Post Surgeon at Fort McIntosh, Texas, to enable Asst. Surgeon J. H. T. King to comply with S. O. 190, C. S., A. G. O., in his case. S. O. 199, C. S., Department of Texas.

Medical Items and News.

CONTAGIOUS DISEASES — WEEKLY STATEMENT. — Comparative statement of cases of contagious diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending October 9, 1880.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro spinal Meningitis.	Measles.	Diphtheria.	Small-pox.	Yellow Fever.
Oct. 2, 1880.	0	14	50	3	6	91	0	0
Oct. 9, 1880.	0	16	58	2	11	97	0	0

DR. J. H. MACDONALD, Ex-president of the Canada Medical Society, and member of the Medical Council of Ontario, has been on a brief visit to this city. During his stay he was the recipient of the hospitalities of many prominent medical gentlemen here. On Oct. 11th he held an informal reception at the house of his friend, Dr. D. W. Goodwillie of this city.

REQUIREMENTS FOR PRACTICE OF MEDICINE IN NORWAY.—We take the following from Hardwicke's recently issued "Medical Education and Practice in all Parts of the World:" "To matriculate as a student of medicine, the applicant has to pass two preliminary examinations: one in arts, including Norwegian, Latin, Greek, French, German, English, mathematics, geography, and history; and one in philosophy, including geometry, zoölogy, botany, astronomy, and the elements of chemistry and physics. He then enters on the study of medicine proper, which occupies nearly seven years. There are three professional examinations, arranged as follows:

"First examination, held two years and a half after matriculation, upon anatomy, dissections, use of the microscope, histology, chemistry (organic and inorganic), zoölogy, and botany.

"Second examination, held three years and a half after the first, upon physics, pharmacology, toxicology, medicine, therapeutics, general pathology, and pathological anatomy, ophthalmology, skin diseases, and surgery.

"Third examination, held about a year after the second, upon surgery and bandaging, topographical anatomy, obstetrics and gynæcology, diseases of children, forensic medicine, hygiene, and a practical examination in medicine and surgery. Thorough practical work in connection with the various hospital wards is also obligatory. Upon passing the final examination the candidate becomes a physician, and receives the right to practise. If he further desires to receive the degree of Doctor of Medicine, there are additional examinations and requirements."

DR. EBEN HUNT, Junior Assistant First Medical Division, Bellevue Hospital, died at 20 West Twenty-fifth Street, New York, on September 3, 1880, of diphtheria.

Dr. Hunt was born in Gilford, N. H., November 2, 1845. He was graduated from Gilford Academy, in Gilford, N. H., in 1866, and from Dartmouth College, at Hanover, N. H., in 1870; was Professor of Ancient Languages in Hooper's Academy, in Yonkers, N. Y., from 1870 to 1873; Professor of Chemistry and Natural and Experimental Philosophy in the Chester Military Academy of Pennsylvania, at Chester, from 1873 to 1877; and Instructor in Greek in the University of the City of New York, from 1877 to 1879.

He was graduated from the Medical Department of the University of New York in 1879, and was then appointed on the medical staff of Bellevue Hospital, where he was serving at the time of his last illness.

At a meeting of the staff of Bellevue Hospital, the undersigned were appointed a committee to express to Dr. Hunt's family their sympathy in the loss sustained by his death, and to insert the above sketch of his life in THE MEDICAL RECORD.

A. CRESSAP MCCOY, M. D.,
WILLIAM S. CHEESMANN, M.D.,
REESE H. VOORHEES, M.D.,
THOMAS D. SWIFT, M.D.

BELLEVUE HOSPITAL, September 30, 1880.

THE DEATH OF DR. CHARLES M. ALLIN, OF NEW YORK.—At a stated meeting of the Medical Society of the County of New York, held on the evening of September 27, 1880, the following report was accepted, and the resolutions contained unanimously adopted:

The committee appointed to prepare a suitable minute in regard to the death of Dr. Allin respectfully submit the following:

Charles Mason Allin, A.M., M.D., who was born at Providence, R. I., October 30, 1827, died in this city, after a prolonged illness, June 20, 1880.

Your committee recommend that it be

Resolved, That in his death this Society, and the medical profession as well, have lost one who, though but just in the maturity of manhood, had gained an enviable position in his chosen calling.

Resolved, That in his life we recognized an example of great industry, unsullied integrity, excellent scholarship, and unusual public spirit, which made his career of great service to his fellow-men, and his death deeply regretted by all with whom he has been associated.

Resolved, That we respectfully offer to his family our heartfelt sympathy in the affliction which has deprived them so prematurely of an exemplary husband and father.

Resolved, That a copy of this minute, signed by the President and Secretary, be sent to the family of Dr. Allin, and to THE MEDICAL RECORD for publication.

ELLSWORTH ELIOT.
A. B. BALL.
A. E. M. PURDY, President.
F. A. CASTLE, Secretary.

SEPTEMBER 27, 1880.

THE HYDROPHOBIA IN FRANCE.—The number of cases of hydrophobia, for the Department of the Seine, that have occurred in dogs during the present year, is 127. Of these 103 were bitten by other dogs. There were twenty-four persons who had been bitten by mad dogs, but of these only two had developed hydrophobia.

EFFECTS OF MEDICAL LEGISLATION IN ILLINOIS.—The Philadelphia *Medical and Surgical Reporter* presents the following facts regarding the effect of medical legislation in Illinois: In July, 1877, when the law first went into effect, there were 7,400 physicians in the state, of whom only 3,600 were licensed or qualified practitioners. In 1880 the number of qualified practitioners had increased to 4,825, while the unqualified practitioners had decreased to 1,500. The total number has thus decreased to 6,325. The number of itinerants has decreased from 73 to 9, and the number of cancer doctors from 23 to 4.

SICK CHILDREN'S EXCURSIONS IN EUROPE are becoming more extensively undertaken every year. Starting at Zurich, at the instigation of Pastor Bion, the practice of sending out companies of sick children into the country during the summer has extended to the cities of Frankfort, Dresden, Stuttgart, Vienna, and Berlin.

HAPPY MEMPHIS.—During the last week of September the city of Memphis celebrated its freedom from pestilence the past summer. The city was decorated with flags; there were fireworks, illuminations, processions, and crowds of visitors. Memphis may well be glad. It was a critical time for her. If the yellow fever had appeared a third time the city would have been ruined.

THE INTERNATIONAL CONGRESS OF HYGIENE held a meeting at Turin, September 7th to 11th last, Prof. Panchiotti presiding. Representatives from Germany, France, Switzerland, Bucharest, and Italy were present, and took part in the discussion.

The first subject considered was that of inter-ternational quarantine. The creation of an international sanitary council was recommended, but no further definite steps taken.

The congress recommended the establishment of health boards in all the states and countries. It endorsed compulsory vaccination, recommended the teaching of science in the universities, heard an essay on the eucalyptus, saw a body burned up at the city crematory, and adjourned to meet at Geneva in 1882. Nothing appears to have been said about the sanitary conference proposed to be held in this country next year.

THE PHILADELPHIA CORONERSHIP.—It is rumored that Prof. Henry Leffmann, well known as a chemical expert and as a teacher of toxicology, will be a candidate for coroner of Philadelphia. The office is one requiring medico-legal training, and it is therefore evident that a medical man of ability and acceptable to the profession would make a strong candidate.

THE NEW SYDENHAM SOCIETY during the coming year is to have translated a selection from Duchenne's works; also Charcot's Lectures on the Diseases of Old Age, and on Certain Chronic Maladies.

NIGHT MEDICAL SERVICE.—At a stated meeting of the New York Academy of Medicine, held at the Academy's Hall, 12 West Thirty-first Street, October 7, 1880, the following preamble and resolutions were offered by Prof. A. C. Post, and were unanimously adopted:

It being one of the objects of this Academy to approve and further any innovation tending to advance the science and art of medicine, or to facilitate the beneficent practice thereof; and, moreover, it being our desire to show due appreciation to those who may, by their labors, have succeeded in accomplishing such an end, therefore be it

Resolved, I. That this Academy believes that the establishment of the Night Medical Service in the city of New York is a boon to the community; and that by its means much good will accrue to both patients and physicians, inasmuch as it places by the side of the suffering patient skilled medical attendance at the shortest notice; and on the other hand, gives the assurance to the physician that his merited remuneration will be duly received.

II. Believing the law to be a benefit, and recognizing the fact that it is due to the earnest and well-directed efforts of Dr. Henri Nachtel, a stranger among us, that we owe its establishment, we therefore desire to testify to him our appreciation, and to extend our cordial thanks for his disinterested zeal in accomplishing so much good for the welfare of the community, including the medical profession.

III. *Resolved*, That the above resolutions, signed by the President and Secretary, be engrossed and forwarded to Dr. Nachtel in Paris.

Edwin F. Ward, M.D.,
Recording Secretary.

Erythroxylon Coca in the Opium and Alcohol Habits.—Dr. W. H. Bentley reports in the *Therapeutic Gazette* eleven cases of the opium-habit, all but one of which were cured by the use of a pound or two of erythroxylon coca. Three cases of inebriety were also said to be cured. The drug is given in drachm doses of the fluid extract, increased if necessary and repeated till some relief from the morbid desire is felt.

Canada Medical Association.—The thirteenth annual meeting of this association was held Sept. 1st and 2d, at Ottawa, about 100 members being present. Drs. Brodie, Brush, and Goodwillie, delegates from the American Medical Association were present and were elected honorary members. The work of the society was done in a general session and two sections, one on medicine, the other on surgery. Thirteen papers were read, several of them exciting quite lengthy discussion. Venesection received considerable favor. The dangers of "cramming" children and the evils of the present system of education were discussed. Dr. J. A. Sewell reported cases in which tea had acted efficiently as an antidote in opium-poisoning. Dr. Stewart reported fifteen cases showing the efficacy of cannabis Indica in the treatment of hemicrania.

In the surgical section the treatment of wounds was the subject of discussion. No defenders of Listerism appeared. There were papers upon the subject of Brain Lesions, Plastic Operations on the Eyelids, Mastoid Disease.

The Presidential address by Dr. Howard was devoted to urging the importance of health legislation. He also spoke of the needs to society of state inebriate asylums, and he recommended that there be medical experts at coroner's inquests.

The address was spoken of as a very able one. The meeting itself was also considered a success.

The next annual meeting will be at Halifax, N. S., Aug. 3, 1881.

The Dengue or Break-bone Fever at Charleston.—An account of the epidemic of break-bone fever at Charleston has been furnished to the Bulletin of the *National Board of Health*, by Dr. F. P. Porcher. We give this in substance below: Charleston has always been peculiarly subject to this fever, and at times it has affected seven-tenths of its population. The present epidemic is not a very severe one and is now abating. The Charleston Board of Health has expressed considerable indignation against the National Board for publishing the facts concerning the outbreak. It is thought that the commercial interests of the city will suffer in consequence:

Dr. Porcher says of the symptoms:

The disease generally begins with a feeling of coldness, or by a chill, followed by fever. This, with a temperature ranging from 100 to 105°, lasts generally from 24 to 48 hours, occasionally extending to four or five days, and even in rare cases to seven. Relapses occasional, specially in those who have gone out too early. Headache frequent, generally frontal, from the beginning. Miliary eruptions, sometimes elevated and red, like measles, and the occasional presence of *sudamina over the face, neck, and body;* sometimes the eruptions were confined to the body, and endured for days after recovery. We have seen some examples of slight desquamation—furfuratious or branny in character. Sweating profuse in many persons, though *often absent.* Hence, some physicians are inclined to consider the disease to be *suette miliare* of a mild form. "Breakbone" is the best name, because pain in the bones and limbs is the most constant symptom. There is often great restlessness during the fever, and in some a feeling of tightness or congestion about the throat, with bleeding in a few cases known to us. Catarrhal symptoms are rarely present, although cough has occasionally existed. Bleeding from the nose not unusual in children, and also increase in the menstrual molimen has been observed. Pain in the back and limbs markedly present, but no decided swelling of joints, no carbuncular enlargements or boils, as in the epidemic of dengue of 40 years since, or in that of "breakbone," which followed some years subsequently. Weakness and prostration have been very decided, but not nearly to such an extent as in previous epidemics. Some of the physicians consider that there has been a tendency to hepatic torpor or congestion, of no great severity, however. We have heard of no cases of decided jaundice. Nausea and vomiting seldom occur.

The disease does not affect all the members of a household, oftentimes only one or two being seized, though we have known six to be taken in one house; in this respect differing from the dengue, as described by Prof. Dickinson, and from the epidemic seen by us some thirty years since. Then 10,000 were down; no one was well enough or strong enough to help his neighbor, and one had to learn to walk over again.

It is difficult to calculate the number who have suffered, as very many have not employed a physician; from 2,000 to 3,000, perhaps, approximates the number.

Very little active treatment has been used; as far as we can learn, as follows: A mild laxative, saline or mercurial, hot teas, nitre, pediluvia, sinapisms, etc., and quinine during and after the attack, upon theoretical grounds, with occasionally mild stimulants. Several persons have recovered with no treatment whatever.

It has prevailed among both races, perhaps equally, and *not a single death is ascribed to this disease* as far as we can learn. The only disadvantage which accrues to those who take it is the time lost and the temporary pain and weakness from which they suffer.

Original Lectures.

EXCISION OF THE INFERIOR DENTAL NERVE,

By Means of the Dental Engine, for the Relief of Obstinate Neuralgia.

A CLINICAL LECTURE.

By JAMES E. GARRETSON, M.D.,

PROFESSOR OF ANATOMY AND SURGERY IN THE PHILADELPHIA DENTAL COLLEGE.

The case before the class is one of neuralgia of the region supplied with sensation by the third division of the fifth nerve. The woman is so great a sufferer that, as life itself is concerned, there exists absolute necessity to afford her relief. To accept her own story, the pain aroused in the simple act of opening the mouth is so great that she has starved during the last nine weeks rather than endure it.

What is neuralgia? It is nothing, it is everything. The term itself signifies pain, nerve-pain; that alone. To say that a person has neuralgia is to express nothing in the way of cause; an aching toe is a neuralgic toe; so, too, an aching tooth; so, also, a paining heart.

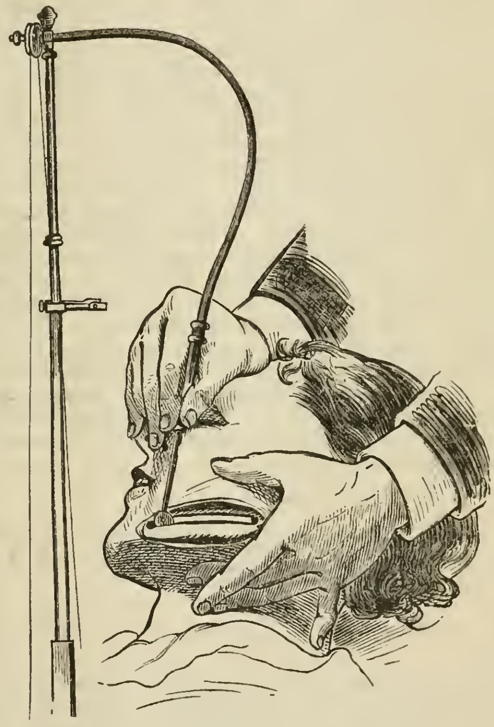
In a case of neuralgia, that which the surgeon wants to get at is *cause*. To diagnose simply that a patient has neuralgia is to say nothing more expressive of the doctorly attributes than is spoken by a child when complaining of a stomach-ache. Without an added explanation as to cause, he who diagnoses neuralgia diagnoses nothing. Pain arises out of irritation, and diagnosis in neuralgia is appreciation of the thing that irritates.

In this hospital, where are treated so many cases of neuralgia, large opportunity is furnished for the study of cause. So much in the way of cause are we constantly exposing, so much in this way have we discovered, that naturally Anstie's views come to stand in little favor with us. Only a single week back, as you remember, I told the class about a private patient, just dismissed at the time, where the pharmacy had been exhausted in the constitutional treatment of a tic douloureux, found finally to be dependent on an ulcer situated upon the inner face of the uterine fundus. In proportion as the ulcer responded to the treatment employed for its cure, so did the pain disappear. A multitude of similar instances are familiar to this clinic.

The patient before us has neuralgia from a cause. From what cause? From the presence of an irritant. Where is the irritant, and what is it?

In the press of the service to-day I have no time to tell you how I arrived at a conclusion that the trouble is disorganization of a nerve, and that the part affected lies in the dental canal of the lower jaw. A matter of interest to the class, and as well of vital concern to the patient, is the correctness of the inference made.

I now proceed to expose and resect the inferior maxillary nerve. Here, gentlemen, I introduce you to a manner of performing the operation which I am sure needs only to be seen to be appreciated. The operation is one of my own devising. I show you the lady without a scar; I desire to cure her without making one. Now to the surgical indications of the case. The first is to operate without resulting disfigurement; the second, to so expose the nerve that it may be examined before being lifted; the next is the cutting of the bone in such manner as will justify me in acting from the conclusion of no suppuration. The patient will now be etherized. . . . I now pull the skin of the neck upward upon the jaw, and thus draw up the shade-line from the base of the face (right side) until it rests upon the body of the inferior maxilla; and then, feeling for the facial artery, I protect it by my finger-nail placed just in front. Inserting the blade at this point, with its heel toward my finger, I cut forward, making an incision about an inch and a half in length parallel with the bone. Now my assistants, with the aid of retractors, pull the artery backward and also stretch and hold the lips of the wound apart. No hurry, gentlemen; make haste slowly. I now remove a strip of the periosteum corresponding with what I judge to be the breadth of the maxillary or inferior dental canal. This is accomplished with the aid of the raspatory at the end of the scalpel. I look now for the mental foramen, which I know signifies the position of the canal. I have it.



Now I resort to the *engine*, with a fine circular saw attached making at least two thousand revolutions a minute. The machine, as a whole, is noiseless and efficient in operation. Rapidly as this little saw is revolving, I hold the hand-piece and can control it as I would a pen. The delicacy of its manipulation in experienced hands every surgeon who has ever used it must appreciate. I pass the saw from the mental foramen backward along the margin of the canal. The upper side is cut. Back again to the starting-point, and soon the lower portion is divided. Now, replacing the saw with this delicate trephine, I sever the strip of bone at either extremity, and with this finely tempered chisel pry up and remove it. Underneath should lie (normally) the vessels and the nerve, but here I have from pathological expressions diagnosed an abnormal condition and disorganization of the nerve ; or it may be that an inflammatory exudate is pressing upon it, or, possibly, a foreign growth developing within the canal. I will examine. See with what ease we proceed—no anxiety, no blunder, but perfectly satisfy ourselves as to what we have or have not. I do not find anything like a nerve in the centre of this canal. Gone. disorganized as well as the vessels ; I was right in my diagnosis. Now, I have the end of the posterior portion of the nerve. Before exsecting it at the posterior part of the opening I will stretch it, in order to obtain whatever benefit may result from such stretching. I now divide it. The end of the anterior portion is as red as a cherry. I will cut it out also.

Now I wash and cleanse the parts, which is an important point to be observed. Again the engine. This time it carries an inverted conoidal corundum disk, with which I smooth down the roughness and points around the margins of the opening, for I do not wish to have necrosis or caries, which there might not be sufficient vitality to resist. I am careful to have no foreign material enclosed. *That* would interfere with my calculations. Finally, I bring the lips of the wound together in such manner as to leave no *bag* to give trouble. I aim to get as immediate union as possible. I have not used a single ligature. If hemorrhage *should* occur, the wound can be opened and the bleeding arrested by packing. My dressing is antiseptic and dry. Now, gentlemen, there is a nerve resected and no deformity. The indications have all been met, and I expect you to appreciate the refinement of the operation æsthetically.

(The patient was kept in the ward for two or three days and then sent home. Two weeks afterward her physician sent word that she was relieved of pain and doing exceedingly well.)

A CLINICAL LECTURE.

By C. R. AGNEW, M.D.,

NEW YORK.

Case I.—*Facial Erysipelas—Treatment of Lachrymal Abscess.*

This man comes with an extensive patch of redness upon the left side of his face, covering the eyelids of the left eye, extending over the bridge of the nose, down upon the cheek to the angle of the mouth, and back half way to the angle of the jaw. Upon the bridge of the nose it is broken by what seems to be a ruptured bleb, and scattered about that broken bleb are two or three vesicles, little blister-patches of skin, looking as though beneath them were some serous fluid. Now, it is a question whether this is an eye case or whether it belongs to some other surgical category. The patient is twenty-five years old, and a shopkeeper by occupation. He says that last Saturday he felt chilly, went home, went to bed. Upon Sunday was up about the house ; went to bed about ten o'clock in the evening ; felt chilly at that time, and his eyes began to hurt him, were red, and water ran out of them, and on the following morning the eyes were swollen, the face on the left side was broken out, and this morning the left eye was closed entirely. He also says that he takes "a drink occasionally," and that the left eye was hurt about a year ago by being partially *gouged* out. This is an operation the results of which, several years ago, we used to see a great deal of. The operator who felt inclined to perform it twisted the forefinger into a lock of the hair of the objective, and then inserting the thumb of the same hand into the temporal or nasal side of the orbit, pressed the eyeball out upon the side of the cheek. This practice, however, I am glad to be able to say, seems to be going out of use, with some other practices which seem to be flagging.

The pupil of that left eye is a little larger than the pupil in the fellow eye, and he says he has not been using any drops in the eye. His eye looks as though he had paresis of the sphincter of the pupil, either from some morbid condition of the nervous supply, or from the effect produced by some mydriatic. It is barely possible that the slight dilatation of the pupil in this case may be due to the injury to which he has alluded. We have, then, this red patch and swollen eyelids, and when a man presents this condition you must look carefully to the tear apparatus, because I have seen just such a blush springing from inflammation of the lachrymal sac ; not sufficient to produce abscess of the sac nor obvious swelling of the sac, because this inflammation at the side of the nose and upon the cheek produces more or less œdema of the connective tissue, which elevates the skin and submerges the small swelling existing in the sac itself. The condition of the lachrymal sac, therefore, must be carefully ascertained, and that can be done by placing the finger or thumb by the side of the nose, over the region of the sac, and making gentle pressure. If you find a doughy swelling in the region of the tear-sac, and by pressure can squeeze out from one of the puncta a semi-glairy, muco-purulent fluid, you may feel confirmed in the belief that there is some tear-sac trouble. But in this man's case I cannot see, at this moment, that there exists any such trouble. The nostril upon that side discharges rather more freely than the other. A sharp catarrhal inflammation of the mucous membrane of that tear-sac and nasal duct might, by contiguity, develop inflammation of the skin. Then, again, it might be a patch of erysipelas, and to that view color is lent by the fact that when it began he was chilly all day, went to bed feeling chilly, etc., and prodromal symptoms continued for several hours just before the red patch appeared. He seems to have had that kind of malaise characteristic of the onset of an attack of erysipelas, this cutaneous outbreak being merely an external expression of that peculiar vitiation of the blood which exists in connection with erysipelas.

It is decidedly erythematous or erysipelatous-like ; it is limited rather sharply about the edge ; pressure upon it causes the blood to desert the capillaries, but it quickly returns, and I should be disposed to think that it is a patch of erysipelas following some catarrhal inflammation about the nostrils, with a little catarrhal inflammation of the conjunctiva of the lids occurring in a man whose general condition is not good. His tongue is furred, and his hand is rather shaky. He uses tobacco to excess.

[Here the patient went into the adjoining room.]

You cannot always depend upon everything which a patient says. I did not wish to expose him before the clinic regarding the matter of habits ; but he does not look as though they were altogether hygienic, and yet I should be sorry to have any prejudices against him. He looks to me, however, "a little stale," to employ an expression used among trainers, as though he was in that condition in which the laws of waste and repair are so disturbed that he is not quite right relative to his tissue-metamorphosis. There is a lack of clearness about his complexion which we should not see in a man at his time in life. The fact, also, that he suffered from the peculiar injury of his left eye at one time is rather suggestive.

Nothing new was learned in the private examination.

As to treatment, I should give him some mild laxative—say, a wineglass of bitter water in the morning, in a tumbler of hot water, a mild saline laxative which will clear his mucous membrane; and then a little quinine—say, two grains t.i.d., and put upon that reddened surface some simple wash. As there is no eye-affection, I should use a solution of acetate of lead, ʒj. to Oj. of water, and he should keep out of the wind, should not be exposed to wet or cold, and should have a diet consisting chiefly of milk, with a moderate quantity of meat once a day.

Although there is no swelling about the lachrymal sac, I think it is worth while to watch it, because it is quite possible that the lining of the sac is in a state of catarrhal inflammation just sufficient to give rise to the cutaneous inflammation, and that we may yet see the sac fill up. The fact that the nostril upon that side is wet seems to show that the catarrhal difficulty gets vent into the nostril—that there is no stricture. Yet it is worth while to watch the sac itself.

Now, suppose that to-morrow we should find a distinct swelling in the region of the left lachrymal sac—a doughy, somewhat egg-shaped swelling extending up along and behind Horner's tendon—and upon pressure we should be able to cause to exude a little glairy fluid from one or both puncta, but not sufficient to empty the tumor—and no reasonable amount of pressure will be sufficient to press its contents down into the nose; suppose you make up your mind that you have to deal with a beginning abscess of the lachrymal sac, are you prepared to mark out a line of treatment?

One of the gentlemen answers, "I would slit up one of the canaliculi." That is correct; that is the rule, and it should be given with emphasis. It is not more than two or three weeks ago that I saw such a case, in which a good surgeon had made an external opening. Now, what is the objection to such an operation? The answer is a two-fold one: first, it will leave a scar, and the risk is taken of having a lachrymal fistula follow the incision. So you would no more think of making an external opening into the sac, than you would of opening into the bladder through the perineum, to let the urine out of a distended bladder, before trying to evacuate it through the urethra. The first attempt should be in the direction of emptying the bladder by way of the natural passage. Now, if an accumulation of material occurs in the lachrymal sac of this man's eye, and it cannot be relieved through the nasal duct or through the canaliculi, then you must cut into the sac by entering the natural opening, and, if needs be, enlarging that opening to enable you to effect a free entrance. You would then apply the well-established rules of surgery in the treatment of such cases, and slit up either the lower or upper canaliculus. I think it is better to open the lower one, because it is more easily reached. Then, having slit up the canaliculus, you should try to evacuate the contents of the sac through the opening made by your instrument.

But suppose the swelling of the skin and the subcutaneous connective tissue is so great over this distended lachrymal sac that you cannot get at the lower punctum, what should be your procedure then? I have seen such cases frequently. You wish to empty the abscess at the earliest possible moment, and how and where should the incision be made? One gentleman answers that he thinks we would be obliged to cut through the integument. The anatomy of the parts is about as follows: we have first the eyelids covering the eyeballs, and toward their inner extremities we have the puncta. Now, behind this angle, which is called the internal canthus, you have that little gland called the caruncle, and now, just in the crease between the caruncle and the angle of the eyelids there is nothing between the external world and the cavity of the sac but conjunctiva and the sac-wall. As the sac fills up with matter, its anterior wall is brought forward, the tendon of Horner's muscle is more or less stretched, and the sac bulges below and above it and is made prominent. Now, standing behind the patient who has such a lachrymal abscess that you are not able to enter the cavity through the puncta, you may take a knife, such as is known by the name of Beer's knife, or a bistoury such as is sold in the shops as Graefe's cataract-knife, and, holding the head firmly, poise the blade of the instrument flatwise, so as almost to be in contact with the cornea, pass it behind the internal canthus behind the angle where the lids come together, carrying the point inward and enter the sac, reaching it by making a slight wound. This wound usually heals readily, does not interfere with the canaliculi, and if it becomes fistulous it does no possible harm, because it is inside of the eyelids, and the sac empties itself inside instead of outside upon the cheek. I do not think you will find a description of this procedure in the books. Then, having emptied the sac, you may treat it afterward as the case may seem to require. You may subsequently slit up one or both canaliculi, in order to carry a probe into the sac; but never under any conditions cut into a lachrymal sac through the skin. You will meet with cases, probably, in which ulceration has gone to such an extent that the only thing which prevents the matter from coming out upon the cheek is a mere film of the cuticle, and with the finger-nail you can scrape through it; under these circumstances you may scrape through the cuticle, but never, in cases where you do not see the matter directly under the skin, make an opening into the lachrymal sac from the outside. There are two rules by which you should be governed in such cases: either enter the sac through a canaliculus, slitting up the canal if necessary, or open into it through the angle behind the canaliculus, just in front of the caruncle. I think that cutting into the sac through the cheek is in the highest degree objectionable.

CASE II.—*Stillicidium.*

This man complains of "water in his left eye," and he says it began "to run over" about a year ago. When he came under observation, it was observed that the lower lid was slightly everted, as it is now, and that there was stillicidium. Dr. Webster very properly slit up the lower canaliculus, carrying his incision as far backward as possible, and so cut through the wall close to the floor of the canaliculus, and yesterday he passed a probe on into the nose.

You must remember, in cases of stillicidium, to give directions to the patient to apply the handkerchief, gently pressing it toward the inner canthus when the tears are wiped away. If the eye is wiped outward and downward it tends to expose the conjunctival lining, causes it to become somewhat inflamed and swollen, and brings on such eversion as exists in this case. When the handkerchief is pushed toward the internal angle of the eye, sponging up the tears as it were, there is less danger of producing this condition of eversion.

The canaliculus is now open, and we will introduce Weber's probe and see if we encounter any obstruction. We will try the large end first, as it is always safe to do that, but it does not pass into the sac. We will next try the smaller end; it enters, and I now bring it into a vertical position. The end of the probe now rests on the bottom of the sac, and when it is in that position it is a wise thing to bring the thumb of the other hand up and feel for the sharp edge of the maxillary bone, and hold it there while the probe is passed through into the nose.

The thumb is brought up and held upon the sharp edge of the maxillary bone for the purpose of preventing the probe from breaking through the anterior sac-wall, and making a false passage over the edge of the bone and upon the outside.

In all these cases of catarrh of the lachrymal passages involving the canaliculi, the lachrymal sac, and the nasal duct, the mucous membrane is injected, and, not infrequently, more or less softened even in comparatively young subjects. And in many cases the lachrymal disease is made incurable by lack of caution upon the part of the surgeon; that is, as many a case of stricture of the male urethra is very seriously complicated or made incurable by incautious manœuvres of the surgeon. Nothing is easier in the male urethra than to make a false passage. It is the experience of all surgeons in cases of stricture of the male urethra that have passed through two or three hands, even of good general surgeons, to find one or more false passages. The temptation is so strong, when an obstruction is found, to overcome it, that it is almost irresistible. When you have a mound-like thickening of the mucous membrane standing up, down a little deeper, by the side of it, there will be a small crypt or fold of soft mucous membrane, soft like wet paper, and as you thrust the end of the instrument against this mound-like obstruction, which is tough and firm, it will be diverted into the little sulcus or fold-like pocket of soft mucous membrane, and through it passes into the submucous cellular tissue.

So I advise you, when you get the probe in this position, and are about to push it forward, to hesitate sufficiently to bring the thumb or finger up and feel for the sharp edge of the superior maxillary bone, allowing the thumb to overhang it slightly so as to steady the probe, and in that manner you will inflict the minimum amount of damage and the minimum degree of pain. I have in two cases removed a stile that was put in for disease of the lachrymal passages; but it had passed through the periosteum and was running down nearly to the ala of the nostril upon the outer surface of the bone.

My impression is that we shall see improvement in this case from the establishment of better drainage, and I would not resort to any further treatment for the present.

◆

A New Medical School in Russia.—A project for the creation of a faculty of medicine in the University of Odessa has been submitted to the Imperial Minister of Finance. The annual cost of the faculty is estimated at 127,000 roubles, and the construction of buildings at 600,000 roubles, of which the municipality undertakes to supply one-fourth.

Original Communications.

TRACHEOTOMY IN CROUP.

By ALEXANDER HADDEN, M.D.,

ATTENDING PHYSICIAN TO PRESBYTERIAN HOSPITAL, NEW YORK.

This operation is still struggling for a place among the well-recognized life-saving procedures resorted to by earnest practitioners of medicine and surgery. It has still to contend with popular prejudice on the one hand, and, on the other, the incredulity of medical men, who, in this instance, will be satisfied with nothing short of uniformly successful results.

Tracheotomy is still opposed by many highly intelligent practitioners, in face of the fact that thousands are yearly dying in cities where is to be had the best medical skill, with every appliance needful to secure favorable results by medical means alone; and notwithstanding that a careful study of the history and statistics of the operation discloses the fact that life has been saved by it in many instances where without it death was inevitable.

Tracheotomy—or at least laryngotomy—was known, it seems, to the ancients, and practised to some extent prior to the Christian era, for Cœlius Aurelianus, in writing of a disease of the pharynx and larynx, which we can readily recognize as diphtheria or membranous croup, speaks of Asclepiades, a physician of the first century before Christ, as having performed the latter operation.

Coming down to modern times, we find that tracheotomy was suggested on theoretical grounds by Dr. Home, as long ago as 1765. Subsequently to this period the operation was performed a few times, but without success, until in 1782 John Andre of London saved by it the life of a girl five years old. This is the first successful case on record.

But the operation did not seem to be received with favor, for we notice nothing more concerning it until some time after the beginning of the present century, when it was revived in France through the efforts of M. Bretonneau, of Tours. He performed the operation first in 1818, then again in 1824, in both cases without success. In 1825 he performed tracheotomy for the third time, and this time successfully, saving the life of his patient. He afterward operated upon a child three weeks old, and under circumstances otherwise very unfavorable, with entire success.

Since the time of Bretonneau, the most notable operator has been his pupil, M. Trousseau, who performed the operation more frequently than any other practitioner of his time, and with the following results: Out of 150 operations, 26 per cent. of recoveries; 1851 to 1854 inclusive, 24 operations with 14 cures, 58 per cent. In the last of these years, 1854, he had 9 operations with 7 recoveries, over 77 per cent. His success seems to have been constantly growing, his latest operations, taken *seriatim*, showing the highest average of recoveries.

M. Trousseau was not only the most successful operator of his time, but he was also the most ardent and persevering advocate of tracheotomy that ever lived. In his last publication he says that "he is determined to preach tracheotomy, and that with the greater conviction in proportion as the success of the operation increases, and to urge it upon practitioners as a *duty*, a duty as imperative as the ligature of the carotid artery after a wound of that vessel, though death follows that operation as frequently as recovery."

Tracheotomy has also been performed a number of times in Paris by Gery, Robert, Guersant, Jr., and others with varying success. The records of the Hospital for Sick Children, in Paris, for twenty-five years, show 2,351 tracheotomies for croup, with 614 recoveries. Also those of the Hôpital St. Eugénie, for twenty-two years, show 2,312 tracheotomies for the same, with 509 recoveries. At the latter institution we find the percentage of recoveries constantly increasing from first to last, if we except a single year—1864—from 12 per cent. in 1854 to 40 per cent. in 1876. In all the hospitals of France, taken collectively, the average of cures by tracheotomy seems to be about 30 per cent.

The results of tracheotomy in England are generally spoken of as being less favorable than in France. Yet Sir Thomas Watson reports 14 operations at the Middlesex Hospital within eight years, 7 of which, or 50 per cent, were successful. In two of the seven fatal cases the condition of the patients was hopeless before the operation was attempted.

As to the success of the operation in our own country, we have no reliable statistics to offer, with the exception of the publication by Dr. A. Jacobi, of this city, giving the histories of 166 cases operated upon by himself and by Drs. Krackowizer and Voss, with 39 recoveries, rather less than 25 per cent. Also the following in the neighboring city of Brooklyn. Dr. L. S. Pilcher, of that city, has with commendable industry collected the histories of 121 cases of croup, in which tracheotomy was performed, with 24 recoveries. This is not quite 20 per cent. The cases, however, in which Dr. Pilcher was himself the operator, show better results. He had 5 tracheotomies, with 3 recoveries, or 60 per cent. This is second only to the practice of Trousseau in his most successful year.

True membranous croup, by common consent, takes its place among the alarmingly fatal diseases of childhood. The record of vital statistics of this city (New York) shows that during the year ending December 31, 1878, there were 499 deaths from croup. There were also in the same period 1007 deaths from diphtheria; a disease which, according to the views of some practitioners, covers all cases of membranous croup. I do not wish to be understood as saying that all the cases reported as deaths from diphtheria were caused by suffocation; but many of these were doubtless due to that cause; cases which by myself and some others would have been considered as true membranous croup. This would have swelled very materially the number set down under the head of croup.

The immediate cause of death in membranous croup is, in most cases, mechanical obstruction in the larynx or trachea, from the presence there of false membrane, either closing the passage entirely, or so narrowing it as to prevent the ready access of air to the lungs; hence death occurs from suffocation. Now, in the case of a foreign body accidentally introduced into the trachea, and lodged there in such a way as to produce strangulation, we do not hesitate to cut down to the obstruction and remove it, if possible; why then should we, in a case of suffocation from membranous croup, hesitate to make an opening into the trachea below the seat of the obstruction, so that the air may have free passage to the lungs, and thus afford relief to the patient? Even if the disease have already made such inroads upon the constitution, and the vital powers are so far spent that recovery is impossible; still the relief afforded to the child struggling for breath is so great and immediate that we hold it to be the duty of the humane physician, if he cannot save the life of his patient, to give it at least an easy and painless death.

It is true that tracheotomy has been opposed by some medical writers of standing and ability, among whom may be mentioned Drs. Williams, Cheyne, Stokes, Mr. Ryland and Mr. Porter in England; and by Drs. Dewees, Eberle, and Stewart in this country. The expression of opinion antagonistic to the operation by these gentlemen is not, however, unqualified; for Mr. Porter is willing to admit that he cannot say that there are no cases of croup in which tracheotomy would be useful and proper. Dr. Charles West, while not favoring the operation, hesitates to express a decided opinion against it. Dr. Meigs, "while feeling himself," as he says "entirely justified in recommending the operation under certain circumstances, does not still feel at liberty to urge it strongly upon the parents of the child. He would state to them candidly its chances for success and its risks, and if they should throw the entire responsibility upon him, act as though the patient were his own child, and *advise the operation*." On the other hand, most of the medical authors of a later date, especially those of the present day, favor the operation.

Although it is not to be denied that medical opinion is yet somewhat discordant upon this subject, still we may be allowed to say that this is merely a verification of the old adage, "that doctors differ." They differ upon other questions as well as upon this; and it is only after long, careful, and painstaking clinical research that the profession can be brought into substantial agreement upon any question of medical practice.

Another surgical operation at one time considered dangerous, and therefore unjustifiable, was ovariotomy. There are many things in the history of this operation which bear a striking resemblance to the history of tracheotomy. This, like that, was also advocated on theoretical grounds long before its performance was attempted in practice. It was thus suggested by Wm. Hunter in 1762. Such indifferent success, however, attended the operation at first, that for a time it fell into disrepute, until Spencer Wells, by a series of brilliant and successful operations, brought it again into favor. Even in his hands the results were far from favorable at the beginning; but each successive series of operations showed an increased number of recoveries over the preceding series, somewhat as did tracheotomy in the hands of Trousseau. Of the first series of 100 cases operated upon by Mr. Wells, 66 recovered; of the second 100 cases, 72 recovered; of the third 100, 77 recovered; and of the fourth 100, 78 recovered. It was the opinion of this surgeon that the mortality might, and in some future time would, be brought down to ten per cent. His prediction has been more than verified. The mortality was subsequently reduced by Mr. Keith, first to one in seven, and then to one in ten and one-half. But in the five years immediately following, by the employment of Lister's method in the operation, the fatality was reduced to one in twenty-one. Finally, by means of this, together with the introduction of the clamp and some other improvements well known to surgeons, of the last eighty-one cases operated upon by this eminent surgeon, every one recovered!

Now, we do not look for any such remarkable results as this last in the case of tracheotomy, at any future time, however remote. The fact that this operation has for its subjects, children, in many cases very young children, instead of adults, as with ovariotomy, would, of course, preclude the possibility of any results at all to be compared with this; but, from the constantly increasing success of the operation in the hands of its most experienced and best known performers and most enthusiastic advocates, we may venture to predict that the time will come, and is now fast approaching, when tracheotomy will be universally recognized as a proper, nay, an imperative life-saving operation. At least, so far as our reading of the latest authorities extends, medical opinion seems to point in that direction.

Prof. Aitken says: "The evidence is daily accumulating that tracheotomy ought to be resorted to much oftener as a remedy for croup than it has hitherto been, and that at a much earlier period in the disease." And in substantiation of his opinion he states that in a wild district of Scotland, where croup is alarmingly prevalent, Dr. Cruikshank saved eight patients out of eleven on whom he operated in two years, by the timely performance of tracheotomy. Dr. Condie says: "That it may, in many instances, when timely performed, save the life of the patient, we have the most unquestionable evidence." Dr. J. L. Smith: "Few will deny, in the light of statistics, that tracheotomy is, in certain cases, proper, and that the physician at times would be culpable if he did not strongly urge its performance." Dr. Squire, in "Reynolds's System of Medicine," says: "No degree of severity in the general disease should interfere with this mode of averting threatened death from asphyxia, unless the presence of some other complication, necessarily fatal, can be demonstrated." Dr. Austin Flint: "The propriety of the operation hinges not on the number of cases in which it has proved successful, but on the answer to the question, whether any lives are saved by it. Now, it cannot be doubted that patients have been snatched from impending death by this operation. It is, therefore, not only justifiable, but the practitioner is bound, if possible, not to allow patients to die from suffocation for the want of its performance."

The balance of testimony thus appears to me to be largely in favor of tracheotomy. But, independently of this, and influenced by a long and earnest study of the subject in all its bearings, I am forced to the conclusion that the operation is not only a practicable one, but one that is imperative; in many cases the only expedient that can hold out the least hope of saving life; and that in all such cases the practitioner who neglects to urge its performance is remiss in his duty to his patients. Governed by such considerations as these, I have not hesitated to advise tracheotomy when the circumstances seemed to me to demand it. I have myself performed the operation a number of times, with what success will appear in the sequel.

CASE I.—My first case was that of an adult, a woman twenty-one years of age, by occupation a cook, who came to me in 1860 with laryngeal catarrhal stenosis, and on the point of suffocation. She had lost her voice several days previously, and had suffered much during the time from dyspnœa, continually growing worse. For the twelve hours last previous to the operation which I performed, scarcely enough air was allowed to reach the lungs to support life. She had already been subjected to every variety of treatment usually adopted in such cases, but without relief. I therefore advised tracheotomy, believing that that, and that alone, could bring relief. It was, in fact, about the only thing in the way of remedial measures yet left untried. The consent of the patient being gained, I proceeded to perform the operation without further delay.

Dividing the integument and intervening tissue with a scalpel, I made an incision through the upper rings of the trachea, just below the crico-thyroid membrane, and inserted a double silver canula. Breathing at once became easy, and no complications followed. She remained under my care for about four weeks, and then returned to her work, still carrying in her larynx the canula, which, on account of the organic lesion which had taken place, she was never afterward able to dispense with, though she had on several occasions made the attempt. Fifteen years afterward she returned to me wearing only the inner tube of the double canula, the outer one having become so corroded that no further use could be made of it. I examined the inside of the larynx in the attempt to discover, if possible, any cause why the tube could not be dispensed with. I found the mucous lining and the vocal cords thickened, but the larynx otherwise healthy. After thoroughly satisfying myself that her life was unsafe without the canula, I enlarged the opening and inserted another, which I presume she still wears. She complains of no disability otherwise.

CASE II.—C. B——, a lad six years of age, not of a robust constitution, but still enjoying usually good health, came under my care on the evening of December 13th, suffering from fever and sore throat. Pulse, 120; temperature, 103°. Tonsils red and slightly swollen, a little whitish exudation on each of them. As the boy had taken a cathartic of castor-oil during the afternoon, and this had operated well, I at once proceeded with the following treatment: I placed a napkin wrung out of cold water around his neck, ordered the patient to be kept in bed, and to take every hour during the night a teaspoonful of the following mixture:

Tinct. ferri chloridi,	
Sodæ chlor.	āā ʒ j.
Glycerinæ.	℥ ss.
Aquæ puræ	℥ ijss.

December 14th, A.M.—The fever had abated, but the throat was worse. The exudation on the tonsils had spread, and was clearly of a membranous character. The same remedy was ordered to be continued, and a gargle, ʒ ij. chlorate of potash to a pint of water, to be used. In the evening hoarseness set in, followed during the night by a croupy condition. The case was now taking on a more serious aspect; I therefore ordered the temperature of the room in which the patient lay to be maintained at 70° to 80° F., and the atmosphere to be kept constantly moist with steam. These directions were faithfully carried out.

In the afternoon the croupy cough continued. An application of a strong solution of nitrate of silver was now made, by means of a probang, to the throat several times during the afternoon and evening. This seemed to lessen the symptoms and check the exudation of membrane.

December 15th, A.M. — Seems better, but still croupy; pulse about normal; temperature 101°. On the night of the 16th patient grew suddenly worse, suffocation at times threatening. Membrane had extended to the larynx, and involved the vocal cords.

December 17th, morning.—The remedies hitherto employed having failed of their intended effect, I re-treated to the last position. Assisted by Dr. D. F. Leavitt, who put the patient under the influence of chloroform, I opened the trachea through the upper rings, and introduced a double canula of silver. This gave instant relief by liberating a large amount of mucus and membranous exudation which was loose in the trachea, allowing free access of air. The room was kept at a temperature of 75° to 80°, a sponge wrung out of hot water was placed upon the opening of the canula, and close attention given to keep the tube free. On the eighteenth day the tube was removed and the opening allowed to close up. I had made an effort, both on the eleventh and twelfth days after the operation, to remove the tube, but the larynx was not yet free. Recovery was attended by a sensitive condition of the optic nerve, which in a few months passed away, however, and the lad is now healthy and vigorous.

Case III.—C. B——, a girl four and a half years old, sister of Case II., was seized 15th of the same month, that is, two days afterward, with fever, followed by hoarseness and croup. As the other remedies had failed in her brother's case, turpeth mineral was given as an emetic, and for its alterative action; but to no purpose. On the 21st suffocation became so imminent that I decided to open the trachea, which, with the assistance of Drs. Leavitt and Irving, I did. The relief afforded by the operation was only temporary, as the false membrane had extended below the opening made, even to the larger bronchi, and to the lungs. On the 24th the patient died.

Case IV.—W. C——, a little boy, aged four years and a half. Was called to see him January 22, 1875. Had been hoarse for several days. Pulse quick, temperature 101°. Tonsils and posterior fauces slightly red. Could not discover any false membrane at first, but inferred from the history of the case that there must be false membrane, and afterward found it in the larynx and trachea. At 10 P.M. the dyspnœa had increased to that degree that his life depended upon the immediate performance of tracheotomy. Drs. Cremin, Schoonover, and Leavitt being present, by their approval, and with their assistance, the operation was at once performed, as described in Cases II. and III. The usual relief of breathing followed, and, with the exception of an attack of pneumonia on the upper right side, convalescence was uninterrupted. The canula was removed from the trachea on the seventeenth day, and on the twenty-second day the opening closed. No sequelæ in this case.

Case V.—M. D——, a male child, eighteen months old, came under my care on the night of April 15, 1875, with croup. Membrane visible on the tonsils and the sides of the pharynx, and had evidently descended to some extent into the larynx. On the 16th it became evident that the usual treatment had failed, and the dyspnœa had now become so great that death threatened from suffocation. I accordingly advised tracheotomy, and with the approval of Drs. Cremin, Schoonover, and Leavitt, I opened the trachea and introduced a double canula, which gave instant relief. The case progressed favorably. On the fifth day everything promised well. As the parents and nurses were of the laboring class, and not fully alive to the special care required in such cases, not aware of the great importance of keeping the tube free, I made it a practice either to call myself or send my assistant every night shortly after midnight, in order to be fully assured that all was going well. My assistant accordingly called at about two o'clock on the morning of the 6th, and found the attendants asleep, the tube filled with dry mucus, and the child dead. I examined the trachea below the opening made and could find no false membrane, nor even mucus. With greater vigilance on the part of the attendants this case would, without doubt, have recovered.

Case VI.—S. J——, a male child, three and a half years old. Was called in October 12, 1875. Found the patient suffering from true diphtheria. His nares lined with membrane, and an acrid discharge flowing from them. Tonsils and uvula also enveloped by membrane, and the cervical lymphatics considerably swollen. On the fourth day of my attendance the false membrane had extended so as to surround the rima glottidis, and was producing dangerous stenosis. To prevent immediate suffocation, with the approval of Drs. Leavitt and Schoonover, I opened the trachea and introduced a canula, which had the effect of permanently relieving the difficulty of breathing. The patient, however, died five days afterward in convulsions from uræmic poisoning.

Case VII.—J. S——, a male child, two and a half years old. Was called in to attend it on the evening of July 11, 1876. He had been ailing for several days; hoarseness had commenced the preceding day. On examining the throat false membrane could be plainly seen on the tonsils and on the mucous membrane surrounding the glottis. I applied an astringent to the affected parts, such as I had found of great value when the false membrane did not extend to the larynx. This was:

Liq. ferri. sulphatis	ʒ j.
Glycerinæ	℥ j.

Misce.

I also ordered lime to be slaked in the apartment, so that the patient could breathe its fumes. In addition, I ordered the bromine solution recommended by Dr. W. H. Thomson of this city, to be taken internally. But all these measures failed to give relief. On the morning of the 13th, when death was about to close the scene, with the assistance of Dr. R. C. Irving, I performed tracheotomy as above described. The patient was relieved for the time, but four days later he died, the false membrane having in the mean time extended to the bronchial tubes. The circumstances and surroundings of this case were highly unfavorable to its recovery; the apartment in which he lay had no ventilation to speak of, and was badly kept in all respects.

Case VIII.—A. H——, a little girl, five and a half years old, came under my care July 8, 1877, suffering from sore throat and nares. Patches of false membrane were to be seen on the tonsils and fauces. These were dissipated by the repeated application to them, by means of a throat-brush, of the solution of persulphate of iron and glycerine, in the proportions before ordered. On the 11th, symptoms of croup appeared. These increased, notwithstanding all ordinary means were taken to prevent—increased so rapidly and to such an extent, that by the morning of the 13th tracheotomy had become urgently necessary. With the assistance of Drs. Schoonover and Perham the operation was performed, and a double silver canula introduced. In this case the difficulty of keeping the tube from clogging up with plugs of dried mucus and shreds of false membrane was so great, the child being also very weak, often unable to bear the feeblest coughing, that to relieve this I resolved to apply to the inside of the trachea, by means of a feather, through the canula, the mixture of persulphate of iron and glycerine, for the threefold purposes of: 1st, coagulating the loose mucus in the tube, so that the child might the more easily free it by coughing; 2d, in order that the false membrane on the tracheal surface below the tube might be shrivelled, and thus be more easily detached; 3d, that the mixture might act as a local astringent to the inflamed surface which produces the false membrane, thereby changing it to the extent that it may cease to produce it. In this case and in the subsequent cases, this application seems to have fulfilled the requirements perfectly. After relief was thus obtained, the patient, with some suffering and distress, went through convalescence uninterruptedly, and is at the present time a well and healthy girl. In this case the canula was removed on the sixteenth day.

Case IX.—J. M——, male, thirty months of age. Was called to see him December 29, 1878. Found him in charge of Dr. Bleything, who had been in attendance for thirty-six hours previously. The doctor stated that the croup was well advanced when he first saw the patient, and that the membrane lined the fauces, and had already entered the larynx. He had thoroughly tested upon the patient the effect of breathing the fumes of slaking lime. It did not seem to give relief. I advised tracheotomy, and we proceeded to perform the operation forthwith, as the child seemed about to suffocate. The canula being introduced, relief was at once obtained. I continued to attend the case in association with Dr. Bleything, he attending to the details of the treatment. As in Case VIII., the persulphate of iron and glycerine was applied with the same good results, both to the fauces and to the throat, through the tube. The canula was removed on the twenty-fourth day, and convalescence went on uninterruptedly; recovery complete. I would here state that this same child was seized ten months afterward with the same species of croup and died, the parents refusing to have the operation again performed, on account of the trouble and anxiety that the former operation had caused.

Case X.—A. S——, a girl, six and a half years of age, was taken with croupous laryngitis, and was treated with the usual remedies, which failed to give any but the most temporary relief.

March 2d, a.m.—Death seemed imminent from suffocation. I therefore, with the advice and assistance of Drs. A. H. Smith and D. W. Perham, opened the trachea and introduced a silver canula. This gave the desired relief at once. The subsequent treatment was about the same as in the two preceding cases. The mixture of persulphate of iron and glycerine was freely used. Canula removed on the eleventh day after the operation. Recovery in this case took place slowly, but in the course of six weeks was full and complete.

Case XI.—J. S——, a lad, six and a half years old. I visited him first on March 7th, p.m. He had been hoarse for two days previously, and croupy for the past twenty-four hours. There was no false membrane visible on the tonsils or fauces. I was at first inclined to think the case one of catarrh, and to treat it accordingly; but on the morning of the 8th the croupy symptoms had become graver, and the membranous character undoubted. Suffocation threatened at times, and at 12 m., consulting with Dr. E. S. Bates, whose patient it was, I advised tracheotomy as the only means left that afforded any chance of relief, to which he assented. Dr. Gerster was also called in, who accorded with us in opinion. At 2 p.m., assisted by Drs. Gerster and Bates, I performed the operation. There was a little more hemorrhage than usual in this case, on account of the turgid condition of the veins, due to the spasmodic attack of suffocation which the anæsthetic did not fully relieve. The dyspnœa was relieved in a few seconds, and all distress allayed. The question as to its membranous character was settled by the patient's coughing up through the tube a membranous cast on the third day and shreds of the same on several occasions afterward. In this case Dr. E. S. Bates was associated with me until convalescence was fully established. The treatment was essentially the same as in Cases VIII., IX., and X. Tube was removed on the ninth day after the operation. On the third day after the removal of the tube several slight hemorrhages took place from the inside of the trachea, which created some alarm, but which were easily controlled by the astringent solution of iron and glycerine applied by means of a feather to inside of the trachea; also by the use internally of the fluid extract of ergot, six drops every two hours for twenty-four hours, and the application of ice to the neck by means of a rubber pouch. When the closure of the wound in the trachea was complete, all hemorrhage ceased.

The foregoing is the record of eleven tracheotomies done in my practice, with seven recoveries. With the exception of the first case on the record, the subjects were all children of tender age, about to die with membranous croup. I say, without hesitation, about to die, for subsequent conditions have confirmed this belief. This is about 66⅔ per cent. of the whole number, or 60 per cent. of the children. I will also state in this connection that of those who died, not in a single instance was death the result of the operation, either directly or indirectly; that in every instance life was prolonged and the most distressing symptoms mitigated. But for the accident or carelessness in Case V., I have reason to believe that I should most certainly have had one more to add to the successful cases of tracheotomy, which would have brought the percentage up to 72⅔. In all cases of children operated upon, where recovery took place, the opening made into the trachea closed up in three or four days, so that no air could pass, and it healed perfectly in about fourteen days after the removal of the canula. In some cases, however, slight granulations on the outer side appeared during the process of closing, but these were readily reduced by a few applications of sulphate of copper.

Rules and Requisites.—1. To operate as soon as I find that suffocation threatens, and that medical agents will not be likely to afford further relief.

2. To place the patient under the influence of chloroform, the anæsthetic which I prefer in these cases. Then provide and arrange for use the following instruments and articles: several towels, sponges, a basin of hot and one of cold water, a curved bistoury, two small scalpels, a director, an artery-forceps, plain dressing-forceps, two pairs scissors, a tenaculum (Langenbeck's, modified by straightening the hook), several goose-quills, well feathered. silk ligatures, and a double silver canula, armed with a tape long enough to reach around the neck of the patient, and tie.

3. Lay the patient on a table two and one-half feet in height, about the same in width, and long enough for the patient to lie at ease. and so placed that the light may fall upon the part to be operated upon.

4. Remove all clothing from the neck and chest, and place under the back of the neck a cylindrical body of say three to three and one-half inches in diameter and about ten inches long, wrapped in a towel, so that the head may fall backward, and thus throw the trachea upward, producing at the same

time some degree of tension of the tissues through which the incision is to be made.

5. To take up, between the thumb and index finger of the left hand, the integument overlying the part of the trachea through which the opening is to be made, and divide it with a sharp-pointed curved bistoury, and then, on the median line, work through the tissues and fascia down to the tracheal rings, by means of the finger-nail, director, and scalpel.

6. To open the trachea through the upper rings, paying no attention to the isthmus of the thyroid gland, commonly dividing it, unless it is found to be unusually large, in which case I would advise that it be pushed downward out of the way. Reasons for so doing will be given farther on.

7. To effect the opening in the trachea, I fix it by means of a strong tenaculum thrust through one of the tracheal rings, just below the crico-thyroid cartilage, and hold it firmly until I make the opening and place the canula in the new-made air-passage. This tenaculum I have modified so that it will divide with a slide, and open the trachea as my knife passed through the rings downward from it, thereby dispensing entirely with the use of retractors. This tenaculum is, I have learned since I had it made, a modification of Langenbeck's.

8. When the tube is once in place, and fastened around the neck by means of the tape, the next step is to free the parts of all blood and mucus, and whatever may be in the way, and to keep them so by the frequent removal and cleansing of the inner tube.

9. Replace the patient in bed. Keep a small sponge, wrung out of warm water as frequently as possible, over the canula. The atmosphere of the room ought to be maintained at a temperature of about 80°, and loaded with steam from boiling water containing lime.

10. To make application through the tube, by means of a soft feather taken from the tail or wing of a hen, of the solution of iron and glycerine beforementioned to the inner surface of the trachea. This may be done as often as every two or three hours during the day. This application has doubtless been an important factor in the good results obtained in the last four cases.

11. To remove the canula when the air can pass and repass through the larynx freely. This is easily determined by occluding temporarily the outer tube, or by removing the canula entirely for a few moments, and closing the artificial opening.

12. Give attention to the diet. Let it be mainly fluid in character, highly nourishing, and easily digested and assimilated. Let it, too, be given in small quantities and at frequent intervals. Have the bowels moved at least once a day, either by injections or cathartics.

13. Allow the opening in the trachea to close of itself, without any aid from adhesive plaster, compresses, or any such agents as might force the granulations to the inner side of the trachea. Should granulations spring up in the wound after it has closed, after it no longer admits air to pass and repass, apply a little powdered sulphate of copper once a day for several days, protecting the neck by means of a soft silk handkerchief tied around it.

In support of the operation above, and when necessary, through the isthmus of the thyroid gland, we quote from Linhardt, who opposes the making of the incision below this point, and says: "Not only on account of hemorrhage, but because of the entry of air into the left innominate vein, is injury of the infra-thyroid, if not actually fatal, yet one of the most dangerous accidents. Besides this, the trachea is frequently very deeply seated, and between it and the muscles arising from the sternum, there is so much cellular tissue that, in opening the trachea, a general emphysema is produced." This condition I once saw follow this operation, and when one of our most skilful surgeons was the operator. Death ensued, not from the operation, but from general emphysema. Dr. Jacobi reports two cases of death from the same cause. The introduction and fixation of the canula is also more difficult here. Hyrtl—Zeigliederungskunst—says: "Objection, too, is made to operating here on account of the danger of section of the laryngeal artery, which, though in size is out of proportion to the size of the larynx, is still only a branch between the superior and inferior thyroid arteries. The laryngeal artery, therefore, if not exactly parallel, runs in the same general direction as the contemplated incision, and does not, at any point, cross that line, nor is the line of incision crossed by any other important vessel; these considerations, together with the slight vascularity of the larynx, will point to this locality as the most appropriate one for the performance of tracheotomy." In practice I have found this opinion, based on the above anatomical reasons, to be correct.

The mixture of persulphate of iron and glycerine, which I apply to the inner surface of the trachea, I consider a very essential part of the treatment. Its salutary effect in the last four cases given above was remarkable, and contributed not a little, in my opinion, toward the recovery of the patients. It has the effect to coagulate the secretions poured out on the mucous surface of the larynx and tonsils; besides that, its astringent effect also extends to the underlying vessels, from which the secretions are derived, thus lessening their quantity.

A warm atmosphere, so 80° F., moistened with steam, charged with the fumes of slaking lime, has a very soothing effect, and I am inclined to believe that, when well applied, is more likely to give relief in membranous croup than any other remedy of a non-surgical nature known to the profession. I have a number of cases on my list which were doubtless going on rapidly to the stage where surgical interference would became necessary, but in which the disease was checked by its timely and faithful application. The mode adopted in administering the steam most effectively is to construct over the bed of the patient a tent-like enclosure, and keep the space within, where the patient lies, filled with the vapor of boiling water containing lime, and keep this up unremittingly, night and day.

It should be well understood that tracheotomy is not curative of croup: only a means of continuing life by preventing suffocation. Mechanically the continuance of medical treatment after the operation ought to be essentially the same as before it. This we wish to press with some degree of insistence, for we feel assured that harm has often resulted from the premature suspension of the treatment before the disease had been cured or had run its course. The keeping of the canula free by the frequent removal of the inner tube, and cleansing it from the mucus constantly discharging from it, is troublesome and requires the utmost care. For, should occlusion of the tube at any time occur, and it be not immediately cleared, the death of the patient would be the inevitable result, an accident which, as we have already seen, happened in one of my cases from the attendant falling asleep at a critical moment.

In order to obviate the difficulty just alluded to, attempts have been made to keep open the incision made into the trachea without the use of the canula. In order to effect this, Prof. Pancoast, of Philadelphia, after making the incision, cuts out a small triangular piece from one of the tracheal rings. This method is objectionable, however, on account of the contraction which takes place upon the healing of the orifice, thus lessening the caliber of the tracheal tube.

Dr. Martin, of Boston, however, has a plan which I think better of, and which I am disposed to try at the earliest favorable opportunity. He binds together the severed edges of the tracheal rings and the overlying integument by a single suture on each side of the incision. The ends of the thread with which the sutures have been made are left of a sufficient length to attach to the ends of an elastic band going around the neck. When fastening the bands, sufficient tension is made to separate the edges of the incision in front, and the band by its elasticity yielding so as to accommodate itself to any change in the size or situation of the parts produced by breathing or by the expulsion of extraneous products from the air-passages through the opening. The application of local treatment is also more readily accomplished when there is no canula in the way.

I am indebted for a part of the ancient history of tracheotomy to an unpublished manuscript of Dr. A. Jacobi, on Diphtheria. Also to Dr. E. C. Spitzka for some translations from the German authors quoted in the text.

155 East Fifty-first Street, New York.

A CASE OF SECONDARY PERITONITIS,

Treated with Enormous Doses of Morphia.

By ROBERT MILBANK, M.D.,
LATE HOUSE PHYSICIAN IN BELLEVUE HOSPITAL, NEW YORK.

Kate L——, æt. 22, married, domestic. Admitted to Bellevue Hospital, January 9, 1880. Patient's previous history and that of her family unimportant. She had never used opium or any of its alkaloids. Had always enjoyed good health until January 4th, when she had slight rigors, recurring several times at irregular intervals until January 7th. On that day she went out, and began to suffer from abdominal pain. On the following day she aborted, being at that time at about the fourth month of pregnancy. Since then has had constant and severe pain over the entire abdomen. Has had some diarrhœa and occasional epistaxis. Has not vomited. On admission, physical examination of her chest gave negative results.

Her abdomen was tender and painful, and somewhat tympanitic. There was a slight muco-sanguineous discharge from the vagina. Her tongue was dry and dark, and sordes were on the teeth. Rectal temperature, 105°; respirations, 23. I ordered sol. morph., U. S., ℥ j. hourly until pain subsided or respirations should be lowered to 12.

January 10.—Abdomen growing more tympanitic, pulse, 120, hard and small. Her respirations did not diminish in frequency, although she had the morphia hourly. Her temperature was 105°. She now had sp. vin. Gall., ℥ ss. q. 2 h. Turpentine stupes over the abdomen, and I ordered the nurse to give Magendie's solution, ♏x. q. 1 h., until her respirations should fall to 12. She received in this way ʒ iij., ♏ l. Magendie's solution, or seven and two-third grains morphia in the twenty-four hours.

January 11.—Her abdomen had become more tympanitic; pulse rather better; temperature, 104°; respirations, 19. Her mental condition was clear. On this day I ordered Magendie's solution hypodermically as before, increasing the amounts as indicated by respirations. She received, therefore, Magendie, ʒ iv., ♏ xxx., or grains ix. of morphia in the twenty-four hours, and sp. vin. Gall., ℥ ss. q. 2 h.

January 12.—Patient's condition about the same, except an extensive bronchitis which has set in. Temperature, 102°; respirations, 18. She received ʒ v., ♏ xl. Magendie's solution hypodermically, or eleven and one-third grains morphia in the twenty-four hours.

January 13.—Temperature, 104°; respirations, 20. Magendie hypodermically, ℥ j., ʒ v., or grains xxv. in the twenty-four hours.

January 14.—Temperature, 103½°; respirations, 22. Magendie hypodermically, ℥ j., ʒ iij., ♏ xl., or grains twenty-three and one-third in the twenty-four hours.

January 15.—Temperature, 102°; respirations, 23. Magendie hypodermically, ℥ j., ʒ iv., ♏ xx., or grains twenty-four and two-thirds in the twenty-four hours.

January 16.—Temperature, 101°; respirations, 25. Magendie hypodermically, ℥ j., ʒ xj. ♏ xl., or grains twenty-nine and one-third in the twenty-four hours.

January 17.—Temperature, 102¾°; respirations, 26. Magendie hypodermically, ℥ iij., ʒ vij., or grains lxij. in the twenty-four hours.

January 18.—Temperature, 102½°; respirations, 30. Magendie hypodermically, ℥ iij., ʒ vi., or grains lx. in the twenty-four hours.

January 19.—Temperature, 100½°; respirations, 26. Magendie hypodermically, ℥ iv., ʒ iij., ♏ xv., or grains lxxss. in the twenty-four hours.

January 20.—Temperature, 101°; respirations, 28. Magendie hypodermically, ℥ iv., ʒ iij., ♏ xv., or grains lxxss. in the twenty-four hours.

January 21.—Temperature, 100°; respirations, 27. A solution of morphia, double strength of Magendie's solution, grains xxxij. to ℥ j., was now given by the stomach; ℥ ij., ʒ vi., or grains lxxxviij. being given in the twenty-four hours.

January 22.—Temperature, 101°; respirations, 27. Tympanites much diminished, pulse slightly irregular when excited; countenance bright; slight delirium at night; regular passage from bowels every day. Double Magendie's solution by stomach, ℥ iij., or grains xcv. in the twenty-four hours.

January 23.—Temperature, 99½°; respirations, 26. Double Magendie's solution, ℥ iij., ʒ v. by stomach, or grains cxvj. in the twenty-four hours.

January 24.—Temperature, 99¾°; respirations, 20. Bronchitis nearly cleared up. Respirations increasing during the day. Morphia has been given in larger doses. Double Magendie's, ℥ iv., ʒ iij., or grains cxl. by the stomach.

January 25.—Temperature, 100½°; respirations, 21. Double Magendie's solution hypodermically, ℥ iij., or grains xcvj. in the twenty-four hours.

January 26.—Temperature, 101½°; respirations, 17. Double Magendie's solution hypodermically, ℥ ij., ʒ v., or grains lxxxiv. No movement from bowels for three days. Subsultus tendinum present.

January 27.—Is quite delirious, with constant muscular twitching. Has had slight epistaxis for four days. Tympanites has nearly disappeared. Temperature, 101¼°; respirations, 17. Double Magendie's solution, ℥ j., ʒ j. hypodermically, or grains thirty-five and two-thirds in the twenty-four hours.

January 28.—Temperature, 100½°; respirations, 19. Bowels not having moved, ℥ ss., ol. ricini given. Respirations increasing during day. Double Magendie's solution hypodermically, ℥ iij., ♏ vi., or grains ninety-six and two-fifths in twenty-four hours were given.

January 29.—Large movement from bowels. Patient much brighter and better. Tympanites but slight. Temperature, 102°, respiration, 21. Double Magendie's solution hypodermically, ʒ vi., ♏xv., or grains xxv. in the twenty-four hours.

January 30.—Temperature, 101½°, respirations, 21. Double Magendie's solution hypodermically, ʒ v., ♏xx., or grains twenty-one and one-third in the twenty-four hours.

January 31.*—Temperature, 101¾°, respirations, 19. Double Magendie's solution hypodermically, ℥ j., ʒ ij., ♏xxx., or grains xlij. in the twenty-four hours.

From this time patient steadily improved in all respects until February 25th, when a tumor made its appearance just below the free border of the ribs, in the axillary line of the right side. It was poulticed, and on February 28th, fluctuation being felt, I opened it and ℥ viij. of fetid pus mixed with blood were removed. The abscess was extensive but superficial. During this time the doses of morphia were being reduced, until March 1st, when she received Magendie's solution, ʒ ss. in the twenty-four hours.

On March 5th she commenced to menstruate, and continued to do so for a day and a half. She had occasional attacks of pain, and on March 16th received Magendie's solution hypodermically, ʒ ij. in the twenty-four hours, and up to this time has received altogether ℥ iij., grains xiij. morphia sulphat.

March 24.—Is now sitting up every day.

May 29th.—All morphia discontinued.

July 1.—The abscess, which has remained open and been discharging, has closed.

July 30.—Menstruated.

August 23.—Discharged cured.

Is now performing the duties of waitress in a restaurant.

The wide variations in the doses of morphia are accounted for by the fact that her respirations occasionally varied in a correspondingly irregular manner.

The points to which I desire to draw particular attention are:

1st. That the patient had never used morphia before her admission to the hospital.

2d. That the doses of morphia were increased with great rapidity without producing the full physiological effect of the drug.

3d. That they were decreased as the indications for their use diminished, with almost as great rapidity.

4th. That they were finally discontinued entirely without suffering to the patient.

5th. That but one small abscess in the arm was caused by the use of the hypodermic needle (and I think that could have been avoided), attributable, doubtless, to the fact that it was plunged deeply into the tissues, being really intramuscular rather than subcutaneous.

6th. That the mode of administration of the morphia was changed from hypodermically to adminisration by stomach, and back again to hypoderminically, without varying its effects upon the patient.

The tolerance for morphia in one unaccustomed to ts use seemed to point clearly to the need for it in such large doses, and if anything were necessary to add to the weight of evidence as to the freedom with which morphia may be used in this disease, as taught us by Dr. Alonzo Clark, I think this case would go ar toward furnishing such proof.

Progress of Medical Science.

Two Cases of Intestinal Obstruction Successfully Treated by the Application of Electricity.—Electricity has not hitherto enjoyed a wide range of applicability in the treatment of intestinal obstruction, although several cures have been reported to have followed its employment. Dr. M. Boudet, of Paris (*Le Progrès médical*, August 14th and 21st, 1880), reports two new cases, which were apparently saved—one from imminent death, the other from the doubtful chances of a dangerous operation—by the use of this new therapeutic agent. The report of his cases is additionally interesting from the fact that he employed the constant current, whereas others have, as a rule, chosen the method of faradization. His first case was that of a girl, aged 15, who was attacked by an acute peritonitis, which soon became general, and confined the little sufferer to her bed for about a month. During convalescence she was suddenly seized with severe abdominal pains, and began to vomit profusely. Her pulse grew small, rapid, and feeble, her facial expression became pinched, and all rectal evacuations ceased. Soon her abdomen became tender to the last degree, and it was now no longer doubtful that the gut was obstructed by peritoneal bands or adhesions. After unsuccessful attempts to effect a cure by ordinary treatment, the application of electricity was commenced. The negative pole was placed in the rectum, and the positive pole upon the umbilical region, which appeared to correspond to the site of the obstruction. Visibly energetic contractions of the intestine were thus produced, and the treatment was persisted in, although the first trials did not appear very encouraging. Two days later, after an attack of intense painfulness in the umbilical region, a rectal evacuation followed the application of the constant current. From this moment convalescence was established, and rapidly progressed to perfect health. The use of electricity had been prolonged over an hour at each sitting, and had been repeated several times during every twenty-four hours.

Case II. was one of obstruction by accumulation of fæcal matter in a man aged 60, who was a sufferer from chronic constipation caused by intestinal paralysis. Prof. Gosselin, who was called in consultation, advised an operation, but consented to a previous trial of electricity. Accordingly, Dr. Boudet introduced a uterine sound into the rectum, connected this with the negative pole of a battery (Gaiffe), and placed the positive pole on the abdomen. The current was gradually increased, and after twenty minutes, when fourteen elements were in action, gurgling sounds were heard, which proceeded from the contracting intestine. Now the current was interrupted, and for ten minutes more the abdomen was subjected to faradization. Similar treatment was maintained for several days, during which time the patient visibly improved, and at last completely regained his health.

In the remarks appended to the description of these two cases, Dr. Boudet observes that electrical excitation evidently produces intestinal contractions, and that the movements of the gut may suffice to cause the reduction of a volvulus, invaginations, or strangulations. Matters occupying the lumen of the digestive tract may also be discharged by this means. The physiological researches of Duchenne, Legros, and Onimus, of Tripier, and Heurot, all speak in favor of this view. Continuous and permanent currents are therefore recommended for the treatment of intestinal obstruction, especially when there exists a condition of paralysis or paresis of the gut. The induced current may, nevertheless, be employed to aid self-reduction, by its action upon the abdominal muscles, exciting them to violent contractions. This shows that a single method of applying electricity will not answer in every case of intestinal obstruction, the variations depending upon the differences in the nature of the occlusion, differences which have special indications in every given case. Finally, attention is drawn to the fact that initial failures should not discourage one from the repetition of electrical treatment.

Ten Cases of Litholapaxy.—Dr W. W. Greene, Surgeon to the Maine General Hospital, reports ten cases of litholapaxy, and supplements his account of them by some explanatory statements. All the patients were thoroughly etherized. None of the cases, except the tenth, gave any evidence of renal disease. In all but this case the urine was previously analyzed and the capacity of the bladder approximately estimated. In each of the nine cases of litholapaxy consent was obtained and arrangements made for immediate lithotomy in case of failure, from any cause, to complete the litholapaxy. In five out of the nine cases, slitting of the external meatus was necessary. It was noticeable that in no case was the operation followed by cystitis or septicæmic fever. In the first six cases some of his familiar lithotrites were used (Civiale's, Thompson's, Teevan's, and Mercier's). In the seventh, eighth, ninth, and attempted tenth, Bigelow's instrument was used. Dr. Greene believes that, in the hands of a skilful surgeon, any good lithotrite may do the crushing satisfactorily in litholapaxy. Still, he prefers Dr. Bigelow's instrument to the others, for reasons clearly stated by the latter in his monograph. But even this lithotrite will sometimes clog or hold fragments unless the surgeon is very careful. In each of the first nine cases reported, the bladder was completely emptied at one operation, and the patients all remained free from any symptoms of calculus up to the date of the report. In no case did incontinence or any other unpleasant consequence follow the use of the large tubes. In no instance was there but the most trifling hemorrhage—the tenth case gave much more than all the rest—and in four cases not a drop of blood was seen from first to last.—*Reprint from the Boston Medical and Surgical Journal*, 1880.

Locomotor Ataxy and Cardiac Lesions.—At the general hospital of Montpellier, Dr. Grasset, *Gaz. méd. de Paris*, Aug. 21, 1880, had occasion to observe manifest cardiac symptoms in conjunction with two cases of locomotor ataxy. (*Montpellier Médical*, June, 1880.) The question arose whether this was merely an accidental coincidence, or whether the two lesions stood in causal relation with each other. In 1879 Berger and Rosenbach (*Gaz. méd. de Paris*, p. 459) reported seven cases of aortic insufficiency occurring in ataxic patients. To this number Grasset was able to add fifteen other cases, where a cardiac lesion existed together with the affection of the cord. In most of these cases, as also in the two observed by himself, the form of the disease had the painful type (forme douloureuse). This circumstance led the writer to believe that a direct action of the cord on the heart did not take place. In his opinion the cardiac troubles are a secondary manifestation proceeding from the reflex action consequent upon the painful sensations. He supports his views by calling to mind the recent investigations of French and Teissier fils, who demonstrated the marked influence that excitation of sensory nerves exercises on the circulation and respiration. Potain's studies are also alluded to, studies which established the fact that gastro-hepatic disorders may cause, in a reflex manner, disturbance of the right heart. Intense, prolonged, and frequent pains, have, according to Grasset, a direct effect on the heart, thus disturbing the circulation and giving rise to lesions. For this reason locomotor ataxy may prove the reflex cause of cardiac trouble, not because it is a disease of the spinal cord, but because it is a painful affection. Considering the small number of such observations, as contrasted with the frequency of cardiac disease, all such theoretical explanations must be received with great reserve. We certainly need more extended and fuller observations before we can accept this new pathogeny as a solution of this interesting coincidence of the two morbid conditions.

Progress in the Treatment of Stricture of the Urethra.—Some remarks were made on this subject by Sir H. Thompson, at the annual meeting of the British Medical Association, in Cambridge, August, 1880. As illustrations of this advance during the last thirty years in England, the doctor mentioned five points:

1. A general recognition of the principle that a delicate and gentle manipulation of any instruments in the urethra is alone trustworthy or permissible, in the place of that which was formerly greatly prevalent, viz., that urethral obstruction might often be overcome mainly by force.

2. The substitution of very pliable and taper instruments for silver and stiff gum-elastic instruments in much of the treatment, both in ordinary and in continuous dilatation.

3. A more general acceptance of the doctrine that, given time, patience, and gentle handling, very few strictures should be met with which cannot be fairly and successfully traversed by an instrument passed through them into the bladder. At the same time, an undoubted improvement is to be noted in the mode of operating for those exceptional cases in which the surgeon fails to accomplish that object.

4. A more general acceptance of the doctrine that dilatation of the urethra, whether with or without incision, may be carried with advantage to a somewhat higher degree than had for some time previously been regarded as desirable.

5. The substitution of internal urethrotomy in some form for the application of caustics, and for external urethrotomy on a guide. Each of the topics named is then considered somewhat in detail. In connection with the subject of the "calibre," or "diameter" of the urethra, or the amount of its dilatability, he refers to Dr. Otis's revival of the theory of "the large diameter of the urethra." He records his sense of the value of this point, but he adds that "it is a very easy thing to damage irreparably some individuals by overdistending the urethra." Thompson also opposes another doctrine which is associated with the preceding, viz.: that stricture of the urethra is permanently cured by complete division of all the diseased tissues affecting the passage. In speaking of the many methods of performing internal urethrotomy, he says that the principles which govern a sound procedure are more essential points for the surgeon to discover

and to teach, than a consideration of small details. These principles he briefly states as follows: 1. The necessity for a physical examination before operating, to detect and estimate the narrowed portions of the urethra. This is best accomplished, in his opinion, by means of a series of metal bulbs on slender stems, taking care not to regard as changes of disease those points at which the urethra itself is naturally only slightly dilatable. These bulbous exploring sounds he invariably used, advocating them as essential to diagnosis, in his first work twenty-six years ago. He still prefers them to any others, as safer, less irritating, and not less efficient than more complex instruments which have been devised. 2. The necessity for accomplishing a complete division of all the morbid tissue constituting the stricture, by an incision carried through it, no matter what part of the urethra, or how much of it, is involved in the disease. As a general rule, he thinks, this is most efficiently done by a slender blade, carried beyond the stricture and made to cut from within outward; this latter proviso being, however, an open question. The important point is that any alleviation of the patient's condition attained by operation will be transitory if any part of the narrowing be left undivided. 3. He regards it as essential, after such division, to place at once a full-sized catheter for some hours in the bladder, to ensure a free outlet for the urine, and prevent all possibility of extravasation of urine into and through the incisions thus made. 4. The necessity for passing full-sized bougies subsequently, at occasional intervals, in order to effect free distention of the walls of the urethra, which lie in almost constant apposition, and so to prevent reunion of divided surfaces by the first intention. Finally, he declares that the great desideratum of the present time unquestionably is the discovery of a mode of treatment which shall permanently restore to the strictured passage its original dilatability; and he adds that a thoughtful consideration of the pathological condition which constitutes organic stricture does not embolden him to hope that such a result can be insured by the application of any principles of action at present known to us.—*The British Med. Journ.*, August 28, 1880.

NOISES IN THE HEAD.—Much distress is occasioned to the subject of aural disease when he is ignorant of the conditions to which noises in the head owe their origin. Dr. Samuel Sexton offers an explanation of the modus operandi of these phenomena, deducted from his researches in the disorders of the middle ear. They are due, he believes, to anomalies of the drum-head and the small bones of the ear, structures composing the conductive apparatus, which, in a normal state, protect the patient from a cognizance of the somewhat noisy performance of the body's natural functions. In order that this normal duty may be performed, the drum-head and small bones of the ear are found to be suspended, as it were, in a state of tension between the outside air and the fluid in the labyrinth, thus effectually responding to wave-sounds from without, but ineffectually to those from within.

It is to be inferred from Dr. Sexton's explanation that the normal arrangement of the conductive mechanism is such that protection from tinnitus aurium is thus afforded to the auditory nerve, inasmuch as otherwise interference would obtain. In other words, the perceptive sense would be occupied at the same moment with disturbing noises from within the head, as well as with the undulations of sound that arise from sources without. The complete and satisfactory apprehension of the latter by the perceptive faculty requires that noises within the head should be excluded.

When the drum-head, either from acute or chronic disease, is rendered tensile, or the articulating surfaces of the small bones from similar influences become ineffective, the patient at once hears the sounds that arise within his own body, more especially those of the head, to which he was hitherto a stranger. Many of the sounds which thus become audible are well known to be most distressing, especially to weak-minded and nervous people. Some of the most annoying of these subjective symptoms arise from the patient's own voice (autophony), his own acts of swallowing and eructation, and from the impulses imported by the current of blood which traverses the carotid canal in its curvature near the middle ear; the last-named impulses causing a throbbing, pumping, or gurgling sound. The disordered movements of the conductive mechanism itself sometimes give rise to discordant noises of an intensely disagreeable character. The author's clinical experience has led him to the conclusion that many anomalies of audition, hitherto supposed by him to arise from abnormalities in the inner ear, are really due to pathological conditions of the conductive apparatus.—*The British Medical Journal*, June 26, 1880.

STATISTICS RELATING TO THE SEAT OF CHANCROUS AND CHANCROID ULCERS IN WOMEN.—Dr. Razumoff tabulated 1,374 cases, treated in one of the Moscow hospitals, as follows: Ulcers were seated on the uterine cervix in 117 cases (8.5 per cent.); 13 of this number were chancres with subsequent general infection; 664 on large and small labia; 272 at the vaginal entrance and between mystiform caruncles; 176 on posterior commissure; 60 on the perineum; 55 about anus; 26 anterior commissure; 3 in different parts of vagina, and 3 on meatus urinarius.—*Meditz. Obozrenie*, p. 360, May, 1880.

LOCAL USES OF PEPSINE IN DIPHTHERIA.—Dr. K. Danilewsky recommends the following formula; ℞. Pepsine wine, ℥j. to ʒiss.; acidi. muriat. dil., gtt. xv. to xx.; aquæ dest., ʒvj. S.—To use as a mouth wash or gargle four times an hour, for five to ten minutes each time, Medicine should be kept in water-bath, 37° to 40° C. Local applications of it with a brush can be used also. Dr. Wischinsky speaks also very favorably of this treatment.—*Vratch*, 1880, No. 18.

TREATMENT OF EXCESSIVE PERSPIRATION OF HANDS AND FEET BY FARADIC CURRENT.—As this symptom is due to disordered functional activity of peripheral nerves, Dr. Gordon was led to study this particular condition with the following results: the tactile and faradic sensitiveness of these parts is diminished, their temperature is lower. Systematic faradization controls the perspiration, and corresponding to the effects of treatment, the above two conditions are relieved.—*Vratch*, 1880, No. 20.

ATROPIA AS A SUBSTITUTE FOR MORPHIA FOR THE RELIEF OF PAIN.—Dr. Wrightson, of Newark, N. J., reports a case of cholera morbus in which the intense pain was instantly relieved by one-eightieth grain of atropia hypodermically, after the failure of thirty minums of Magendie's solution of morphia. The patient was on board of a pleasure yacht, and the atropia, Magendie's solution, and a hypodermic syringe comprised the doctor's armamentarium.—*Maryland Med. Jour.*, Sept. 1st.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, October 23, 1880.

CLIMATE CURE.

It is humorously said by the laity that, when all other plans of treatment fail, the patient is sent away to try another climate. With such a belief that this method of treatment is a last resort, and that the physician is driven thereby to the desperation of relinquishing a profitable patient, it is no wonder that it has taken a long time to establish in the minds of the people, and with some part of the profession as well, the value of what may now be called the simple climate cure. But that the study of the latter is growing in importance goes without the saying. Judging from the number of pamphlets and books we receive bearing upon the advantages of this or that climate for invalids, it would appear the theme is a wide one and its advocates very many. Having no particular locality in mind, and desiring to make a few general remarks upon the subject, we are safe in saying that there is altogether too much special pleading, on the part of the writers in question, to divest their opinions of a natural partiality for the localities in which they live and practise. Divesting the writings of this element, which is to a certain extent excusable because natural, we find in them much for study and contemplation, and much to guide us in choosing a particular locality as a temporary or perhaps permanent residence for our patients. For instance, we have laid before us a collection of facts regarding humidity, temperature, wind velocity, rainfall, and soil drainage which are of the greatest possible importance to the general practitioner in enabling him to make a proper selection for his patient. In attempting to do so, however, more than ordinary discrimination is necessary and more than ordinary responsibility is involved. If the physician is not sufficiently acquainted with a given locality, it is much better for his patient to stay at home. The advice should be founded on just as good reasons, and with as much care, as in prescribing any other method of treatment. In fact, many more things are to be taken into account than are usually necessary in a casual prescription. The patient has not the advantage of stopping his medicine, in case it disagrees with him, and of substituting therefor something that may not be positively detrimental.

Possibly the reason why the prevalent loose way of prescribing change of locality to patients, without even more disastrous results than is sometimes obtained, is due to the fact that those with phthisis, and who are proverbially hopeful, are usually selected. But that the changed conditions of life, even in this class, oftentimes tends to strike the balance the wrong way, is a fact that has been brought home to the experience of very many whose advice is sought in these cases.

At a time in the year when so many invalids are seeking advice as to change of quarters, these general observations seem to be called for. Considering the number and variety of well-established health-resorts now in successful operation in our own country, there would seem to be an embarrassment of riches in making a choice. There are no doubt climatic facilities for the treatment of all varieties of phthisis or of any other intractable disease, but the trouble is to use them properly. The careless prescriber, however, is so constantly trying to fit the square plug into the round hole that there seems to be a necessity at certain times to remind him of the impracticability of such an endeavor.

The conditions to be taken into account in prescribing a change of climate are numerous and important. Taking phthisis as the typical disease for which this plan of treatment is mostly employed, we have its varieties, its different stages, the age of the patient, condition of general health at the time, and many other conditions to consider before deciding upon any special plan of climatic treatment. The choice of place and climate in this country is probably better than in any similarly accessible region. We may safely say that we can command, within a few days' travel, any range of temperature, humidity, high or low level, that can possibly affect the treatment of any of the varieties of phthisis. From the Adirondack woods to the coasts of Florida, from Minnesota to Colorado, from the Pacific coast of California to the Bahama Islands, and from the arid plains of New Mexico to the pine forests of Georgia, we have a range of selection which must needs satisfy the most exacting requirements of every stage and variety of disease for which change of climate is prescribed. This condition of things is so well acknowledged by our European contemporaries that America is claimed by them to be the country which offers a far greater choice of climates than is to be found across the Atlantic. In no country can the climate cure of this dreadful disease be more satisfactorily settled.

So far we are quite well agreed that there are certain principles tolerably well established upon which the climatic method can be based, but that there are still some differences of opinion upon certain points must be also acknowledged. For instance, we know on general principles, that the catarrhal variety of phthisis does not do as well in high altitudes as on lower levels, and that the contrary is the case with the fibrous variety of the disease. For the tubercular variety the equable climate, whether warm or cold, whether moist or dry, seems to be indicated. In still other cases, especially in middle-aged, broken-down persons, a sea voyage is likely to be beneficial. But as each case must be treated by itself, it can easily be seen that too much care cannot be taken in weighing all the chances of the change and of offsetting all the enthusiastic descriptions of different sanitaria by the more or less inevitable privations of home comforts and pleasant social surroundings. Concerning the latter points there is not so much discretion used as there should be. Not only must a proper diagnosis be made of the character of the disease, its stage and progress, but the previous habits of the patient must be taken into account. Very often the social proclivities of the patient are more important in taking into account his chances of recovery than any change of climate can possibly be. On second thought this appears so much like a self-evident proposition, that its presentation would hardly seem necessary, except for the fact that it is constantly lost sight of by a large majority of prescribers. To send a patient away from his home appears a simple procedure; but in reality the magnitude of the sacrifice which it involves is seldom appreciated by the physician, and almost never by the invalid, who for the first time is to separate himself from his family and friends. Home comforts are often replaced by the most annoying inconveniences. In some of our most healthful climates the food is deficient in quality and variety. Game may be abundant, but man cannot live on game alone. The absence of fresh meat is much complained of, as is also the quality and choice of fruit in other places. Then again, in many places the charges for accommodation are very high and tempt the economical to lose in one way from lack of home comforts what they might otherwise obtain from the delightful climate. The general advice to be given in regard to such possibilities is that the patient, unless he is perfectly easy in money matters, should not go at all; that under proper circumstances, having concluded to start, he should select a well-regulated sanitarium in the district, where the nearest approach to home comforts could be obtained, where mail and other kindred facilities exist, and where there are meat and vegetables in reasonable abundance. That many of these deficiences exist in even well-regulated establishments, we have good reason to know from many complaints we have received from different quarters, and we take this occasion to refer to them, as more than possibilities in some general and necessarily cursory remarks upon the climatic treatment of disease. For obvious reasons we have omitted a reference to any particular localities, but merely give some general directions founded on general reading and observation, which each physician may apply to the individual necessities of the cases under his care. It is perhaps unnecessary to say in this connection, that climate cure is a science in itself, that it should be studied as a science, that as a system of treatment it is a powerful one for good or evil, and that as such it should be used with intelligence and discretion.

THE PROTECTION OF THE INSANE AND THE PREVENTION OF INSANITY.

We have received a pamphlet containing the three addresses delivered at the time of the organization of the National Association for the Protection of the Insane in Cleveland last summer. The first address, by Dr. George M. Beard, presents with much force the reasons for the creation of the society in question. The undoubtedly rapid increase in the number of the insane, and their peculiar helplessness and weakness are alone, we are told, sufficient cause for establishing an organized watch over the disease, its victims, and their keepers. "We have," says the speaker, "societies for the prevention of cruelty to children; but the insane are children without their *naïveté*, their innocence, or their sweetness; we have societies for the prevention of cruelty to animals, but insanity oftentimes reduces man below the grade and habits of the lowest animal; we have societies for relieving the condition of the poor, but insanity makes us poor, while poverty makes us insane. We have health boards for the warding off of fatal epidemics, but death, even at the hands of the foulest disease, is poetry compared with hopeless disease of the mind." Another reason given for creating the association is that it will help to bring about a state supervision of the insane. And such supervision, properly carried out, will give in this country, as it has in Great Britain, assurance that the insane in asylums, public and private, will be treated kindly and wisely.

Such a society will also, it was claimed, help to raise the standard of thought and treatment of the insane, both in and out of asylums. The care of the insane is one that must interest not only physicians, but politicians, economists, and philanthropists, and this includes a large number of persons who are now ignorant of the disease in many of its aspects. To infuse throughout society a true notion of the character and dangers of insanity and of the needs of the insane, would afford plenty of scope for organized effort.

We can heartily subscribe to the sentiments thus quoted. The Association for the Protection of the Insane has truly a wide enough field before it, and we are glad to learn that it has already secured, as members, men and women who will be sure to accomplish good work in the cause for which they are united.

The address of Dr. Shaw on the practicability and value of the treatment of the insane is a plain and modest statement of what he has done at the Flatbush Asylum, during the past two years, in the way of introducing non-restraint. The simple statement of facts that he gives is the most powerful argument we have seen for the system in question. In two years Dr. Shaw has turned one of the worst ayslums in the State into one of the best. With the difficulties which he had to contend against he cannot be too highly praised for this work. Dr. Seguin's address treats of the same subject, but more elaborately, and with reference to the personal rights of the insane as well as to their proper therapeutical treatment.

Altogether, we can congratulate the society that it was inaugurated in so successful a manner, and that its first work is so worthy of the high aims which it professes.

THE INTERNATIONAL LARYNGOLOGICAL CONGRESS.

THE International Laryngological Congress, which met at Milan last month, appears to have been a very successful affair. Italy, Germany, England, France, Russia, and America were represented. A very interesting discussion took place upon tuberculosis of the larynx. Some of the German professors claimed to have cured this affection—a claim which will give strength to a similar one that has been made by some American laryngologists.

A very interesting case was exhibited by Professor Caselli of complete removal, twelve months previously, of the larynx, pharynx, base of the tongue, soft palate, and tonsils, for an infiltrating lymphoid growth, interfering with respiration and deglutition. The patient appeared in excellent health, swallowed easily both liquids and solids, and spoke distinctly by means of an ingenious apparatus acting after the manner of a clarionet.

The members of the congress were entertained with an excursion, two collations, and two cremations. The latter excited much interest, as they illustrated two different methods of incinerating the corpses. The one was done with the ordinary furnace, wood-fire, and iron griddle. The latter was a new process, the combustion being entirely by gas.

The hospitalities extended to the guests were very cordial, and appeared to have been greatly enjoyed. This was the sixth International Congress that has occurred at Milan this year, the others being representatives of ophthalmology, otology, public health, history, and the teaching of deaf-mutes.

THE HISTORY OF OVARIOTOMY.

A QUARREL has been going on in the *British Medical Journal* upon this subject. It arose from an editorial article which, in reviewing the history of ovariotomy, gave only slight notice to the work of Dr. Charles Clay, but heaped the honors upon Mr. Spencer Wells. This was resented by the former gentleman, who claimed that he was the first prominent ovariotomist in England, and had done a great deal to put the operation on a solid footing; also, that much which the *Journal* had ascribed to Wells should have been ascribed to him (Clay). He also said that Spencer Wells first saw him operate in 1857, fifteen years after his first operation, and that as Mr. Wells had not at that time operated at all, he then learned much regarding the operation. Dr. Clay also claims to have used the intra-peritoneal suture before Wells demonstrated its value by experiments on animals.

Mr. Wells, on the other hand, denies that he ever saw Dr. Clay operate until 1863, at which time he (Wells) had operated fifty-eight times. Various letters and editorial comments have appeared upon this matter, the last being a letter from Dr. Clay, in which he reaffirms his statement that Wells saw him operate in 1857, and he brings considerable evidence to substantiate his point.

Reports of Societies.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, September 22, 1880.

DR. T. E. SATTERTHWAITE, PRESIDENT, IN THE CHAIR.

DR. HEINEMAN presented, on behalf of a candidate for admission into the Society, a specimen of sacculated aneurism of the aorta, which, although of small size, had, in consequence of its impingement upon the last dorsal, ruptured prematurely, and had caused an immense subperitoneal hæmatoma.

ADHERENT PLACENTA.

DR. F. V. WHITE exhibited a specimen of adherent placenta with the following history: Mrs. M——, aged twenty-six years, primipara, was taken in labor September 20th, 10 P.M. 2.30 A.M. of the 21st the bag of waters broke. The os uteri was dilated to the size of half a dollar, and was dilatable. She was delivered at 10.30 A.M., after a natural but severe labor. After separating the child from the mother, Dr. White wrapped the cord around one hand, and made moderate traction in the direction of the superior strait, the fundus uteri being held in the meantime by the opposite hand. Shortly the cord broke, and Dr. W. then found it necessary to introduce the hand into the uterus. He then discovered that the placenta was adherent to the anterior portion of the uterus in the median line, where the membranes were also thickened. The woman was placed upon her side, the womb steadied with one hand, and with the other the placenta was duly separated. Considerable hemorrhage attended the operation. The specimen was interesting to Dr. White as it was the first of the kind that he had seen during his obstetric experience, comprising an attendance on 2,000 cases of labor.

In answer to a question from Dr. Tausky, as to whether he used Crede's manner of compressing the uterus before attempting traction upon the cord, Dr. White stated that he did not think that compression availed much in such cases as the one under consideration. Immediately after the child was born, Dr. White stated that his practice was to make firm pressure upon the uterus, and, if in a reasonable time the placenta was not discharged, it was his custom to help nature by making careful and moderate traction upon the cord ; at the same time the placenta was gently freed from its connections.

Dr. Tausky believed that by pulling on the cord there was danger of producing inversion of the uterus, especially when the placenta was adherent.

In answer to a question from Dr. Satterthwaite, **Dr. White** stated that he was not in favor of using ergot in such cases as the one presented.

Dr. Tausky remarked that he had seen several cases of adherent placenta. All of these were complicated with placentitis. He was in the habit in such cases of using Crede's method combined with the use of ergot. If both these means failed, he introduced his hand into the uterus, and separated as much of the placenta as was possible. The hand failing, the curette was employed, and the remaining parts were detached piecemeal. For the hemorrhage which usually attended this operation he used hot-water injections (110° F. to 125° F.). The injection was continued for half a minute, and then there was a rest for an equal period of time. This plan was continued until the hemorrhage ceased. If it be impossible to remove the entire placenta without using force, he thought it was much better to wait.

Dr. Sell stated that he had met with several cases of retained placenta. He referred to one of these which occurred after the delivery of an acephalic double-faced monster. Three-quarters of the placenta was entirely adherent, and was removed piecemeal. In regard to the relative merits of forcibly removing the placenta and of allowing it to remain until discharged by nature, he had witnessed the effects of both practices in the University of Vienna. The results were in favor of allowing part or all of the adherent portions to remain. In none of the cases in which the latter practice was followed was there any bad result, and in none was there any hemorrhage.

ANEURISM OF AORTA.

Dr. Peabody presented a heart removed from the body of a male waiter, aged thirty-nine years, a native of Switzerland. Unfortunately, the patient died an hour after his admission into the New York Hospital. The history of the case was incomplete and unsatisfactory so far as it was obtainable. The patient had been ailing for several months, but he was able to follow his occupation until four or five days before admission. He was examined by the house physician. The heart was large and feeble in pulsation, but without murmurs. There was fluid in both pleural cavities, and he was in the condition of general anasarca. He died without premonitory symptoms, after being put to bed in the ward.

At the autopsy there were six hundred cubic centimetres of fluid found in the pleural cavities, and half the quantity in the cavity of the peritoneum. The conditions of the heart and aorta were the points of interest. The left ventricle was thin, and was markedly dilated. The aorta was atheromatous, and at its commencement and on its anterior aspect was dilated, forming an aneurism large enough to contain half a hen's egg. It contained both old and recent clots. The aortic valve was normal, but would not have been incompetent except for the dilatation above it. The muscular tissue of the heart was distinctly fatty, the deposition of fat being more on the right than the left side.

Dr Heitzmann objected to the use of the term deposition of fat, inasmuch as it did not express the true pathological condition of fatty degeneration. The latter was an actual transformation of the sarcous element of the muscle into fat, and was in no sense a deposit or infiltration. Whether the granules remained as such, or coalesce to form globules, the condition was the same. The difference was in degree, but not in kind.

Dr. Peabody admitted that the term was a loose one, and did not explain the pathological condition. He was aware that fatty degeneration was a transformation of the sarcous element.

Dr. Heineman referred to the teaching of Prof. Clark in regard to the difference between fatty degeneration and fatty infiltration. The former was a transformation of the sarcous element, and the latter was a deposition of fat beneath the sarcolemma.

Dr. Peabody presented a second specimen, which consisted of a heart of normal size removed from the body of a man thirty-five years of age. The patient was admitted to the New York Hospital during the summer, and died from sunstroke a few hours after admission. At the post-mortem examination there were found the usual lesions of the disease, and in addition an interesting and anomalous condition of the aortic valve. There were but two cusps to the valve, one of them being twice the size of the other, and no evidences of previous inflammatory action to account for it. Dr. Peabody believed that the condition was one of congenital malformation, and stated that he had failed, in a hasty reference to the literature of the subject, to find any case like it.

TUBERCULAR MENINGITIS, WITH EXTERNAL AND INTERNAL HYDROCEPHALUS.

Dr. Robinson presented a specimen of dilatation of lateral ventricle on behalf of a candidate for admission to the Society, after which he exhibited a brain which illustrated the lesions of tubercular meningitis with external and internal hydrocephalus. The history of the case, from the hospital records, was as follows :

Edward Person, born in New York, aged thirty-seven, married, no occupation. Admitted to St. Luke's Hospital September 17th. He was brought into the hospital completely unconscious, and the following incomplete history was obtained from his friends : Had been intemperate for several years (principally drinking beer). Two weeks ago was taken with a diarrhœa which was quite severe, but for the past few days it was pretty well under control. For the week previous has been more or less "out of his head" at various intervals. Yesterday morning (16th inst.) was perfectly sane, and went out alone for a walk, and drank some beer. Last evening became unconscious and has continued so up to present time. He lies quietly on his back, moaning with each expiration. Has nystagmus. Moves arms aimlessly about (right more than left). Incontinence of urine and fæces. Keeps his mouth open, and is almost incessantly moving lower jaw with a sort of lateral, grinding motion. Examination of urine: specific gravity, 1028, alkaline, muddy, with flocculi of mucus; no pus, no albumen.

9 P.M.—Patient much the same condition. Respiration, 40; pulse, 100; temperature, 101°. Pupils somewhat dilated.

September 18th, 9 A.M.—Respiration, 45. Patient is perspiring very freely.

3 P.M.—Examined by Dr. Robinson: Congestion of both lungs and pleuropneumonia of right lung, posterior. Doctor thinks this is an effusion into the right ventricle, and probably some meningitis.

September 18th.—Temperature, 9 A.M., 102⅗°; 9 P.M., 103⅕°. Pulse, 9 A.M., 120; 9 P.M., 146.

September 19th.—Has convulsive twitchings of muscles of left side of face. Respiration, 50. Same general condition. Temperature, 9 A.M., 104⅓°; 9 P.M., 104°. Pulse, 9 A.M., 145; 9 P.M., 142.

September 20th.—Patient failing rapidly. Temperature, 9 A.M. (axilla), 104⅓°; pulse, 9 A.M., 160, and dichrotic. Patient perspires freely. White film over left eye. 3.30 P.M.—Patient died, still having high temperature and sweating.

Autopsy, September 21st, 9 A.M.—Drs. Satterthwaite and Robinson present. Surface of brain œdematous, and considerable opalinity of pia mater. Congestion, thickening, and tubercular deposit (probably) of membrane along fissures of Sylvius of both hemispheres. In the middle of left optic thalamus a cheesy nodule, size of a walnut. Brain-tissue soft and watery. Foramen of Monro considerably dilated. Some effusion into ventricle of simple serous fluid (about four ounces).

Tubercular meningitis, with external and internal hydrocephalus. Left lung bound by adhesion at apex and upper lobe, posterior. Cavity, size of small hen's egg, in the anterior portion of upper lobe, which was empty and partially healed over. Also some tubercular deposit of this lobe and congestion of the lower. Right lung closely bound by adhesions throughout. Tubercular and pneumonic deposit scattered throughout the entire lung.

Tubercular phthisis and hypostatic pneumonia. Liver fatty, weight 3 lbs. 13 oz. Heart valves slightly thickened, weight 9½ oz. Kidneys slightly fatty; right, 6½ oz.; left, 6 oz. Spleen, weight 6½ oz.

FLUID FROM SPINA BIFIDA.

Dr. Louis H. Sayre presented some fluid which had been removed by aspiration from a case of spina bifida. The patient was a girl eight years of age, of perfectly healthy parentage. At birth there appeared a small ecchymotic spot in the lumbar region, which gradually enlarged until it attained the size of a large orange. The case was seen by Dr. Sayre, senior, who encased the swelling in plaster to guard against any injury to the part. The only symptom complained of by the patient was severe headache when any undue pressure was made upon the swelling. After repeating the applications of the plaster as occasion required, aspiration of the sac was finally determined upon and performed. After six ounces of fluid were withdrawn, a drainage-tube was inserted. The patient suffered from no inconvenience during the operation. Dr. S. stated that the patient would suffer from nausea and vertigo on rising in the morning.

Dr. Amidon thought that these symptoms were occasioned by a relative change in the pressure of the cerebro-spinal fluid as a result of gravitation.

Dr. Heitzmann next presented some reasons why there should be a change in the nomenclature of sarcomatous tumors.

ON MYELOMA (VIRCHOW'S SARCOMA).

He claimed that Virchow's terminology was incorrect, both because the word sarcoma had no significance, and these tumors, as all others, were built up by a tissue, and not by individual cells. On closer examination it had been found that all medullary elements were connected with each other by means of delicate offshoots of living matter, which pierced the surrounding narrow basis- or cement-substance. A reticulum of living matter was present, also, in every variety of fibrous or myxomatous basis-substance. He proposed the term "myeloma," which first had been suggested to him by Dr. L. Elsberg. Essentially, there are but two varieties, viz.: globo-myeloma and spindle-myeloma (Virchow's round-cell and spindle-cell sarcoma). Net-cell sarcoma was nothing but a spindle-myeloma, in which the spindles produce a relatively wide reticulum. Virchow's giant-cell sarcoma did not represent a special variety, but was a myeloma with multinuclear protoplasmic bodies, which only indicated the tendency toward the formation of a basis-substance. Also melanotic and alveolar myeloma were only sub-varieties. Myeloma represented the most primitive, embryonal, medullary tissue, and also clinically, the most malignant type of tumors. Cancer, when growing rapidly, often changes its structure into the more simple structure of myeloma.

Dr. Satterthwaite believed that it would be desirable to change the nomenclature of tumors, but that it would be immature to do it at present, in view of the accepted working model of Virchow.

Dr. Peabody stated that such a change was a serious undertaking in the face of the general acceptance of Virchow's classification. In any event, he thought that great care should be exercised to prevent the combination in one term of words derived from different languages.

The Society then adjourned.

* * *

Experience with Eight Hundred Obstetrical Cases.—Dr. W. J. Kelly gives a summary (*Ohio Medical Recorder*) of 800 obstetrical cases, and appends to his analyses some very sensible conclusions from his experience.

The forceps he commends very temperately; he prefers the long forceps of Hodge. For rigidity of the os uteri he strongly recommends warm baths or tincture of lobelia in doses sufficient to produce nausea. Ergot he condemns as a very dangerous drug, which he has used with more caution every year. Following the administration of chloroform, he has always found more danger from post-partum hemorrhage, and its use during application of forceps is unqualifiedly condemned. Version has been the trial of his life, and is never resorted to when it can be avoided. In puerperal fever, veratrum viride and quinine have always acted well. In placenta previa his practice always has been to divide the placenta with the fingers, rupture the membranes, and allow the head to descend. In this way hemorrhage has always ceased, and labor progressed favorably.

Correspondence.

INDUCED HYSTERICAL SONAMBULISM AND CATALEPSY.

Muscular Hyperexcitability—Induced Delusions and Aphasia—Phenomenon of Suggestion—Universal Muscular Contracture—Method of inducing these Conditions.

To the Editor of The Medical Record.

Dear Sir :—About the court-yards and the wards of Salpêtrière, pursuing various occupations, such as reading, sewing, and assisting here and there, one may see any day a goodly number of patients, whose appearance is far from suggesting that they are the subjects of the violent convulsive attacks incident to hystero-epilepsy. Unlike the epileptics—the class that would most nearly correspond in respect to this apparently normal interval—these patients present no sign of intellectual dulness. The hystero-epileptic is bright-witted and vivacious ; the epileptic dull-witted and listless. But a day later we may see any one of these intelligent and seemingly healthy young women launched into a long series of violent crises, such as described in my last letter. Having then fully considered the "attack," we may now at leisure give our attention to the behavior of these same patients at other times.

In the first place, their condition in the intervals between the attacks is by no means as normal as it appears. To say nothing of that emotional instability (disposition to laugh and cry, etc.) so characteristic of the hysterical, there will be found, on examination, certain tolerably permanent physical changes relating to the general sensibility, the special senses, and the muscular sense and force ; indeed it would be safe to say changes relating to the whole innervation of given districts—in most instances an entire lateral half of the body. For instance, all of these patients will be found to be hemianæsthetic, generally on the left side ; pinching, cutting, or burning produce no sensation of pain, nor do tests of temperature, position, etc., provoke their normal responses ; in short, the cutaneous anæsthesia is absolute ; they are equally hemiparetic, or, to use a milder term perhaps, hemiamyosthenic ; tested by the dynamometer their muscular power is found to be weakened on one side or the other. If the examination is pushed farther, the hemianæsthesia will be found also to involve the mucous membrane and the special senses—all this on the same side of the body. The hearing is dull ; the eye is amblyopic, and fails to distinguish, perhaps, any color whatever, or, if the entire field of vision is not achromatopsic, distinguishes the red or the yellow ; and the sense of smell and of taste are also abolished.

The only exception to this almost absolute obnubilation of nerve-function upon one side is the existence of a certain number of hyperæsthetic and at the same time hysterogenetic points or regions. At these points the cutaneous anæsthesia is as complete as elsewhere, thus presenting a ready means of diagnosis from dermalgia, in which the cutaneous sensibility is exaggerated to such a degree that a slight touch even may produce intense pain. The hysterogenetic regions, on the contrary, are more deeply situated, and are characterized by the peculiarity that slight pressure upon them, or other form of light irritation, will produce the complete hystero-epileptic seizure, or at least certain auræ, while strong and continuous pressure will produce an arrest of the seizure, however originating. This, contradictory as it seems, has been demonstrated again and again, until, by mere force of repetition, it has become an acknowledged law. Chief among the hysterogenetic zones is the ovary.

But all the symptoms just alluded to may be taken up more suitably in connection with the effects produced by magnets, metals, and static electricity. They have been mentioned here only, since they take a natural precedence of the more novel symptoms whose description follows, viz., induced hysterical sonambulism and catalepsy.

One morning Prof. Charcot very kindly had a number of these hystero-epileptic young women summoned, and demonstrated, as he has already done hundreds of times on numbers of different patients, certain phenomena, which I will attempt to describe as they occurred, always asking my readers to remember that I have no other office, for the present at least, than that of a simple mirror, which reflects to their eyes the morning clinic at Salpêtrière.

In approaching the subjects of induced hysterical sonambulism and catalepsy from a scientifically medical point of view, I cannot forbear quoting some very pertinent words of Doctor Paul Richer, formerly interne at Salpêtrière, in regard to the spirit in which the work has been prosecuted. "Despite the difficulties of all sorts," writes Dr. Richer, "which such a subject must, in the nature of things, present, M. Charcot has not hesitated to begin this study ; for he thinks that all natural phenomena, whatever may be their appearance of complication or of mystery, are none the less susceptible of methodical examination, and that it is the part of a true observer to guard himself, as well from denials easy to make from the standpoint of having prejudged a case, as from the danger of giving too free rein to the imagination. It is no more allowable to deny facts rigorously observed than it is to rest upon a single incomplete observation theories which, at the least, are premature."

1. Sonambulism and Induced Delusions.

The first patient brought into the clinic was Witt——, a young woman of about twenty years of age, large, finely formed and muscular, and suggesting, in personal appearance, no idea that she differed from healthy people. Her hereditary antecedents, however, from a neuropathic point of view, were bad ; her father had been insane and her mother "nervous." Hystero-epileptic attacks began at the age of fifteen, but were not very frequent. At eighteen they became frequent, and the *series* longer, and she was admitted to Salpêtrière. Her case is a perfectly typical one. All the familiar symptoms may be studied in it : hemianæsthesia, hemiparesis, ovarian hyperæsthesia, hysterogenetic zones, achromatopsia, etc. She had been summoned, on this occasion, for the examination of two additional symptoms—sonambulism and catalepsy.

Having first established the fact, by indiscriminately thrusting large needles through her skin, that a complete hemianæsthesia existed on the left side, Prof. Charcot asked her to be seated, and to look at his finger, held a few inches above and in front of her eyes. Her look remained fixed upon the finger for perhaps ten seconds, and then all at once her head fell heavily to one side, her eyes closed, there was a slight sound and movement of deglutition, and the patient slept. Her body was in a state of complete resolution; if an arm was raised by the observer, it fell again heavily.

The process just witnessed is most commonly known as hypnotism, the state as that of somniation, sonambulism, or, as proposed by Prof. Charcot, since it involves no theory, lethargy. The patient will remain in this condition of sonambulism (retaining for the present the more familiar term) for many hours, but may be aroused from it at any moment by blowing quickly in the face, when, upon awakening, she will be found to retain no recollection of anything which has occurred during her sleep. We may now note a most interesting phenomenon characteristic of this state; this, discovered by Prof. Charcot, has been named by him muscular hyperexcitability.

If, for example, we press lightly upon any muscle we choose to select, or, better still, rub it with moderate force, we shall at once produce in it a persistent contracture, and that to an extent of rigidity depending upon the degree to which we have excited it. Light pressure or rubbing produces slight contracture, strong pressure produces extreme contracture, and, as indicated by the word contracture, the muscular contraction produced is persistent. In order to undo or resolve this contracture it is necessary to rub, and thus excite, the antagonistic muscle until the member or trunk has resumed its natural position. The method of producing this contracture most nearly recalls that pursued in electrization at the usual electromotor points. But it does not appear that one need confine himself to these points.

Let us see how what we have just described applies to our patient, now asleep with head drooped, and reclining in the chair before us, a helpless subject for experimentation. The left sterno-cleido mastoid is rubbed several times with the point of the finger, and straightway this muscle stands out like a rigid column in the neck producing at the same moment its usual action of turning the face around to the right; we have a perfect torticollis which, left to itself, would persist at least for a number of days. But the opposite sterno-cleido-mastoid is now rubbed and contracts until the face looks directly forward, and the torticollis is resolved. The flexors of the forearm are pressed upon and rubbed, and they at once become rigid, flexing of course at the same time the hand upon the arm. If the irritation be continued the muscles become extremely hard, and the bystander, by any force which he can reasonably exert, cannot overcome this flexion. But it may be at any moment resolved by rubbing the corresponding extensors. Or a number of muscles may be contracted at once—the flexors of the forearm, and we have flexion at the wrist—the biceps, and the forearm flexes in the upper arm—the pectorales, and arm and shoulder draw inward and forward, recalling in features the contracture seen in hemiplegia. But all this may be resolved at once, if the bystander or operator chooses, by simply exciting in turn the natural antagonistic muscles.

In short, it was perfectly evident that each muscle in the body could be made to exert and maintain its normal action. This was the more patent when demonstrated upon small and isolated muscles. Taking for convenience a penholder, its blunt end was pressed upon the attollens auriculæ, at once the ear was elevated; or upon the retrahens, and the ear moved correspondingly. I satisfied myself of this again and again, not only in the case of Witt——, but in that of several others, by selecting isolated muscles with special actions, generally taking the familiar electro-motor points for the experiment. Pressure upon the pronator longus, and pronation alone ensued—upon the supinator, and supination resulted; or, for variety, upon the two extensors of the thumb, and each acted upon its proper phalanx. A most interesting demonstration was to select in turn, using the end of the penholder, the group of muscles about the thumb—nothing could be more exact than the results elicited—an opponens, an abductor, an adductor, a flexor, each in turn responding by throwing the thumb into corresponding positions, each of which positions persisted as a contracture until resolved by exciting an antagonistic muscle. In the same manner any single muscle of the face was made to contract. The experiment, of course, was susceptible of an endless variety of combinations. The very natural suggestion arises, may not the future anatomist, who writes upon the action of muscles, contribute much to scientific accuracy by studying from such a subject as Witt——?

But the same kind of contractions may also be brought about by exciting by pressure the trunks of nerves. Pressure upon the ulnar at the elbow produces a fixed state of contraction in all the muscles innervated by this nerve. If the facial nerve at its exit in front of the ear is pressed upon, the mouth and side of the face is drawn strongly to the corresponding side, though owing to some as yet unknown law of exception the contraction of the facial muscles remits as soon as the irritation is removed.

Up to this point it has been possible not only to produce a contracture, but to resolve it at will. —the patient, it must be recollected, being all this time in a state of sonambulism. But we may create a contracture which cannot be thus removed. We will suppose that, having produced a strong contracture of flexion at the wrist and at the elbow, one blows quickly in the face of the subject and wakes her up. She blinks her eyes, stares about her a few seconds to get her bearings, and then suddenly discovers that her arm is rigid; she tries in vain to move it; it seems as firm as metal, and thus it will remain for several days if left to itself. The physician cannot now, as previously, resolve this contracture by rubbing the antagonistic extensors. True, a very strong faradic current applied to the extensors will overcome the contracture, but the moment the current is remitted the arm flies back to its contractured state almost as if it were a steel spring put on the stretch and suddenly let loose. There is but one means of resolving this state of affairs, and that is to again put the patient to sleep; the contracture may then be made to yield on the instant to the usual process of exciting antagonistic muscles. The patient, for example, may be waked from her sonambulic sleep with an artificially produced torticollis. One may imagine how very puzzling this would be to a physician not knowing the history of the case. If we recall in this connection the fact that exactly these same contractures may occur spontaneously in the hysterical, we see at once the important bearings of these cases of artificially produced contracture.

I recall, for instance, in the case of an hysterical girl, a torticollis which was operated upon by tenotomy again and again by a distinguished surgeon, and treated by apparatus for months—all without the slightest curative effect. In another instance the tendo Achillis was cut more than once in the same kind of a patient, equally with no result. Such cases at least are suggestive.

The experiment of waking the patient with a contracture which neither she herself nor any one else can relieve (without again hypnotizing her), is of course, like the first series of experiments described, subject to many combinations. Some of the contractures thus produced and left to the patient may be ludicrous, and some more or less distressing and dangerous. Often the tongue is contractured by pressing the finger upon its base and thus rendered immovable; the patient is waked and finds herself speechless. Or again, in too much manipulation about the neck, muscles of the larynx become contractured, and a distressing and persisting laryngismus stridulus is produced.

Our patient, Witt——, has thus far been in the first stage only of the induced sleep—a stage most familiarly known as that in which the patient may wander about (whence the term sonambulism), answer questions, obey commands, etc. Up to this point we have examined only a single characteristic of this stage, viz., the muscular hyper-excitability, since this one point is not only a newly discovered one, but has also an extreme practical interest in its relations to every-day practice. We will pause for but a word in regard to induced hallucinations, another characteristic of this stage, and then pass on to the second, or cataleptic stage, where we may also pause by the way to observe induced aphasia.

Two simple experiments performed on another occasion with Witt—— illustrate the method of producing hallucinations. Witt—— is hypnotized; her eyes are opened by the operator, and she is told to look carefully at the bystander—that he is Ernestine, a young woman friend of hers present. Her eyes are then closed. Ernestine is now led up, Witt——'s eyes opened, and she is told several times that Ernestine is the bystander, and her eyes again closed. The operator now blows quickly upon W——'s face. She wakes, and at once addresses and treats the bystander as Ernestine, and Ernestine as the bystander. This delusion persists a long time unless W—— is again put to sleep and the hallucination removed by reversing the process of its creation.

Or again, W—— is hypnotized, her eyelids held open, and the operator directs her attention to a spectator upon whom he is pretending to greatly elongate the moustache, pull up the collar to a ridiculous height, form colored rings around the eyes, and otherwise figuratively represent him as ludicrous. These pantomimic motions ended, W——'s eyes are closed, and she is awakened. She takes a second or two to recover her wits, and then looks up. She catches sight of the spectator thus transformed to her eyes, breaks into laughter, and runs away, saying, "Oh! what a droll man," "Who is he?" etc. This impression will, as in all of these instances of provoked or induced hallucination and delusion, remain for all day, or perhaps several days, unless dissipated, as already described.

There is, of course, infinite variety to this experience. We have only to delineate to the eyes of the patient the crucifixion or the image of the Virgin Mary, and we shall have at once all the attitudes and expressions of veneration, love, worship, and beatitude, just as recounted in multitudes of histories where undoubtedly these hallucinations have occurred spontaneously, as they often do in this numerous class of excitable women.

II.—CATALEPSY AND INDUCED APHASIA.

Witt—— thus far then, as we have just said, has been in the first stage of the induced sleep, that of sonambulism. We recall that the trunk and members were in a state of resolution, and the eyes closed. She may now, in the simplest manner imaginable, be made a cataleptic, and thus enter a second stage, accompanied with new phenomena. The upper eyelids are raised by the operator, and it is done. A slight sound and movement of deglutition announces the transition, and perhaps a little foam in the corner of the mouth. There is now no isolated "muscular hyperexcitability." We press and rub the muscles in vain; there is no contraction or contracture. On the contrary, an altogether different condition exists: body and limbs now maintain any position in which they are placed; in short, we have the condition familiarly known as catalepsy. If the arm is raised to a right angle with the body, it remains so; if the leg is placed in a similar position, it does not fall. The patient may be moulded at will, like a waxen figure, into any pose one pleases, and the position will be retained. The patient is totally anæsthetic, whether so previously or not. She makes no response to questions, nor in any way gives any sign of being in communication with the external world; the eyes are wide open. There exists but one method of producing in her any external evidence of intellection. This constitutes the curious phenomenon called "suggestion." If, for instance, the now waxen limbs are placed in a pose which indicates aversion, *i.e.*, with the arms fully extended in front and the palms of the hands turned outward, the muscles of the face at once contract, and its whole expression is that of aversion. If, again, her hand is placed at the lips, as in the act of throwing a kiss, the face at once breaks into a smile.

The catalepsy may be equally simply resolved by closing the eyes. The arms, for instance, a second before raised and fixed like those of a statue in a given attitude, fall, at first slowly, then more quickly and heavily, downward. The whole body is now again in a state of resolution. We have returned from the stage of catalepsy to the first stage, that of sonambulism. Or, the experiment of transition may be varied in an interesting manner. The patient, we will say, is in the first stage, that of sonambulism. We open the right eye, and she is now cataleptic on the right side, for the limbs of this side will preserve any attitude given to them, while the muscular hyperexcitability has disappeared; at the same time, on the left side, the muscles are still in the condition appertaining to sonambulism, *i.e.*, hyperæsthetic, for the usual contractures may be brought about in any of the single muscles of that side. If now the left eye is opened, the patient becomes wholly cataleptic; if both eyes are closed, she is wholly sonambulic.

We have here the curious anomaly of hemi-catalepsy and hemi-sonambulism existing at the same moment in the same patient, and occupying indifferently, though each in turn, the one side or the other of the patient's body, according to the will of the operator.

We will at this point relate a most interesting experiment, that of induced aphasia (*aphasie provoquée*). Witt—— is in the state of sonambulism. We ask her to count. She begins, and pronounces in a monotonous manner, one, two, three, four, five, six. We open the *right* eye, and still she continues, seven, eight, nine, ten. At this moment we open the *left* eye, and she has on the instant ceased. We close the left, and she continues, eleven, twelve, thirteen. We open it, and she ceases. This is to say, opening the right eye has no effect upon language, while opening the left eye has obliterated it. We may repeat this experiment in many ways, and on many patients, always with the same result. She may be asked to repeat a verse familiar to her. The right eye is opened, and she still continues; the left is opened, and she stops short in the very midst of a word. When the left is closed she finishes this word and continues the verse, unless again interrupted. Or she may be asked to write a verse. The left eye is opened, and the pen pauses on the stroke of a letter; it is closed, and she continues. Opening the right eye has no effect upon her progress.

This is a striking corroboration of the theory that language resides in the left hemisphere, and it is interesting to know that it was communicated by Prof. Charcot to Prof. Broca some months before his death.

At this point we may leave Witt——. Her case is a very typical one, but there are others at Saltpêtrière in which the same phenomena may be equally well studied, some exhibiting one stage, some another, in different degrees of perfection. Now and then unusual and exceptional symptoms are presented, as in the following instance of an interesting young girl named F——. Meeting her at any turn of the wards or corridors, Prof. Charcot says: "Look at me a moment, F——." She obeys, and after about five seconds of intent gaze on her part falls slowly backward in a state of universal muscular contracture, in the form of opisthotonos. She is at the same time totally anæsthetic and insensible to all external surroundings. At the end of several hours she returns to consciousness and muscular flexibility. No means of arousing her have yet been found. Prof. Charcot regards this as a third stage of that general condition of which sonambulism and catalepsy form an allied part.

And now a few words as to the methods employed to bring about sonambulism and catalepsy. That most commonly in use is by the simple process of holding the finger, or, if preferred, a bright object near to and just above the eyes. This produces the first stage, or that of sonambulism. Another method is to place the patient in front of and facing a brilliant light—an electric or Drummond lamp—and cause her to look intently at it. In a few seconds, or perhaps a few minutes, the cataleptic state supervenes. By closing the eyes the patient then becomes sonambulic and vice versa. Or the cataleptic state in many patients may be instantly induced by the "sonorous vibrations" of a large tuning-fork, or by the loud sound from a Chinese gong struck unexpectedly. In fact, those subjected to these experiments seem soon to become so susceptible to any method that they fall at once into one stage or the other upon very slight provocation. With many indeed it is sufficient for the physician merely to close their eyelids suddenly while he is speaking to them, and they are at once sonambulic, and may then, as described, be made cataleptic.

In bringing about this sleep the personality of the operator is altogether unimportant. Prof. Charcot often turns to a visitor or a student and requests him to make the experiment, and in all instances the result is the same. Nor are any manipulations or passes made use of; they are unessential. It is perfectly understood and accepted that these phenomena are entirely subjective. The vagaries of animal magnetism, using the term in the sense that any influence passes from the operator to the subject, find no support at Saltpêtrière. Professor Charcot offers no explanations; he says simply, "facts first, theories afterward." But we may now see, from what has preceded in this letter as well as in others, that the study of sonambulism and catalepsy has been the very natural outgrowth of investigations into the nature of hystero-epilepsy, or we should now say with increased confidence, of hysteria major, for both of these conditions frequently occur spontaneously in hystero-epileptics, not only during the apparently normal interval between series of attacks, but also during the attacks themselves, replacing in the latter instance one or another of the well-known periods. The two directions of study then—sonambulism, catalepsy and allied states on the one hand and hysteria major on the other—form a very natural supplement and complement.

But I have already passed beyond the limits of a single letter. My only apology is that it has seemed to me that the readers of the RECORD will be equally interested with me in seeing these matters studied from a practical rather than a visionary standpoint; for these subjects are left too much in the hands of mediums, clairvoyants and charlatans, who, getting hold of a single available and apparently supernatural phenomena, play upon the wonder of the multitude. Or what is sadder still, such phenomena, having become in themselves a matter of repeated observation, and therefore facts, to the trained physician, are used by him as a basis upon which to erect theories of "magnetic influence," "influence of mind on matter," "mind reading," etc., etc., until, as a result, he himself and his readers are led off into the quagmires of the unknown. Be it the charlatan or be it the visionary scientist whom the community has followed beyond its depth, at last comes the opposite swing of the pendulum, and facts become now as much underrated as before overrated. More or less sceptical or more or less speculative seems to be the present state of the medical world's mind in regard to the phenomena described briefly in this letter. Of the measure of the former I will not speak—of the measure of the latter just a word of quotation from a recent medical work of apparently good authority will bear witness.

"Magnetism is the special action that the nervous activity of a person in health, and endowed with a *power* which, in want of a better term, we shall call magnetic, exercises on the nervous activity of another;" or again, "according to the law of influence the nervous activity of the operator vibrates in unison with that of the subject," etc. Here we have the speculative side of the question. But we have neither time nor space to criticise such views. We merely hold them up for contrast. On the one hand a "power" or influence residing in the operator or "magnetizer," and passing through intervening space to the subject; on the other the recognition of the fact that all the phenomena in question are subjective; that they reside in the personality of the patient, and may be excited into activity by a dozen and one methods, or, indeed, occur spontaneously; the recognition of the fact, in short, that we have to deal simply with the symptoms of disease. From this latter point of view the magnetizer, with his passes and counterpasses, his manipulations and his concentration of mind, his "nervous activity" and his special power, retreats into the mists of superstition, while at the same moment the physician steps forth into a field of investigation strictly within the domain of scientific medical study. Such, at least, are some of the reflections suggested by our morning clinic at Saltpêtrière, and inspired also, I may add, with equal ability on our own side of the Atlantic.

Very truly yours,
WILLIAM J. MORTON, M.D.

PARIS, August 20, 1880.

MEDICAL REGISTRATION LAW.

To the Editor of The Medical Record.

Sir:—A leading article in The Record, of October 9th, referring to the Medical Registration Law, observes that "the countersigning of diplomas that are granted outside the state does not appear to be very well understood." With this observation every one who has striven to elicit a consistent meaning from the clumsy phraseology of the Act in question must fully concur, and I crave tolerance for my presumption in doubting whether your editorial explanation satisfactorily solves the difficulty.

If section 4 stood by itself, the present participle, "coming," might, perhaps, be construed as implying a future sense; though, even so, it would be questionable if a person who came into this state on the 30th of September (*i.e.*, "before the 1st of October") could register an unendorsed foreign diploma.

But section 6 renews and aggravates the confusion of past, present, and paulo-past-future, and unsettles all the ideas which one may have laboriously derived from the preceding sections. "Nothing in this act"—that is, neither requirement of registration nor of endorsement of diploma—"shall apply to commissioned medical officers of the United States army or navy, or of the United States marine hospital service. Nor shall it" (presumably anything in this act) "apply to any person who has practised medicine and surgery for ten years last past, and" (mark the "and") "who is now pursuing the study of medicine and surgery in any legally incorporated medical college within this state, and who shall graduate from" (from whence is not mentioned) "and receive a diploma within two years from the passage of this act." If the peculiar syntax of this clause bear any meaning at all, it means that ten years of practice confer no immunity unless the practitioner be "now" (*i.e.*, at the date of the passage of the act) studying his profession in an incorporated medical college. It seems, also, to mean that if any person have seen fit to practise medicine and surgery for ten years before beginning to study, the question of his registration is to be deferred until two years shall have determined his possible fitness to "graduate from and receive a diploma." Setting aside grammar, however—as the originator of the act has manifestly done—it appears probable that the spirit of section 6 was intended to apply only to the endorsement of foreign diplomas, leaving registration as compulsory upon all practitioners; and from this point of view present matriculation in a state college is required to entitle a physician of ten years' practice to register a diploma from another state without paying twenty dollars to the dean of some domestic faculty for an endorsement. What would be the judicial construction of the amazing muddle of language contained in this act is beyond guessing; indeed, a legal friend, after much puzzling over its ambiguity, recently told me that he doubted f any judge living would attempt to interpret such an incongruous document.

Nevertheless, whilst waiting for either a judicial construction or a judicial giving up of the conundrum, it is, as you remark, desirable that our profesion should show its willingness to comply with any measure intended to elevate the status of medicine; and to the end of securing unanimity of action in this respect some discussion is needed. If, as you opine, "every man who came into the state before the 1st of October, with a diploma from outside the state," is entitled to registration without further inquiry, why is there the subsequent provision of a ten years' limitation? Suppose the case of a man who has been practising for some time here on the strength of a "single qualification" license from a minor British provincial school: is he authorized to register his inferior grade as a full and sufficient guaranty of his capability; or must his license be converted into a degree of M.D. by some home faculty? In other words, are our registration clerks to recognize the L.S.A., L.K.Q.C.P., etc., or does the act, in specifying (section 5) that "the degree of doctor of medicine, lawfully conferred by any incorporated medical college or university in this state, shall be a license to practise medicine and surgery within the state," exclude by implication degrees conferred outside of this state? In considering these questions it should be borne in mind that degrees from other states have never conveyed a legal right to practise here, each state alone conceding the title to practise within its own boundaries. Hence, the most rigorous construction of the "endorsement" clause would trench upon no vested rights, but solely upon the long-usual courtesy which it is to be regretted that the act did not explicitly extend to reputable schools elsewhere.

I am, sir, yours, etc.,

Alfred L. Carroll.

October 12, 1880.

[The questions raised in this communication have been referred to the chairman of the committee that had the matter of the passage of the act in hand. His reply is given below.—Ed.]

Interpretation of the Medical Act.

To the Editor of The Medical Record.

Sir:—It appears to the undersigned that most of the misapprehensions concerning the meaning of the act in question have arisen either from careless reading of the act itself, or from unacquaintance with previous acts undisturbed and unrepealed by this one. I will, therefore, with your permission, state briefly the force and intent of the different sections so far as I had any influence in their construction.

Sec. I. No question, I believe, has ever been raised as to the meaning of this section.

Sec. II. Declares that all persons legally practising at the time of the passage of the act (or rather twenty days thereafter*) shall register, etc. It has been asked who were legally practising at that time, and hence entitled and obliged to register. I can only reply by quoting the words of the last previous medical act, that of April 11, 1874, which admits to practice those "authorized to do so by a license or diploma from some chartered school, state board of medical examiners, or medical society." This, I conceive, includes the lawful holders of diplomas or authorizations to practise, from other states and foreign countries, who were, at the time the act went into effect (twenty days after its passage, which was May 29, 1880), practising in the state.

The word "coming" in the fourth section *is* to be taken in a *future* sense, and certainly does not apply to the persons just mentioned, who had already come and were engaged in practice. These persons were already licensed practitioners by the Act of 1874.

---

* Unless otherwise specified, a statute of this state does not go into effect until twenty days after its passage.

Coming now to section 6, it certainly seems to me that its meaning is sufficiently clear down *to* the words "nor shall it." I quote this portion: "Nothing in this act shall apply to commissioned medical officers of the United States Army, Navy, or of the United States Marine Hospital Service." I cannot imagine any other meaning than that the state did not wish to interfere in any way whatever with the medical officers commissioned by the general government. Section 6, as presented to the legislature by the committee of the State Society, terminated at the word last quoted ("service"). It so passed the Assembly. It so stood when the State Society's committee were given a hearing on the bill by the Senate Committee on Public Health, May 12, 1880.

Later, I received from Albany a letter dated May 26th, and containing the following: "Our bill passed the Senate with an amendment exempting persons who had practised ten years. It was not as I desired it should be, but thought we had better take it than nothing. . . . . The amendment was the work of ——— ——— ———."*

The amendment referred to reads as follows: "Nor shall it apply to any person who has practised medicine and surgery for ten years last past, and who is now pursuing the study of medicine and surgery in any legally incorporated medical college within this state, and who shall graduate from and receive a diploma within two years from the passage of this Act."

My first knowledge of the details of this amendment was when I read it in the certified copy of the act received from the Secretary of State a few days after its passage. Not being in the counsels of the person that procured this amendment, I am not prepared to offer any authoritative interpretation of what it was *intended*† to mean. Your correspondent and others may do as I have done—guess at it. My own surmise is, that the amendment was intended to exempt from registration and prosecution for practice for two years, those persons who, for ten years, had practised without legal qualifications, and who, at the time the act went into force,‡ were already matriculants in a medical college in this state. A larger number of persons, I conceive, however, could have availed themselves of this amendment if they had so chosen. For instance—both your correspondent and myself. If, for any reason, we desired not to register (at a cost of fifty cents), we could have matriculated (cost five dollars) at a medical college within the proper time.‡ Practically, however, I do not believe that a dozen unqualified practitioners in this state were in a position to avail themselves of this exemption clause. The great majority of such persons were not matriculants in a medical college at the time.§

I cannot follow your correspondent into the intricacies and "confusion of past, present, and paulo-past-future" of medical legislation in this state. The "past" he can acquaint himself with by perusing the compilation of the medical acts of the state since 1806, recently published by the State Medical Society; the "present" we have vividly before us; the "paulo-past-future" I shall not attempt to speculate on.

In the latter portion of his communication your correspondent raises some important questions. Before considering them, however, it should be understood (1) that the Act does not make a legal practitioner of any one who was an illegal practitioner at the time the Act went into effect, except such as are exempt by the latter portion of section 6; (2) that no one legally practising at that time becomes an illegal practitioner, except such as fail to comply with section 2 of the Act; (3) the county clerks, for obvious reasons, are not made the judges of who are and who are not legal practitioners; (4) the admission of an unqualified practitioner to registry does not thereby necessarily make him a legal practitioner; (5) the county clerk, so far as he uses his discretion in permitting and not permitting persons to register, must do so in accordance with the provisions of this Act, taken together with those of the Act of 1874; (6) the Act of 1880 was not intended to disturb the status of any legal practitioners, nor does it do so except in so far as it obliges them to register if they wish to continue to be legal practitioners.

Your correspondent alludes to foreign minor degrees and asks "are our registration clerks to recognize the L.S.A., L.K.Q.C.P., etc., or does the Act, in specifying (section 5) that 'the degree of doctor of medicine, lawfully conferred by any incorporated medical college or university in this state, shall be a license to practise medicine and surgery within the state,' exclude by implication degrees outside the state?" The law of 1874 made the diplomas of all medical colleges in the state licenses to practise, thereby repealing the provision in the Revised Statutes which declared that "the degree of doctor of medicine, conferred by any college in this state, shall not be a license to practise physic or surgery." The law of 1880 (section 1) confirms this portion of the Act of 1874, and provides (section 5) that this "shall be" the case in the future, or rather until the Legislature sees fit to change its mind on the subject. Section 5 excludes nothing. The other sections of the Act provide for that.

The minor degrees of foreign countries were not licenses to practise in this State prior to 1874. Whether they became such through this Act, thereby entitling the holder to registry, is a question that cannot be definitely answered except by a judicial opinion from the Court of Appeals. This has been an open question since 1874, which no one has yet thought it worth while to bring to a legal issue. At least, so far as I am aware, there has been no legal decision on the point. Certain it is, however, that the minor degrees referred to will not be licenses to practise in the hands of persons hereafter coming to this country.

Your correspondent regrets that the "long-usual courtesy" was not by the Act extended "to reputable schools elsewhere."

If he will take the trouble to prepare a clause satisfactory to the majority of the profession that will effectively exclude from this state bogus and low-grade diplomas, without at the same time interfering with the holders of diplomas from reputable colleges, and which clause would stand the ghost of a chance of becoming law, he will accomplish more, I am frank to confess, than the State Society's committee believed itself capable of doing. No one more than myself regrets the necessity for this seeming discourtesy to the reputable colleges referred to.

I remain yours, respectfully,

HENRY G. PIFFARD,

Chairman of the Committee on Legislation of the Medical Society of the State of New York.

OVARIAN TUMOR COMPLICATED WITH PREGNANCY.

SUCCESSFUL OPERATION.

To THE EDITOR OF THE MEDICAL RECORD.

SIR:—I was called, in consultation with Dr. Thos. Carson, June 20, 1880, to see Mrs. C. R——, æt. 28, married December, 1879, always had good health up to present illness, good family history. About February 1st she had ceased to menstruate; she thought she was pregnant, and although soon after this she began to fail in health, she did not call a physician until about April 1st. From this time until I saw her she had been confined to bed, had suffered but little pain, but was weak and had difficult breathing. At my visit I found patient with abdomen enormously swollen, very much prostrated, rapid pulse, breathing oppressed. After careful examination I made diagnosis of ovarian tumor, with pregnancy, which was concurred in by attending physician. I recommended that the tumor be aspirated, and that the pregnancy be left alone for the present, in the hope that abortion would occur before the tumor would again fill. This being agreed to, I aspirated the tumor, and withdrew thirty pounds fluid serum. The gravid uterus could then be distinctly felt, and there now seemed to me to be no doubt as to the correctness of the diagnosis. The operation was followed by great relief, and the patient improved in a general way every day. On July 1st miscarriage occurred, and a seemingly well-developed fœtus of five months was delivered, everything occurring in the natural way, and was followed by no bad symptoms. The tumor at once began to fill, and by July 30th was almost as large as at my first visit; she was suffering greatly from dyspnœa, rapid pulse, and fever. I again aspirated the tumor, but found the contents to be *pus*. I partly evacuated the tumor, withdrawing seventeen and a half pounds of pus, with but little relief to the patient. I then informed the patient that her only hope of life beyond a few weeks was to submit to an operation for the removal of the tumor, and the case would not admit of delay. After two weeks' deliberation she finally consented to have the operation performed. On the 16th of August I performed the operation, assisted by Dr. Thos. Carson, Dr. John Carson, Dr. W. T. Lannier, Dr. W. W. Leech, and Dr. W. W. Johnston. Her condition seemed to be almost hopeless; coated tongue; pulse, 120; temperature, 103.5°; extremely prostrated. It is not my intention to go into the full details of the operation, as they are in many respects familiar to all, but simply to refer to some of the more important points. The Lister spray was used, and full antiseptic precautions taken in detail. The tumor was multilocular, the larger cyst containing pus, the smaller ones serum (proving that even the *small* aspirating point may cause inflammation of the cyst-wall). The tumor was adherent to the omentum and to anterior surface of abdomen in several places quite firmly. The adhesions were all separated by the hand, except those of the omentum; that was ligated and cut, leaving ligature on omentum. The pedicle was ligated by double ligature, linked as suggested by Emmet. And now comes what I deem the most *important* part of the operation, the *thorough cleansing* of the abdominal cavity. *One hour* was spent in this; bleeding or oozing points upon the surface of the abdomen, that did not *entirely dry* by hot water and Monsel's sol., were carefully lifted by tenaculum, and a small ligature passed around and cut close; in this case *seven* points were so ligated. Sponges were used until they returned perfectly clean from all parts of the abdominal cavity. The abdominal wound was closed with silver sutures, and the surface of abdomen covered with salicylicated absorbent cotton, covered with oil-silk, and retained by adhesive plaster and bandage.

Not an untoward symptom occurred; she rallied from the operation well. Not a dose of anodyne, or *any other* medicine, was used after the operation. She was moderately nourished by beef-tea, etc., during the first week; solid food allowed after that. The external wound healed by first intention throughout, the high temperature and rapid pulse soon began to improve, and in two weeks were normal. At this date, October 7th, the patient is walking about.

J. L. CRAWFORD, M.D.

SALTSBURG, INDIANA CO., PA.

ERGOT-POISONING.

To THE EDITOR OF THE MEDICAL RECORD.

SIR:—In the number of THE MEDICAL RECORD of September 18, 1880, page 318, Dr. J. M. Keating, of Philadelphia, reports a case of ergot-poisoning, post-partum, in a woman who had previously suffered from some uterine troubles, ʒ ss. of fluid extract of ergot having been administered by the nurse every half hour "by misunderstanding," in anticipation of or to prevent returning uterine hemorrhage, following "ʒ ij. of the fluid extract administered by the doctor (who attended the delivery) himself," "after the uterus was well emptied, and the binder applied." After relating the symptoms of the patient, which he attributed to the action of the ergot, he says: "Upon inquiry I learned that in all she had taken about ℥ ss. of the fluid extract of ergot (and this was afterward corroborated by the medical attendant from the amount left in the bottle, which he himself had brought to the house)."

In the *Philadelphia Medical Times* for July 17, 1875, page 657, I reported a case of placenta prævia in which it is found I ordered "a teaspoonful of Squibb's fluid extract of ergot every half-hour," and by reference to that report it will be seen that the patient, up to, or previously to, the delivery, "had taken, in about twelve hours, an ounce and a half of fluid extract of ergot without injurious effects." It acted promptly and energetically in expelling the fœtus (one of six months) with the placenta, the latter first, with perfect safety, the case ending "without accident of any kind—with the loss of scarcely a drop of blood." "The powerful uterine contractions," "one of the most interesting features of the (Dr. K.'s) case," was also observed in mine; but what proved salutary in my case seemed to be detrimental in his.

My intention, therefore, is simply to call attention to another obstetrical case where ℥ iss. of Squibb's fluid extract of ergot was given, in about twelve hours, without detriment, "without injurious effects," and to show that, while there may be idiosyncrasies or conditions in which it may not be given with impunity, there may be other cases where it may be administered, not only safely, but with absolute benefit, even in largely repeated doses. In a large experience, I might say I have never seen a case of what might be termed real ergotism, or the toxic effects of the medicine, and I have used it freely and largely, not only in uterine, but in other affections; and may it not be suggested, that the "placental adhesions of great firmness, and, in consequence, more than ordinary amount of hemorrhage," in his case, were prominent factors in producing the symptoms, such as might occur from slight or temporary embolism, etc., and not the ergot. I say suggested, because I am attached to ergot, and do not like to abuse an old friend. S. J. Radcliffe, M.D.

THE "AMERICANIZED" METRIC SYSTEM.

To the Editor of The Medical Record.

Sir:—The advantages which would follow the use of the metric system have been proclaimed in nearly every city and town of the United States, and it is, therefore, unnecessary for me to present any arguments in its favor.

Most physicians appreciate these advantages, and a large number are using it in their prescription writing. A majority of the pharmacists have provided themselves with the necessary weights and measures, and are anxiously waiting the day when they can discard the time-honored drachm and ounce.

But, notwithstanding this gratifying appreciation, the system is not coming into use as rapidly as it should. In considering the subject, it has seemed to me that there are two reasons for it. 1. Many physicians, either through ignorance or prejudice, have not acquainted themselves with the system; and 2. Those who have acquainted themselves with it are afraid to prescribe by it, because they know their prescriptions might fall into the hands of a druggist who is not supplied with the metric weights and measures, and who is, moreover, ignorant of the rules for converting the metric to the Troy weight.

What, then, is necessary? Evidently some simplification and explanation of the terms used, and rules for conversion that are easily understood; so simple that one "running may read and be free from error." It is with this necessity in mind that I have arranged the following on the back of the ordinary prescription blank.

APOTHECARIES' AND METRIC WEIGHTS.

Equivalents—practical.

Troy Wt.	Grams.	Troy Wt.	Grams.
gr. 1—60	.001	grains 24	1.60
" 1—30	.002	" 30	2.00
" 1—20	.003	" 36	2.40
" 1—16	.004	" 40	2.66
" 1—12	.005	" 50	3.33
" 1—10	.006	" 60	4.00
" 1— 8	.008	drachms 2	8.00
" 1— 6	.011	" 3	12.00
" 1— 4	.016	" 6	24.00
" 1— 3	.022	ounce.. 1	32.00
" 1— 2	.033	ounces.. 2	64.00
gr. 1	.066	" 3	96.00
" 2	.13	" 4	128.00
" 3	.20	" 6	192.00
" 4	.26	" 9	288.00
" 5	.33	" 10	320.00
" 6	.40	" 12	384.00
" 8	.53	" 16	512.00
" 10	.66	....	....
" 12	.80	....	....
" 15	1.00	....	....
" 16	1.06	....	....
" 18	1.20	....	....
" 20	1.33	....	....

In order to simplify the Metric System, it has been thought best to have two units only, viz.:

The Gram, equivalent to fifteen grains or one-quarter drachm.

The Fluigram (or cubic centimetre), equivalent to fifteen minims, or one-quarter fluid drachm.

If the druggist has not the Metric Weights and Measures, he can easily convert the prescription (on the other side) into Troy weight, as follows: Multiply the figures on the right side of the vertical line by fifteen, and divide by one hundred, and the result will be grains. Divide the figures on the left side by four for drachms, and by thirty-two for ounces.

It will be noticed that there are several changes from the strict ruling of the metric system. First, and most important, is the substitution of the term fluigram for the cubic centimetre. This term was first brought to my notice by Professor Oscar Oldberg, in an article on The Pharmacopœia of 1880, Medical Record, August 14, 1880. He gives the credit of the suggestion of the term to Mr. Alfred B. Taylor. This term connects the unit of measure (the cubic centimetre) to the gram in the same manner that the old fluid drachm was connected to the drachm. It has been said by some, in objection to the new term, that it is carrying into the new system a fault of the old. This is not true, however, for although it is a fault in the old system to connect in nomenclature the drachm and fluid drachm, it ceases to be a fault when applied to the metric system, for in it the gram and cubic centimetre are the same—*practically*.

Again, it will be noticed that the gram is made equivalent to exactly fifteen grains. This is not exactly true in reality, for the gram is equal to 15.43234874 grains, but, if we are going to be accurate, we should have to consider these eight decimals. This would be almost impossible, certainly impracticable. If we are going to be practical, why not be really so, and make the standard for calculations a tangible number? Agreeable with this standard, we have 18 grains equal to 1.20 gram; 20 grains, 1.33 gram. At the time my blank was printed, I thought myself alone in making the gram equivalent to fifteen grains, but since then I have discovered that Prof. Oldberg has advocated it for several years.

Finally, it will be noticed that rules are given for the conversion of metric into Troy weight, and it may be well to explain them. All figures on the right of the line represent fractions of a gram; *e.g.*, take .20, it is $\frac{20}{100}$ of a gram, or $\frac{20}{100}$ of 15 grains=3 grains. The figures on the left represent entire grams, and should be divided by four for drachms and by thirty-two for ounces. A table of equivalents is added, which may be used to correct any mistakes in calculation. This table and rules remove, it seems to me, all objections ever urged against the metric system, and I hope it may play a small part in popularizing what should be *the* system of the world.

Geo. N. Kreider, A.B., M.D.

Springfield, Ill.

THE TREATMENT OF VOMITING OF PREGNANCY BY ETHER-SPRAY.

To the Editor of The Medical Record.

Sir—There is no disorder consequent upon pregnancy which so defies the skill of the physician, and which renders the patient more hopelessly miserable, than the one under consideration. I can conceive of no case in obstetrical practice which, when the patient is reduced to an alarming degree of exhaustion, is so thoroughly demoralizing to the young practitioner, who, perhaps, is inexperienced, and does not consider the grave moral responsibility attendant on abortion, and unwittingly yields to the solicitations of some of the household to the performance of the operation. Such a procedure not only destroys the life of the fœtus, but also jeopardizes the life of the mother. We apprehend that when it is a mere question of freeing the woman from the risk of a contingent, though not immediate danger, we are in no case justifiable in sacrificing the life of the child, and we must, therefore, under such circumstances, dissent from the conclusions of those who would sanction such a proceeding in any condition of the mother that does not indicate extreme peril. Now, I was placed in precisely this predicament, and, contrary to the wishes of the husband, refused consultation with a physician (?) who had asserted to some old women that, were he in attendance, he would certainly perform abortion.

The following case shows conclusively the propriety of judicious conservatism and the success of the treatment by ether-spray. Mrs. S——, aged thirty years, pluripara, two and a half months pregnant, had vomited almost incessantly from the first three weeks of her pregnancy. For four weeks she vomited every few minutes, and the smallest spoonful of fluid set up at once the most violent contraction of the stomach. In a word, the symptoms were so grave that I had almost decided that abortion was the only alternative left to me to prevent death from exhaustion. I now called in Dr. Porter (U. S. A.) for consultation, but as all the possible remedies had been tried without avail, further medication seemed entirely out of the question. I conceived, however, the idea that freezing the pneumogastric near its origin might possibly control the intensely irritable stomach, and suggested it to the doctor, who also reasoned that my theory was sound and logical, and in view of this fact we at once commenced the process of freezing the nerve in its track, under the sterno-mastoid, on both sides of the neck alternately. The effect was indeed remarkable, for decided benefit was observed after the first trial, and during the first twenty-four hours the woman vomited only four times, and in three days the vomiting ceased entirely. This process was performed every two hours the first day, and at much longer intervals during the second and third days, and continued ten minutes at each sitting—the pulse was closely observed.

The stomach, in sympathy with the pregnant uterus, becomes intolerant to both solids and fluids, and energetic contraction is set up when such are taken into it, a reflex phenomena produced in consequence of the intimate connection which exists between the uterus and nervous and digestive systems, a sympathy which a knowledge of the origin and distribution of the pneumogastric and sympathetic nerves would lead us to expect. As the muscular coat of the stomach is paralyzed by section of the pneumogastric, a similar, though less decided, effect may be produced by benumbing the nerve by the use of the ether-spray, and thus controlling the abnormal peristaltic action of that organ, hence controlling the vomiting. Again, it may be advanced that the sympathetic was in some way influenced by this freezing process, but as to that I am not prepared to say. As I have not met with any description of a similar method of treatment, or come in contact with any one who has employed it, I feel impelled to place it before the profession as a possible discovery in that department of medicine.

A **Loving-Cup** of solid silver, lined with gold, has been presented by Mr. Edwin Booth to Dr. Ghislani Durant, as a testimonial of his regard for the personal and professional attainments of the Doctor. The loving-cup, says a writer in *Harper's Weekly*, was first introduced by Margaret Atheling, wife of Malcolm Kenmore, in order to induce the Scotch to remain for grace. It was filled with the choicest wines, of which the guest was allowed to drink *ad libitum* after grace had been said. On the introduction of Christianity, the custom of wassailing was not abolished, but resumed a religious aspect. The monks called the wassail cup *poculum carita.* The term is still retained by the London Guilds, who use it in their meetings. In drinking from the loving-cup, two adjacent persons always stand up together, one to drink and the other to pledge his safety while so occupied.

A **Report on the Adulterations of Drugs** has been made to the National Board of Health by a Committee of the Philadelphia Drug Exchange. The report considers the propriety of legislation to prevent the adulteration of medicinal drugs, and it concludes that such legislation would be unwise, impracticable, and unnecessary. The actual amount of drug adulteration is believed to be small; and retail druggists and physicians are able to get pure drugs without difficulty, if they make the effort. Any legislative interference with the manufacture of the various preparations of drugs would be liable to do great injury to the manufacturers. The report and conclusions of the committee were adopted by the board of directors of the Philadelphia Drug Exchange. The report presents the matter in the best light for the Drug Exchange, but there is no doubt that its conclusions are essentially correct.

Bellevue Hospital Medical College.—The annual meeting of the Alumni Association of this College was held at Pinaud's, Monday evening, October 18, 1880, the President, Dr. A. A. Smith, in the Chair. The time for holding the annual meeting was changed to the evening of the yearly commencement exercises of the College. The following Alumni were elected officers for the ensuing year: J. Taber Johnson, of Washington, D. C., President; Laurence Johnson, of New York, and N. A. Ewing, Vice-Presidents; G. H. Swazey, Recording Secretary; Robert Newman, Corresponding Secretary; W. H. Katzenbach, Treasurer; F. A. Castle, Historian; G. W. Wells, member of the Executive Committee; Drs. T. H. Burchard and T. R. Pooley were appointed as a committee to escort the newly-elected officers to their seats. In absence of the President-elect, the Vice-President-elect took the Chair and thanked the Association, both for Dr. J. Taber Johnson and himself, for the honor conferred upon them. The retiring President, Dr. A. A. Smith, Professor of Materia Medica, Therapeutics, and Clinical Medicine in the College, then delivered the Annual Address, which was listened to with marked attention. The Association then adjourned to partake of a substantial repast. Within the last year Dr. Charles H. Sayre, of New York, and Dr. A. D. Felton, of Saratoga Springs, have been removed by death.

Answers to Correspondents.

Professional Competition.—Would you please to give the benefit of your valuable advice to our medical society upon the following: Our town has three thousand inhabitants and eight practitioners of medicine and surgery. Each doctor is the soul of honor, has a family diploma, a copy of the Code, and a secret longing for a specialty. Each one would like to announce his specialty; but that requires the renouncing of his general practice. After many warm debates we have become divided into two parties, and now we want you to bring about harmony by deciding which of these two is the best plan.

One party propose that we organize a medical college, each one taking a chair, which, of course, notifies the public what each man's specialty is, and yet allows of general practice, not to speak of the fees of the students or how much practice the title of "professor" might bring from a distance. I rather favor the idea. The other party oppose this (but they always oppose what we want); they want us to work under the law regulating the practice of medicine, which requires a diploma or a license from a county medical society. They say that each man could take ten students at two hundred dollars each, and after a year's study these students might come before us, we acting as a board of censors, and receive their license to practise by paying the same fee as they would for a diploma, which would be fair, as it amounts to the same thing. By this plan each man can examine in the specialty he wishes, and, of course, the public would soon find it out. I am well acquainted with the newspaper men, and our specialties would be advertised as well as by a professorship, and we make as much money.

I don't want to influence your decision; but, if you do decide for the college plan, don't you think it would have a good effect for us to insist upon the amended Hippocratic oath as used in Oregon, add to it the entire Code, and require each graduate to commit it to memory? You know that if the Code was taken away there would be nothing left of the practice of medicine.

The other party urge that as a society we have much more power than as a college, for a society can fix a fee-bill, and, by refusing or revoking a license to practise, dictate who shall practise, and in that way keep out competition. Yours anxiously,

Chloral Hydrate, M.D.

Since writing the above we have had another meeting, and it looks as if both plans would be put in operation. I am afraid there won't be students enough to go around.

Later.—More trouble! A strange doctor has located here with a microscope and a battery, and he has got all the preachers' families on his list. Of course there is no money in them, but think of their influence! I was appointed to inquire about his school. He said Darwinian; and when I wanted to see their code, he said it was too short to print—"The survival of the fittest." I don't understand him. We badly need his initiation fee and dues, so some of us think we had better compel him to join us according to law; but he has said that he could use his money and time to better advantage by buying and reading the Medical Record and other first-class journals, than to attend our medical caucuses; but, he said if we started a college, and did as they have done in Detroit—each professor publish his own medical journal—that he would subscribe. Why couldn't we? We are puzzled and divided about this fellow, as to whether we had better not compel him to join us and then revoke his license for "unprofessional conduct" (he took one of my patients away from me the other day without my written permission); besides, he says we are only a doctors' trades union, and the people are beginning to find us out. One-half of us are afraid we can't make him join us, and the other half are afraid he will yet insist upon joining.
C. H.

Rocky Mountain Medical Society,
Arapahoe Peak, Colorado, Oct. 1, 1880.

[There is, no doubt, room for a medical college in that locality, and each practitioner can select his specialty without overcrowding the faculty. What is left for general practice can then be handed over to any new comers. The microscope and battery be effectually disposed of by keeping them in the institution, as well as the man who knows how to use them. The faculty and county society can have the same members, one body endorsing the action of the other. Similar plans have worked well with other influential bodies having joint interests. If the college term is made short enough, and the fees proportionately low, there will be no difficulty in getting students. There will not be much danger of damaging competition by outsiders if the clinics of the college are kept in a flourishing condition, especially if the local papers show becoming enterprise. If promising young men settle in the place despite these drawbacks, it is just and proper to give them a chance to make their reputations by electing them clinical assistants. Should the worst come to the worst, each member of the faculty might publish a journal in his specialty and become a corresponding member of the Associated Press.—Ed.]

---

* The shape of this stone was that of a dumb-bell with unequal ends, the total length being 1¾ inch, the diameter of the broader end 1 inch, that of the narrow ½ inch, and that of the connecting length ⅜ inch.

† The operation was done for me by Dr. Brigstocke, M.R.C.S., London, during my absence from Beirût. I took the case in charge a few days after the operation.

‡ This calculus crumbled in the forceps, and half of it was lost with the gush of urine. Its weight should have been 1.50 grammes.

§ The reason for the choice of the lateral operation was a pseudo-anchylosis of the right hip which prevented the flexing of that thigh, and even greatly impeded the lateral operation on the left side. In this case there was no notable hemorrhage at the time of the operation, but serious secondary hemorrhage on the tenth day. It was controlled by the use of liquor ferri perchloridi, and the case made a favorable cure.

‖ The shape of this calculus, which was of very large size in comparison to its weight, was oblong and very irregular in shape. The impression given of considerable size in sounding led to the choice of the operation of lithotomy rather than lithotrity, which would have been preferable in this case.

¶ Operation done without anæsthetic. Much hemorrhage during and after operation, arrested by liquor ferri perchloridi. To make more effective pressure on the neck of the bladder and prostate, a sponge was introduced into the rectum and left there. Vomiting supervened on the operation and continued for twenty-six hours, apparently from the reflex irritation of the sponge, as it ceased on its removal, and the patient made a good rally. His strength, however, began gradually to give way, and he died on the sixth day of exhaustion. No coma until within seven hours of his death. No post-mortem was obtained

** In this case the father avers that the boy began to have symptoms of stone eight months previously, and that they then entirely disappeared for six months, when they reappeared and continued up to the date of the lithotomy.

†† Hemorrhage at time of operation trifling, and none externally after it. There was, however, bleeding from the neck of the bladder into the viscus for about eight hours after the operation, which was controlled by gm. 4 of tinct. ergot every hour. Since then no hemorrhage.

‡‡ At the age of seven years he was cut by a native charlatan, and a stone removed. He says that he has nevertheless had symptoms of stone ever since.

§§ The shape of this stone was oblong with one smaller end curled

II.—VESICAL STONES IN THE FEMALE.

No.	Name.	Age.	Residence.	Date.	Duration.	Operation.	No. of stones	Shape.	Weight, grams.	Analysis.	Results and remarks.
99	Mariam.	30	Jubail.	April 7, '77.	4 years.	Nicking of meatus and extraction.	1	Oval.	29	Phosphate and carbonate of lime.	Occurred after parturition. The stone presented at the meatus, and was removed by simply nicking the orifice and prying it out with the forefinger in the vagina. The incontinence caused by the long dilatation of the neck of the bladder, owing to the presence of the stone, was not relieved by the operation.
106	Femâmeh.	3	Mu'allakat ed Damûr.	Aug. 14, '77.	1 year.	Dilatation & extraction.	1	Oval.	1.5	Urates.	No incontinence from time of operation.
113	Milâdi.	11	Batroun.	Jan. 10, '78.	2½ months.	Dilatation & extraction.	1	Almond.	4	Phosphates.	Calculus broke down in the grasp of the forceps. No incontinence after operation.
137	Mudallaly.	55	Sadad.	July 2, '79.	From childhood.	Dilatation & extraction.	1	Oblong.	13.5	Phosphates.	Had no control over neck of bladder before operation. It gradually returned perfectly after the operation.

III.—CASES OF LITHOTRITY IN THE MALE.

No.	Name.	Age.	Residence.	Date.	Duration.	No. of sessions.	No. of stones	Weight, grams.	Analysis.	Results and remarks.
115	Saïd.	26	Beirût.	Mar. 2, '78	5 years.	1	1	1.5	Phosphates.	No febrile reaction. Aspirator not used.
134	Salim.	26	Damascus.	June 7, '79	5 months.	1	1	2	Urates.	Litholapaxy with Clover's aspirator. Most of the detritus removed by aspiration. One piece as large as a pea became subsequently impacted in the meatus and was removed by Civiale's urethral forceps. N.B.—Same individual as case 133 (urethral stones).
139	Sarufim.	65	Beirût.	Sept 2, '79.	2 years.	1	1	2	Phosphates.	Litholapaxy with Clover's aspirator. Sept. 24th a fragment was discovered and crushed, after which the symptoms disappeared.
147	Sarufim.	66	Beirût.	July 10, '80.	2 months.	2	1	0.50	Phosphates.	During the winter the patient had a cystitis, for which I treated him. During the treatment there were no evidences of stone. Two months since he began to have symptoms of stone. At the time of operation I attempted aspiration, but the bladder would not hold the water pumped in, which flowed out of the urethra by the side of the catheter as fast as introduced. The patient failed to collect the first fragments that passed, and thinks them more than he afterward saved. He left my care quite free from annoying vesical symptoms. The weight given is that of the fragments actually collected.

IV.—STONES PASSED PER URETHRAM IN THE MALE.

No.	Name.	Age.	Residence.	Date.	Duration.	No. of stones	Weight, grams.	Analysis.	Remarks.
107		25	Port Saïd.	Aug. 14, '77.	1 year.	1	0.4	Urates.	Pain continued a year in the region of left ureter, but after passage of stone the pain ceased. No recurrence of stone.
133	Salim.	26	Damascus.	May 31, '79.	30 days.	1	0.66	Phosphate of lime.	A year and a half ago he had pain in the lumbar region and penis, which lasted thirty days and terminated in the passage of a polished flat ovoid stone. See case 134, under lithotrity.
141	Neecash.	18	Beirût.	Sept., 1879.	6 days.	1	0.2	Phosphates.	Patient with rheumatic diathesis, enlarged heart with valvular lesions. Since the passage of the stone he has had no more symptoms in the regions either of the ureters or the bladder.

Notes continued from previous page.

upon itself. It was at first seized at its greater extremity, and in withdrawing it the projection caught at the neck of the bladder. It was afterward reseized and tilted up and so extracted entire.

§§ After complete reaction from the chloroform, hemorrhage set in. It was controlled by packing the wound with sponges saturated with liquor ferri perchloridi. These were removed fourteen hours after application. The febrile reaction was sharp, but not preceded by a chill. There was tenderness in the suprapubic region, and the urine was tinged with blood.

On the fourth day there was great tenesmus of the bladder and some hemorrhage. Small pieces of the sponge tampon passed per perineum. On the evening of this day four or five ounces of blood were lost. The flow was checked by the local native physician by simple pressure on the wound with a sponge. This practitioner considered it to be superficial, not from the neck of the bladder.

On the fifth day no hemorrhage.

On the sixth day, at 3 A.M., slight hemorrhage checked by sponge. A clot at the neck of the bladder caused retention and great pain. At 9 A.M. I drew the urine by a catheter passed through the wound, and then tied a No. 12 soft catheter in the bladder. No further hemorrhage occurred after this date, and the febrile symptoms gradually diminished under the use of quinine. The case was operated on in a somewhat inaccessible village, and I was not able to see the patient at critical moments.

‖ Two years previous to this operation he had had a stone crushed in Egypt, but the symptoms of vesical irritation had never disappeared. The two stones were probably formed about fragments left after the lithotrity. He was unwilling to have lithotrity done again.

The chloroform being given by an inexperienced person, respiration was quite suspended during the operation, but restored by artificial respiration repeated twenty-five times. There was considerable hemorrhage after the reaction from chloroform, but it was arrested by liquor ferri perchloridi. Death occurred on the fourth day with symptoms of uræmia. I may here remark that in an experience of several thousand cases of anæsthesia by *chloroform* I have never had a death, and only two or three times have had to resort to artificial respiration.

V.—Urethral Stones in the Male.

No.	Name.	Age.	Residence.	Date.	Duration.	Operation.	No. of stones	Shape.	Weight, grams.	Analysis.	Results.
120	Beshara el Khol.	5	Beirût.	June 15,'78.	3 years.*	Extraction from meatus.	1	Oval.	0.5	Phosphates.	Recovery.
126	Saad ed Din.	6	Beirût.	Oct. 22, '78.	1 year 6 months.	Extraction from meatus.	3	Oval.	0.5	Uric acid.	Recovery.
148	Sabbagha.	22	Beirût.	July 26, '80.	17 years.	†	5	Various.	32.5	... .	Recovery.

* Three years before a native quack incised the urethra one-half an inch behind the frænum and removed a small calculus, leaving a fistulous opening. The present operation consisted in crushing the stone with a director and prying the fragments out of the meatus, which was slightly nicked to admit of their more ready passage. The patient did not return, and I am, therefore, unable to report the ultimate fate of the fistula.

† The patient was operated on at the age of five years for a stone which he has not preserved. The operation seems to have been a modification of the Italian, consisting in cutting in the line of the raphe on the stone itself, which has been previously hooked forward on two fingers of the left hand introduced into the rectum and made to protrude in the perineum. This native operation is done without a staff. From the time of this first operation he has had perineal fistula and a stone in the scrotum.

The pathological phenomena were as follows: At the bottom of the scrotum, in the median line and pointing to the left side, was a hard tumor, about the size of a hen's egg, which imparted to the touch the sensation of the grating of stones on each other. There was a series of fistulous openings communicating with the sac in which the calculi were lodged. At a point three-fourths of an inch in front of the anus was another fistulous opening, as large as a goose-quill, extending obliquely forward and upward toward the membranous portion of the urethra. From this opening the young man had, from time to time, extracted small cylindrical calculi one-fifth of an inch in diameter and from one-half to an inch in length. One had been passed a few days before the operation.

The patient was placed in the lithotomy position, and the sac of the scrotal calculus laid open and connected with the anal fistula for one-third of its depth from the surface. Three stones were extracted from the scrotal sac, weighing in the aggregate, thirty one grams. Their adjacent surfaces were marked with perfect articulating facets. The posterior occupied the bulb of the urethra, and its posterior surface was in contact by a facet with the cylindrical stone occupying the posterior sinus. The scrotal sac was then dissected out, leaving sufficient mucous membrane to reconstitute the bulbous urethra. The sac was found continuous with an inch of this portion of the urethra. The posterior fistulous tube was then dissected out as far as the membranous portion of the urethra. The divided tissues of the bulb showed a tendency to bleed freely and no disposition to contract. Compressed sponge, moistened with liquor ferri perchloridi, was accurately applied to the bleeding surfaces, and a tampon of sponge with perineal pad and bandage completed the dressings. For two days the patient was unable to pass water, which was accordingly drawn by a catheter introduced through the meatus. After the separation of the sponge tampon he began to pass water by the perineal wounds.

On the twelfth day the last of the sponges were removed from the bulb. They were so adherent to the granulations as to require considerable traction for their removal. A part of the urine has began to flow by the urethra.

On the nineteenth day the wound was nearly healed. At times all the urine flowed through the urethra, at others through the sinus. The patient was directed to press the thighs together during micturition.

On the twenty-sixth day most of the water passed per urethra. Sinus only admits a fine probe.

EXPERIMENTS TO DETERMINE THE RELATIVE MERITS OF WATER AND AIR AS MEDIA OF TRANSMISSION FOR SPHYGMOGRAPHS.

By A. T. KEYT, M.D.,

CINCINNATI, OHIO.

The utility of the graphic method as applied to clinical and physiological investigations is being demonstrated more and more. The success is to be accredited in large part to the employment of the method of simultaneous inscriptions. The sphygmograph and cardiograph, used separately, give permanent records of the arterial and cardiac pulsations, and show some features of form not otherwise distinctly revealed; but these instruments, combined in one so as to trace the heart and an artery at the same time on the same side, afford additional important indications, and such as are unattainable by any other means. Thus, two (or more) properly constructed inscribing instruments arranged in this manner are capable of showing all the palpable movements of the organism in their individual forms and phases, and the relations of these movements to each other. The most valuable of Marey's contributions in this department are the facts he has been able to bring to light by the method of simultaneous inscriptions.

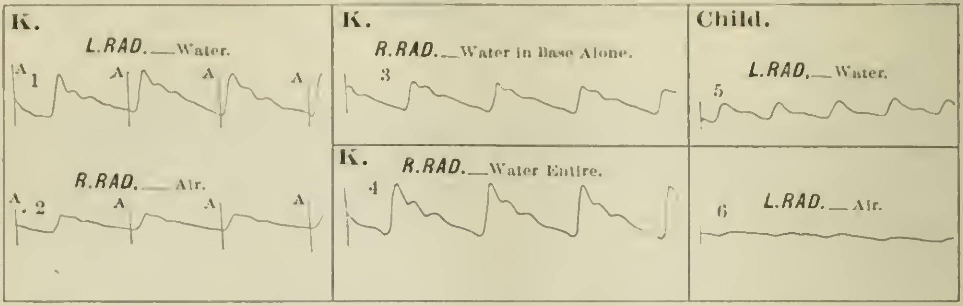
A direct sphygmograph, as Marey's, although tracing correctly the form of the pulse, is not adapted to combination for the purpose named. To carry out the object requires that the movements be transmitted to a convenient distance where they may be recorded on the surface provided. To do this with fidelity and convenience has been the problem to be solved. Accordingly, Marey devised and has employed the tambour system, and utilized the contained air as the medium of transmission. I devised and employ a modified tambour arrangement, and utilize water as the medium of transmission.

The pertinent question has arisen as to which of the two is the better medium. Marey, in his former experiments on animals, failed with water, but achieved brilliant results with air. I, in my experiments on man, have succeeded with water, and found this medium so efficient and convenient that I thought it left nothing to be desired. Marey believes that the inertia of the liquid column tends to deform the movements, while air, by its lightness, obviates this source of deformation. I believe that, in a proper apparatus, the inertia of the liquid column is reduced to an inappreciable minimum, and this medium, by its incompressibility and easy displacement, transmits the movements with unerring fidelity; while air I have mistrusted on account of its easy compressibility. The question, however, can only be settled by the results of experiment.

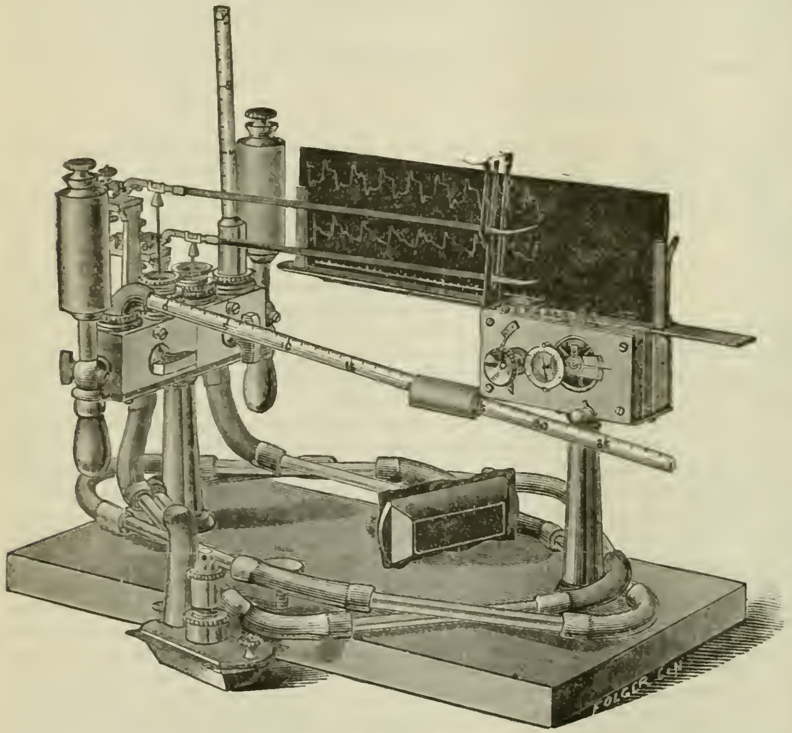
My compound sphygmograph is constructed for water, yet it yields fair results when used with air. Whether these results will compare favorably with those of which Marey's improved polygraph is capable I have not at present the means of knowing; only among traces I have seen that were taken by the *sphygmographe à transmission*, which embodies the same principle, there are none superior to those my instrument is capable of, charged with air instead of water. To aid in the solution of the question I recently instituted the following comparative experiments

My two radial pulses are synchronous, as proven by many observations.

Experiment 1.—With the two instruments of my apparatus prepared and adjusted as usual, I removed the liquid from the one that writes below, and left the other filled. Two assistants then applied them to my radials—the one filled with water to my left, the other filled with air to my right. They were manipulated until the levers displayed their best movements, and then the traces were taken. No. 1 shows the trace of the left radial by water; No. 2 of the right radial by air. This experiment was several times repeated with very similar results. We notice at present the marked contrast in the amplitude and definition of the two traces.



Experiment 2.—The same basal chamber was completely filled with water, leaving the transmission tube and upper chamber containing air. The instrument was then applied to my right radial and the best trace obtained; 3 is the result. This will be noticed as a very beautiful trace, of small yet larger amplitude than 2, and with secondary waves distinctly marked.



COMPOUND SPHYGMOGRAPH.

Experiment 3.—The same instrument completely filled with water and my right radial traced; 4 gives the result—a perfect trace, amplitude nearly twice that of 3 and about three times that of 2.

Experiment 4.—A child two and a half years old was the subject. With instrument adjusted as in the other experiments, 5 was obtained with water and 6 with air, as the best traces the same pulse would yield under the respective media.

These results all go to show that under the same or parallel conditions water produces a trace of much greater amplitude and better definition than air; although aside from difference of amplitude the two traces in general form are quite similar. The contrast proves that in transmission by water the force of the pulse is conserved, while by air it suffers loss; and herein lies the great superiority of water over air as a medium—water thus becoming applicable for tracing the weakest movements, while air in these conditions produces no tangible results. Both Marey and François Franck testify to the difficulty of obtaining traces of feeble movements by the *sphygmographe à transmission.*[*]

In regard to form, these traces[†] by water are as nearly faultless as any that could be produced by the best direct sphygmograph. It would be difficult to notice in them any effect of inertia of the liquid column. And No. 2 by air, so far as its meagreness will permit, shows a correct outline.

Attention is now called to traces 1 and 2, taken simultaneously. It will be observed that the position of the signal lines A, A, with respect to the beginning of the ascents, appears to be the same in both lines. If this be so, the beginnings of the traces are synchronous, and, the pulses being synchronous, their beginnings must have been transmitted by the different media in equal times.

However, it should be remarked that a slight discrepancy may exist and be unnoticed, because of the uncertainty as to the exact position of the basal points in the long turns of the air traces. The result shows at least great promptness in the transmission by air, and whether this be really more rapid than by water will be seen farther on. The relationship shown is different from what I had *a priori* expected. I inferred that the air under the stroke of the pulse would be compressed for a time, before the lever would rise, and thus the start would show delay as compared with that by water. But the fact would seem to be, that the air in order to actuate the instrument first becomes condensed under the requisite pressure, and then behaves as a practically incompressible medium within the forces engaged.

---

[*] . . . ; malheureusement, le sphygmographe à transmission est moins sensible que l'instrument direct et ne donne de bons tracés que sur les sujets dont le pouls est assez fort."—La méthode graphique, p. 585.

[†] Unhappily the engraver has failed in some instances, notably in the direction of the up-strokes, to follow exactly the lines of the originals.

11

In order to test more rigidly the fidelity of the time results obtained with the two media as employed in my apparatus, I made the following further experiments:

Experiment 5.—Object: to test the correctness of water to show the time relation of two phenomena. *Details:* Apparatus, except the carriage, prepared and adjusted as I usually employ it in clinical observation. Tubes, twenty-six inches long between membranes, about one-sixth of an inch bore, composed of alternate sections of glass and firm rubber tubing. Membranes respectively at standard tension; levers six inches long, with pin-socket half an inch from axis. The two bases were firmly secured in a block, side by side with membranes looking upward. Two similar corks transfixed by a metal rod were placed one upon each membrane, and a metal bar of sufficient weight was placed, with one end on the rod, the other on a support. A touch of the bar would instantaneously affect the basal membranes, and the motion in due time would be communicated to the levers, and written by them on the advancing slide. If the apparatus were true, the records of a motion thus communicated to the membranes would be synchronous. To show more plainly any succession, a carriage was substituted whose speed was much greater than that ordinarily used. The usual chronograph, writing seconds and fifths was employed. When all was ready, while the chronograph and slide were in motion, I made a series of quick taps with my finger on the bar, and thus obtained two lines of traces. Immediately the slide was repassed, and halted at the points where the levers and basal points of the traces were in, or nearly in, conjunction, and then the levers were made to describe their curves by pressing on the membranes. The relations of these curves, termed signal lines, to the basal points, respectively indicates the synchronism or succession of the records. The result of the experiment is shown in No. 7. The basal points and signal lines, above and below, are precisely in the same relation, which proves that the two instruments transmitted and recorded the same movement in exactly equal times.

Experiment 6.—Object: to test the correctness of air to show the time relation of two phenomena. *Details:* The same as in last experiment, except that the instruments were charged with air instead of water. Result shown in No. 8. Here, too, the traces are uniformly synchronous.

Experiment 7.—Object: to test the difference in time of transmission by water and air. *Details:* The same as in Experiment 5, except that the upper instrument was charged with water and the lower with air. Result shown in No. 9. The eye can readily detect a difference in favor of an earlier elevation of the traces by air. The difference is small, and measures, I believe, about $\frac{1}{130}$ of a second. The proof is positive that in my instrument a movement is more rapidly transmitted by air than by water.

Experiment 8.—Object: to determine the time consumed in the transmission of a movement by water through my instrument as usually employed. *Details:* A crank moving vertically on a central axle was so placed in relation to the instrument that one arm bore upon the basal membrane of the upper instrument, and the other arm supported directly the lever of the lower instrument. The same bar was placed with its end resting on the arm that pressed the membrane. Tapping the bar would raise the lower lever instantaneously, and the upper after the movement had been transmitted through the channel of the instrument. Thus the experiment was made, and the result is shown in No. 10. The delay seems to measure about $\frac{1}{65}$ of a second.

Experiment 9.—Object: to determine the effect of tubes of different lengths on transmission by water through my instrument. Details: The same as in Experiment 5, except that the lower instrument was furnished with a tube fifty-eight inches long, while the tube of the upper remained twenty-six inches. Result shown in No. 11. Delay of the long tube over the other is measured at about $\frac{1}{55}$ of a second.

These experiments were all several times repeated, with great uniformity of the time results.

CONCLUSIONS.

1. Both water and air are reliable as media of transmission for movements within their respective ranges of availability.

2. Water transmits movements with much greater power than air, which gives it a wider range of application, embracing feeble movements that air is incapable of inscribing.

3. With a proper apparatus, properly adjusted, the form of a movement as transmitted by water is entirely correct; the form, also, as transmitted by air, may be correct.

4. The time relation of two movements may be uniformly correctly shown by either water or air—provided respecting the latter the movements be sufficiently strong.

5. The time lost in the transmission of a movement is greater by water than by air, and by either is in proportion to the length of the tube.

6. In order to show with precision the synchronism or succession of two movements, both instruments must be charged wholly with water or wholly with air, and both transmission tubes must be of the same length.

In practical effect the foregoing experiments demonstrate the fidelity and availability of my method to show the form and synchronism or succession of movements, great and small. They go, also, to show the fidelity of Marey's method for the purposes named, within the range of its availability. Hence, the results which have been achieved by the careful application of either method, may be accepted as rigidly true. If improvement in Marey's apparatus shall be found to adequately enhance its force of transmission, then the choice between his method by air and mine by water will be governed by less weighty considerations than difference in energy of transmission.

REPORT OF CASES OF PHTHISIS

Treated at Aiken, S. C., During the Season 1879–80.

By W. H. GEDDINGS, M.D.,

AIKEN, S. C.

(Continued from Medical Record, November 15, 1879, p. 469.)

My report of cases of phthisis treated at Aiken in the season of 1878 and 1879, and published in the Medical Record of November 15, 1879, closed with the following summary: Arrested, 4; improved, 13; unchanged, 5; grew worse, 8; died, 1; total, 31. Of these eight returned to Aiken or reported at Bethlehem, N. H., and thus afforded me an opportunity of continuing their case histories.

Case XVII.—(Dr. R. P. Lincoln). This patient passed the greater portion of the summer at Bethlehem (White Mts.), improving at first and then losing ground in consequence of an ill-advised trip to New York, during which she was exposed to great fatigue and suffered much from the heat. After this she again improved, and remained tolerably well until October, when she started for Aiken.

November 6th.—Pulse, 80; temperature, 99⅓°. Looks very well and has a healthy color. There is evident depression of the upper portion of the thorax on the left side. The percussion sound is much more resonant over the upper portion of the chest, but the area of dulness to the outer side of the heart is now quite distinctly defined, extending two inches upward into the axilla. Everywhere else there is normal resonance. Patient completed her fourth season in Aiken without relapse or any untoward accident, and is now doing well.

Case V.—(Dr. Morrill Wyman). I had the pleasure of meeting this patient at Bethlehem. He had steadily improved, and for some months past had been entirely free from cough. Being rather nervous, he refused to submit to an examination, but his general appearance is that of a person in perfect health. His ruddy color, his increased weight, the cessation of his cough, and the absence of all subjective symptoms warrant me in classing him among the cases in which arrest has taken place.

Case XXIX.—(Dr. Calvin Ellis). It will be remembered that this patient, after great improvement, was much prostrated by a severe attack of diarrhœa, during which he lost even more than he had gained, and for that reason he was classed among the cases that *grew worse.* Fortunately, the diarrhœa exercised no unfavorable effect on the progress of the disease, and during his residence at his home in Vermont he gradually regained all he had lost during the attack, improving slowly during the summer and more rapidly during the fall months. Arrived in Aiken November 6th, and has been improving ever since.

November 12th.—Pulse, 80; temperature, 99°; weight, 137½ lbs. Coughs three or four times in twenty-four hours, raising each time a small quantity of muco-purulent matter. Dull on the right side from above clavicle to the upper border of third rib, and between the scapula and vertebral column, the respiration being bronchial in character.

December 10th.—Has continued to improve. Pulse and temperature are normal, and his weight has increased to 140½ lbs., a gain of three pounds since October 12th. Cough has ceased almost entirely, a little hack after breakfast being all that is left of it.

January 10, 1880.—Improvement has continued without interruption; has not missed a meal since his arrival in Aiken; has attained his full average weight, and presents the appearance of a person in perfect health.

Right side.—The dulness in front extends now only to the lower border of the first rib; posteriorly it remains unchanged. Respiration slightly bronchial.

April 24th.—Notwithstanding several weeks' confinement to the house with an old gunshot wound, the patient has continued to improve. The little hack in the morning noted at the last examination has disappeared, and for six weeks there has been no cough of any description. Pulse and temperature remain normal. There has been no further change in the physical symptoms except diminution of the area of dulness behind, which is now confined to the space above the spine of the scapula, and between that portion of the bone and the column.

Remarks.—The above is the most remarkable case of arrest of phthisis that has ever come under my observation. At one time, in the spring of 1879, he was so pale and emaciated, and the temperature so persistently high, that a fatal termination appeared to be inevitable. I heard from him in July, 1880, and up to that time no relapse had taken place. There being no business opportunities in Aiken, and not deeming it prudent to return to his old home, he went to Colorado. The climate there not coming up to his expectations, he has concluded to return to Aiken.

Case XIX.—(Dr. Chapman, of New Haven). Improved a little after his return home. He then went to Colorado, and passed the summer there with some advantage to his general health. On the approach of cold weather, not feeling as well as usual, he returned to Aiken, remaining there several months. An examination made in January showed that there had been no change in the extent of the infiltration, and that his general health was precisely the same as at the time of his arrival in Aiken one year ago. When seen again he had improved, and had added three pounds to his weight.*

Case II.—(Dr. Busey). Passed his sixth season at Aiken enjoying his usual health, and in the same condition as the close of the last season.

Case XIV.—(Dr. Burton, of Adams, Mass.). The wonderful improvement which took place in this apparently hopeless case caused me to look forward with much interest to her return. On leaving Aiken last spring she was advised to return early in October. Unfortunately, this advice was not followed. She continued to do well throughout the summer, but about the second week in October an abscess formed in the diseased lung which, making its way into a bronchus, discharged very profusely. This reduced her considerably and caused her to lose all that she had gained in weight during the previous winter. She was sent over to some place in Connecticut where she improved a little, but was unable to undertake the journey south until January.

January 13th.—Pulse, 86; temperature, 99½°. Weight, ninety-two and a half pounds, which is within two and a half pounds of her weight when she arrived in Aiken one year ago. Expectorates one-half to one ounce. Tongue coated and yellow; appetite poor; has not been able to take oil for some time past.

Right side.—Diminished resonance under clavicle down to second rib, with complete dulness everywhere else. The dulness does not disappear with change of position. Respiration bronchial, with prolonged experium, moist râles everywhere audible.

February 13th.—Notwithstanding the unpromising condition of the patient when she first arrived, there has been a steady improvement, and she has gained five and a half pounds. Takes long walks without being fatigued.

February 28th.—Catamenia, which had disappeared during the fall, have returned. Coughs but very little, and has scarcely any expectoration.

March 16th.—Since the last date her appetite and digestion have failed, and she has gradually lost six pounds.

April 19th.—Patient has to some extent recovered the ground lost during the last month; her strength is improved, and her color is remarkably good. Continues to cough but little, and does not expectorate more than a teaspoonful in a week. Has regained two or three pounds of the flesh lost during the late attack. Goes north.

Result.—Marked improvement, rapid increase in weight and strength, with lessening of cough and expectoration.

Remarks.—The renewed improvement in this case (one with total filling of the lung with cheesy infiltration), especially after the relapse in the fall, makes this case one of the most interesting of the whole series.

Case X.—(Dr. George C. Webber, of Millbury, Mass.). This patient, who at the time of her arrival had an infiltration of the apices of both lungs, improved steadily, the area of dulness disappearing entirely on one side, and being greatly reduced on the other. With the exception of one or two "colds" she did well throughout the summer.

---

* This patient died suddenly after his return home. No autopsy was made, but it was supposed that his death was the result of cerebral hemorrhage.

February 24th.—Pulse, 104 (under nervous excitement); temperature, 98½°. Her general appearance is that of a person in perfect health. She lost a little in weight during the summer, but has gained one and a half pounds since her return to Aiken, and now weighs 112 lbs. The only physical signs of disease are diminished resonance under the left clavicle, with bronchial respiration behind.

April 19th.—Has improved steadily, her flesh is firm, her color ruddy, and her weight has increased from 110½ to 116 lbs. She walks long distances without experiencing the slightest fatigue. She coughs only in the morning, and then very little. With the exception of slightly diminished resonance above the clavicle, physical examination reveals no evidence of the old infiltration.

Remarks.—Were it not for the occasional cough in the morning this would also be regarded as a case of arrest.

Case XXIII.—(Dr. Van Bibber, Baltimore). This patient, whose improvement was so marked during the past season, had no relapse during the summer and fall, but lost eight or nine pounds.

April 6th.—His appearance is that of a perfectly healthy man. He coughs occasionally throughout the day and expectorates about a half an ounce, mostly mucus.

Patient has been two months in Aiken and during that time has gained ten pounds. Pulse and temperature are normal. The only physical symptom of the old disease is diminished resonance under the left clavicle. This patient may be regarded as nearly well.

It will be seen in this supplementary report that the disease was arrested in six out of the thirty-one cases, and that in two more, X. and XXIII., there is every prospect of speedy recovery.

Thus corrected, the summary for the season 1878–'79 would read: Arrested, 6; improved, 13; unchanged, 4; grew worse, 7; died, 1: Total, 31.

The report for the past season, 1879 and 1880, includes thirty-eight cases, of which I have been able to preserve a tolerably complete record. Including as it does only those that were under observation for at least six weeks, it contains the worst cases; the lighter ones—and such are always in the majority at a health resort—were naturally less regular in their attendance, and are consequently excluded from this report. The cases are not selected, but taken as they appear in my daily record of practice. It contains no case in which there were not positive signs of chronic infiltration of the lungs. Not deeming it expedient to publish the names of private patients, I have, in nearly every instance, identified the case by giving the name of the medical attendant or that of the consultant.

Case XXXII.—A young man, twenty-four years old, from Burlington, N. J., a patient of Dr. Grant. Does not know whether there is any hereditary predisposition to consumption in his family. He began to cough in July, 1879, and shortly afterward had a slight hemorrhage, which, in its turn, was succeeded by night-sweats and loss of flesh. He has lost in all twenty pounds, his present weight being 120 lbs.

October 20th.—Color pale; pulse, 112; temperature, 100.2°. Expectoration muco-purulent in character and small in quantity.

Left side.—There is dulness in front, from the clavicle to the heart, and behind, from the upper border of the scapula to its lower angle. The respiration over the front is bronchial in character, with prolonged experium; posteriorly the respiratory murmur is indistinct.

Right side normal, except that the respiration over the apex is harsh, with prolonged experium.

November 3d.—Pulse, 108; temperature, 100.2°. Looks much better, is stronger, has gained five pounds in two weeks, and the sweats have ceased entirely.

November 20th.—Pulse, 100; temperature, 99.5°. Weighs 130 lbs., a gain of ten pounds during the month.

December 8th.—Pulse, 98; temperature, 99°. Has continued to improve, looks well, and coughs but little. Weighs 132½ lbs., a gain of twelve and a half pounds.

January 10th.—Pulse, 96; temperature, 90°. Looks fresh and ruddy, and has the appearance of a person in good health. His present weight is 136 lbs., a gain of sixteen pounds since his arrival in Aiken. Coughs only once in three days, on which occasions he expectorates only a little pellet of mucus.

March 8th.—Color rosy; never coughs except after some unusual exertion, such as a fit of laughter. The area of dulness in front has become more resonant, especially below the clavicle and near the sternum. The dulness now does not extend lower than the third rib. Behind, the dulness reaches from the spine of the scapula to its lower third, the region above the spine and the lower third having become resonant. The respiration is no longer distinctly bronchial, but rather undecided in its character.

Results.—A gain of sixteen pounds, disappearance of all febrile symptoms, entire cessation of sweats, almost complete cessation of cough and expectoration, and great improvement in general health.

Case XXXIII.—Male, about twenty-two years of age, patient of Dr. Shurly, of Detroit. Family history not noted. Had severe cough in August, 1878, which was followed by fever, intermitting in type and attended with profuse sweats. Has lost twenty-eight pounds.

October 22d.—He looks very ill, is pale and cachectic in appearance, quite feeble and greatly emaciated, his present weight being only 112 lbs. Pulse, 108; temperature, 100.2° (at 11 A.M.). Left front dull from clavicle to fourth rib, with tympanitic resonance and *bruit de pot fêlé* under second and third ribs. No dulness elsewhere. Auscultation on left side reveals bronchial breathing, with prolonged experium and loud amphoric respiration, corresponding with the area of tympanitic resonance. On the right side the respiration is bronchial, with prolonged respiratory murmur.

October 31st.—Temperature has risen steadily from 100.2°, on 22d, to 102.7° to-day. Is much weaker.

November 10th.—Continues to grow weaker every day. Temperature, 103°.

November 24th.—Has had less fever since the 16th, but there has been no improvement in any other respect. Feeling much discouraged, he insists upon going to Florida.*

Results.—Rapid decline, with steady rise of temperature and increased emaciation.

Remarks.—This was evidently a case of subacute tuberculosis, with extensive breaking down of lung-tissue. His condition at his time of arrival in Aiken was such as to preclude all possibility of even temporary improvement.

---

* A letter from his physician in Jacksonville announced his death at that place two weeks after his arrival there.

Case XXXIV.—A married lady from Brooklyn, thirty-six years of age, patient of Dr. Barker, of Morristown, N. J. Disease began with cough in January, 1879; had a series of moderate hemorrhages, night-sweats, etc.

October 27th.—Looks very pale and is much emaciated, her present weight being only ninety pounds. Expectorates two ounces of muco-purulent matter. Pulse, 84; temperature, 100° at 11 A.M., but is said to be much higher in the evening.

Right side.—Dulness from clavicle to second rib in front, and half down the scapula behind. The respiration both front and back is bronchial, with numerous moist râles. Conducted heart-sounds distinctly audible. The general appearance of the patient is extremely unfavorable. In addition to the pulmonary disease there is a uterine complication which, by interfering with locomotion, prevents her from taking exercise in the open air.

The day after the above examination the patient was seized with an obstinate attack of diarrhœa, ten days elapsing before it yielded to treatment. During the month of December there was considerable fever, the temperature at times rising to 103°. Emaciation progressed slowly but steadily during this and the following month, the patient being very ill most of the time. During January the weakness had increased to such an extent as to confine her to bed, and notwithstanding the greatest care a troublesome bed-sore developed over the sacrum. The emaciation continued to progress through the month of February, the patient becoming so reduced that she presented the appearance of a living skeleton. Another sore developed on her left shoulder, and to add to her sufferings the mucous membrane of her mouth became covered with painful aphthous ulcers. She was relieved by death on the 25th of February, having steadily declined from the time she first came under observation.

Remarks.—This case was so manifestly hopeless from the very first that no notes were taken of the condition of the lungs after the first examination.

Case XXXV.—From Cohasset, Mass.; male, fifty-six years (Dr. Spalding). Commenced to cough in the spring of 1879, lost five to eight pounds, and has had night-sweats.

November 28th.—Pulse, 88; temperature, 99.2°. Color pale. Expectorates one ounce, all of which floats. Present weight, with overcoat, 140 lbs.

Right side.—Dull from clavicle to third rib in front, and to one and a half inches below the spine of the scapula behind. Auscultation: bronchial respiration over the upper portion of the lung, both front and back.

February 19th.—There has been a slow but steady improvement. He coughs much less, and the expectoration is reduced to one-third of what it was at the time of his arrival. There has been little or no fever, the pulse ranging from 72 to 84. His color is better, and there has been some increase in weight. Physical examination shows marked improvement, the lower border of the area of dulness in front having receded to the second rib, while behind it cannot be detected below the spine of the scapula.

Result.—General improvement, with lessening of the area of dulness and slight increase in weight.

Case XXXVI.—A gentleman from Canada (Dr. Boswell, of Quebec, and Dr. Campbell, of Montreal), fifty-six years. Took cold in September, 1879. Suffered much with attacks of congestion of the lungs, and had several profuse hemorrhages, followed by loss of flesh and night-sweats.

November 25th.—Pulse, 84; temperature, $99\frac{1}{2}$°. Patient is very thin; collar-bones very prominent, with sinking-in of the supra-clavicular regions. Breathes very rapidly, and coughs incessantly, expectorating a large quantity of muco-purulent matter, a considerable proportion of which sinks to the bottom of the vessel. Sweats profusely. Severe pleuritic pain in the left side. Appetite poor and digestion much impaired.

Left side.—Dulness extends from the clavicle to the heart, with diminished resonance lower down. Posteriorly there is marked dulness under the supraspinous fossa.

December 8th.—Pulse, 84; temperature. $100\frac{1}{3}$°. Flushing of face, respiration very rapid, complains of pain at the lower border of the infiltration. Dulness has extended downward, and now occupies the upper half of the chest.

December 28th.—Patient has grown thinner, the dyspnœa has increased; is weaker, and suffers with frequent attacks of indigestion. Night-sweats continue to recur.

January 10th.—An abscess has formed on the outer side of the anus, causing great suffering. An opening afforded prompt relief.

It is useless to follow the details of this case. The already enfeebled digestion grew weaker, and it was only with the greatest difficulty that he could be induced to take even small quantities of food. The emaciation, of course, progressed steadily, and with it the weakness of the patient continued to increase. As soon as the weather became sufficiently warm to admit of his removal, he was taken by slow stages to his home, where he died a short time after his arrival.

Result.—Extension of the disease.

Remarks.—In this case a fatal termination was inevitable. The extent of the disease, the dyspnœa, but more especially the condition of the digestive organs, leaving no room to hope for a more favorable result.

Case XXXVII.—A young lady, twenty-four years, patient of Dr. Pepper, of Philadelphia. The disease dates from an attack of acute pneumonia in January, 1879. Cough has persisted ever since, with a loss of ten pounds in weight.

November 28th.—Pulse, 124; temperature, $101\frac{3}{5}$°. Color pale. Has dyspepsia, associated with great nervousness, and is subject to severe fits of nervous depression. Has but little appetite, and is full of unreasonable fancies in regard to the character of her food. Has an almost invincible repugnance to anything in the shape of medicine. She is very weak, and cannot walk from her room to the adjoining veranda without assistance.

Right side.—The thorax on that side does not expand during inspiration. There is dulness over the whole front, from above the clavicle to the liver, in the axillary line from the arm-pit half-way down toward the liver, and behind from above to two inches below the spine of the scapula. Auscultation: bronchial breathing, with distinctly prolonged experium over the upper portion of the chest, in front, with crepitation below. Behind, the breathing is bronchial, with prolonged expiratory murmur, and in one place cavernous respiration. Exquisite bronchophony. Nothing abnormal on the other side.

December 21st.—Has gradually grown worse. Cough very persistent, and at times almost incessant. Is troubled with pharyngitis, which is very painful, and interferes with deglutition. Is evidently much weaker, and is losing flesh daily. Cavernous respiration is now also audible in front.

December 26th.—Pulse, 126. Wanders in her talk, and is rapidly failing.

December 31st.—Pulse, 125. Appears to have rallied a little, but is still delirious.

January 15th.—But little change took place in the condition of the patient until a few days ago, when she refused to take nourishment. Since then she has grown every day weaker, the delirium continuing all the while. Death at 4 P.M.

Result.—Steady destruction of lung tissue, with death seven months after the first attack.

Remarks.—The great extent of the disease, involving nearly the whole of one lung, its rapid and uninterrupted course, the inability of the patient to take food and remedies, and her peculiar nervous disposition, caused me to express an unfavorable prognosis when I first took charge of the case. It was acknowledged that she was brought to Aiken as a *dernier ressort*.

CASE XXXVIII.—A young man of twenty-four years, patient of Dr. Thomas Reiley, of Adams, Mass. Disease began in May, 1878, with cough and pleuritic pain. This was followed by fever, night-sweats, and loss of flesh. Family history not noted.

November 29th.—Pulse, 92; temperature, 100.5°. Pale, cachectic appearance. Weight, 128 pounds. Suffers with profuse sweats.

Right side.—There is dulness in the supra-clavicular region and under the clavicle, also in the axillary region and under the supra-spinous fossa. There is, besides this, a patch of dulness to the outer side of the scapula. Auscultation reveals bronchial breathing over the apex in front, under scapula, and to the outer side of that bone.

December 28th.—Pulse, 86; temperature, 99½°. Great improvement in color. Cough and expectoration much lessened. Sweats have ceased, and his weight is 135 pounds, a gain of seven and a half pounds.

March 7th.—Has had an occasional rise in temperature, but has done well in other respects. Pulse, 92; temperature, 100.4°. The dulness has disappeared, except under the clavicle and supra-spinous fossa. Respiration feeble and indistinct. Weighs 138½ lbs., a gain of ten and a half pounds.

March 16th.—Pulse, 84; temperature, 99°. Has had a severe attack of gastric catarrh, and has also suffered with headache, formication over the whole of the left side, burning of the palms of the hands and of the soles of the feet, together with other obscure nervous symptoms. He has recovered from these attacks, but has lost five pounds.

April 12th.—Pulse, 80; temperature, 99.3°. Has entirely recovered from his late sickness, looks quite well, and is able to walk ten miles without experiencing fatigue. Has regained several pounds of what he lost in weight during the late attack, and now weighs about 136 lbs. The dulness has disappeared everywhere, except over the supra-spinous fossa, and between that portion of the scapula and the column. The bronchial breathing has given place to normal respiration.

Result.—Diminished cough and expectoration, cessation of sweats, a gain of eight pounds in weight, disappearance of all physical signs of disease, except at the apex, and great improvement in general health.

CASE XXXIX.—A young lady from Elizabeth, N. J., patient of a homœopathic practitioner of that place, twenty years of age. Her present sickness dates from an attack of bronchial catarrh in the spring of 1877. Has had several hemorrhages, and has lost fifteen pounds. Has had attacks of fever, intermittent in type, supposed to be malarial, but which were, in all probability, hectic. Suppression of catamenia for several months.

December 1st.—Pulse, 112; temperature, 105.5°. Pale, with bright red spots on the cheeks, respiration hurried, her general appearance being that of a very sick person. Expectoration copious. Present weight, 114½ lbs. Examination made some time later showed an extensive infiltration occupying nearly the whole of the upper half of the left lung.

January 21st.—Pulse, 96; temperature, 100.3°. The fever continued to recur until about two weeks ago, since which time there has been slight improvement in her symptoms, and a gain of two pounds.

February 12th.—The improvement noted at the last visit proved to be of short duration, and she is now evidently much worse. The patient, thinking that a change would prove beneficial, removed to Georgia, and was lost sight of.

Result.—Slight improvement, with a gain of two pounds; subsequent relapse and rapid decline.

Remarks.—This case was from the first a hopeless one.

CASE XL.—Male, eighteen years, St. Louis; Dr. P. G. Robinson. Parents both alive; no hereditary predisposition. After confinement and overstudy at school, patient began to cough, had several hemorrhages, and lost ten pounds in weight.

December 6th.—Pulse, 96; temperature, 100.2°. Present weight, 165 lbs. Expectorates about two ounces, all of which floats. Can lie on either side with comfort. Has night-sweats.

Left side.—Dull in front from clavicle to third rib, that portion of the chest-wall being depressed and expanding but little during inspiration. Behind there is a small area of dulness under the supra-spinous fossa. Prolonged expiratory murmur and conducted heart-sounds. On the right side no dulness, but harsh inspiratory murmur with prolonged experium.

December 31st.—Pulse, 92; temperature, 99°. With the exception of a slight attack of fever on the 19th there has been steady and uninterrupted improvement. He looks much better, coughs less, and expectorates only three-quarters of an ounce instead of two ounces. Sweats have ceased entirely, and he has regained two pounds.

January 18th.—Continued improvement; weighs 168 lbs., a gain of three pounds.

February 6th.—Pulse, 104; temperature, 100. Took cold on 28th, and has had fever and pleuritic pain ever since. Has lost four pounds since January 18th.

March 16th.—Fever has persisted, and patient has continued to grow worse ever since the exacerbation in February. Left Aiken for North Carolina.

Result.—Marked improvement followed by relapse.

CASE XLI.—A young girl of sixteen years, a patient of Drs. Powell and Donaldson, of Baltimore. Has had cough and fever since last June. Has lost twenty-five pounds. Family history not noted.

December 16th.—Patient looks pale, but, notwithstanding her great loss of weight, does not present the appearance of an emaciated person. Pulse, 104; temperature, 101½°.

Right side.—Dull from clavicle to second rib in front, with diminished resonance over the upper portion of the lung behind. Respiration undecided over front and back, with prolonged expiratory murmur.

February 6th.—Improvement has been retarded by a variety of intercurrent troubles, such as dyspepsia, sick headache, and diarrhœa, but in spite of all these drawbacks she has made some progress. Pulse, 104; temperature, 99.5°. Her color is more healthy. The area of dulness is diminished, and is now confined to the clavicular region.

March 1st.—Much improved, her weight having increased from 105 to 109½ lbs.

May 2d.—Pulse, 96; temperature, 100½°. The dulness in front remains confined to the clavicular region, but behind it cannot be detected below the spine of the scapula.

Result.—Improvement in general health, diminution in the extent of the area of dulness, and a gain of four and a half pounds.

Remarks.—There was in this case no very striking improvement, but when the age of the patient is taken into consideration, together with the constantly recurring attacks of gastric catarrh, the result is far better than could reasonably have been expected.

Case XLII.—A married lady, thirty-three years; patient of Dr. S. Forman, of Jersey City; hereditary tendency to pulmonary disease, an aunt on the mother's side having died of consumption. In the fall of 1877, after having been much prostrated by the fatigue and anxiety occasioned by the illness of one of her children, she began to cough, but did not lose much flesh until a year later, when she was attacked with chronic diarrhœa which reduced her considerably.

December 31st.—Pulse, 96; temperature, 99°. Patient is very pale, does not know her weight, but is evidently much emaciated. Tongue coated, appetite poor, suffers with dyspepsia, and has frequent attacks of diarrhœa. Has uterine disease, with profuse leucorrhœa. Physical examination of the chest reveals extensive disease of the upper portion of the right lung. On the left side no dulness, but occasional moist râles.

February 9th.—Patient's condition remained unchanged until about the 4th of February, from which time there has been a marked improvement evidenced by increased strength, some gain in weight, and less cough.

February 23d.—Has been hoarse for several days, and has had attacks of fever. Laryngoscopic examination reveals ulceration of the right vocal cord. Is much worse.

March 21st.—Patient having grown weaker and more emaciated was advised to return home.

Result.—Slight improvement at first, subsequent relapse, and extension of disease to the larynx.

Case XLIII.—H. B——, colored female, about fifty years of age. This patient consulted me in 1870 on account of persistent cough and loss of flesh, accompanied with slight fever. Physical examination revealed consolidation of the upper third of the right lung. She gradually regained flesh and strength, the cough disappeared, and with it the other symptoms of pulmonary disease. She has remained well ever since, and has been able to resume her usual work.

December 31st.—Ten years have elapsed since her first examination; there has been no return of cough or of any other symptoms of lung disease; the pulse is somewhat accelerated (92), but there is no corresponding rise of temperature. The only trace of the disease present is an area of dulness on the right side, extending from above the clavicle to the upper border of the second rib. She has had no threat of a return of the old disease, and although well advanced in years is able to do a full day's work as a washerwoman.

Result.—The absence of any symptoms of disease during the past eight or nine years justify the conclusion that the phthisical process has been completely and permanently cured.

Case XLIV.—Male, twenty-five years; from Malden, Mass.; patient of Dr. Bemiss, of Medford, Mass. Heredity on the maternal side, and two brothers have died of phthisis. The disease began with a slight attack of hæmoptysis in May, 1878. This was followed with loss of flesh and night-sweats. Had another hemorrhage in April, 1879, much more profuse than the first, and then began to cough. Went to Minnesota, where he for a time ceased to cough. Over-exerted himself, brought on profuse hemorrhages and a return of his cough. The hemorrhages continuing to recur, he started for Aiken.

January 1, 1880.—Pulse, 100; temperature, 100°; weighs 126 lbs.; color good.

Right side.—Dull from the clavicle to the second rib, with diminished resonance under the third. Respiration bronchial, with jerking expiration. Behind, the dulness extends over the upper two-thirds of the scapula. There is no dulness on the left side, but the respiration is very harsh. Moist râles over both lungs. Expectorates one-half ounce, some of which sinks. Can now lie on both sides, which he was unable to do during the summer. Prognosis favorable. Patient improved steadily, the temperature sank to 99.5°, and he gained two pounds in weight; the cough became much less troublesome, and the expectoration ceased altogether. During the month of March an abscess formed near the anus, and developed into an exceedingly troublesome and very painful fistula. This prevented any further increase in weight, but seemed to benefit the local symptoms in the lung, the cough ceasing entirely after the opening of the abscess. At the time of his departure he was suffering too much to submit to an examination, but I afterward met him at Bethlehem, and found him quite well. There had been no return of the cough, and his general appearance was that of a healthy man. Physical examination showed a reduction in the size of the infiltration, the dulness extending in front from below the clavicle to the second rib, while, behind, the only evidence of disease is diminished resonance between the upper portion of the scapula and the vertebral column. The fistula had been operated upon, and was gradually healing.

Result.—Arrest of the phthisical process, increase in weight, and diminution of the area of dulness.

Remarks.—In order that the good result in this case may not be credited to the fistula, attention is called to the fact that a favorable prognosis was expressed at the first examination, and long before its formation.

Case XLV.—A clergyman from Morristown, Ohio; age not stated, probably about thirty-five years; Dr. Trimming. There is hereditary predisposition on both sides, several maternal aunts and one uncle on the father's side having died of consumption, as did also the paternal grandfather. Six years ago he began to experience uneasy sensations in the left lung. A year later he had a succession of hemorrhages, but recovered from them without cough. In the fall of 1877, after having been much debilitated by the summer heat, he became hoarse, and began to cough. During the following spring (1878) the cough disappeared, and he gained four pounds. This improvement lasted until July, when fever set in, with the return of cough and rapid loss of flesh (twenty pounds). Has improved since his arrival in Aiken, having gained six pounds.

January 23d.—Pulse, 96; temperature, 101°; weight, 126 lbs.

Left side.—Some depression, and imperfect expansion. Dull in front from the clavicle to the cardiac region. In the axillary line the dulness extends half way down. On the back the area of dulness occupies nearly the whole of the upper portion of the chest, extending downward to within one inch of the angle of the scapula, and even below that point the percussion sound is less resonant. Respiration in front feeble and indistinct, except below the outer third of the clavicle, where it is distinctly cavernous. Behind, the breathing is bronchial, and at one point cavernous.

February 23d.—Pulse, 88; temperature, 100.5°. Looks well, coughs less, and has gained three and a half pounds during the month, making a total of nine and a half pounds since his arrival in Aiken. No change in physical signs, except a small spot under the right clavicle, which was probably overlooked at the previous examination.

April 6th.—Pulse, 88; temperature, 103.3°. Patient has lost two and a half pounds, but still weighs more than when he arrived.

Right side.—The disease has extended, as evidenced by dulness extending to the upper border of second rib.

Left side.—Extension of the disease, the area of dulness behind now reaching as low as the angle of the scapula.

Result.—Considerable gain in weight, manifest improvement for about six weeks, and then extension of the disease in both lungs.

Remarks.—The marked improvement in this very unpromising case, during the first six weeks, is worthy of note, and there can be but little doubt that his residence in Aiken not only added to his comfort, but that it also prolonged his life.

Case XLVI.—A gentleman from Croton Landing, New York, forty-two years of age, who has been under the care of a homœopathic physician. Hereditary predisposition on the mother's side. Much exhausted with the cares of business, he was taken in November, 1877, with influenza, at that time endemic in his neighborhood. Scarcely had he recovered from this when he went through an attack of pertussis. These diseases left him with a cough from which he has never recovered. He has had vesperal fever, night-sweats, and loss of flesh.

January 28th.—Pulse, 92; temperature, 99° at 12 M.; weight, 141 lbs.; color bad; expectorates one-half ounce of muco-purulent matter, all of which floats. On the right side there is dulness above and under the clavicle, with diminished resonance as low as the second rib. Over the back diminished resonance to within an inch of the angle of the scapula. Respiration, both back and front, undecided in character.

April 14th.—Pulse, 72; temperature, 99.8°. Patient has improved steadily; has gained four pounds, now weighing 145 lbs., his normal weight; does not cough, and appears to be quite well. Physical examination reveals no evidence of disease other than slightly diminished resonance over the outer half of the clavicle. Respiratory murmur is normal.

Result.—Complete arrest.*

Case XLVII.—A married man about thirty-two years old, a patient of Dr. Riggin Buckler, of Baltimore, who kindly permits me to publish the following extracts from his letters:

"Baltimore, January 25, 1880.

"In 1870 he had trouble at the summit of the right lung; went to China, and returned in 1871 well. The physical signs still show traces of the old disease."

Dr. B. did not see him again professionally until December, 1879, when he sent for him on account of a persistent facial neuralgia, the result of a broken-down condition of health. It was found "that he had been losing weight for some time past, had morning cough, loss of appetite, morning nausea, and shortness of breath. His pulse was quick, 115; temperature, 100°; this at 11 A.M. The dulness over apex of right lung is quite limited, and there are no signs there beyond feebleness of respiration and flattening of the chest-walls. At apex of left lung (upper third) the dulness extends over a greater area. I find increased vocal fremitus, interrupted respiratory movement with feeble and prolonged expiration."

January 29th.—Pulse, 102; temperature, 100.4°; weight, 130 lbs.

February 23d.—Pulse, 102; temperature, 99.2°. Has gained twelve and a half pounds since his arrival in Aiken, and walks six miles by the pedometer without experiencing any fatigue. Coughs and expectorates only in the morning, and has a good color.

March 26th.—Pulse, 96; temperature, 99.3°; weighs 150 lbs., a gain of twenty pounds since his arrival. His general appearance is that of a healthy and robust man. Physical examination reveals a marked diminution of the area of dulness on the left, the lower border of which extends now only to the second rib. With the exception of bronchial breathing at the apex of that side there are no evidences of disease in either lung.

I did not have an opportunity of making another examination, but Dr. Buckler was so kind as to send me the following report of his condition after his return home:

"Baltimore, April 12, 1880.

"W. arrived Saturday night in the midst of a regular March blow, with the thermometer at 32°. I called on him in the morning, and was more than surprised at his wonderful improvement. His gain in the two months, by actual weight, is twenty pounds, and he has the appearance of a well man. His muscles are hard and firm, voice steady, and his skin has the ruddy hue of health. He tells me that he has *no cough whatever;* that he can breathe freely and easily, and that no amount of exercise fatigues or makes him short-breathed. His appetite and digestion are excellent, and he 'sleeps like a top.' His pulse this morning at 11 A.M. was 80, respiration 24, and temperature, 98°. I find he can expand his chest without pain, and freely and easily. I can find nothing wrong on the right side, and, with the exception of a small area of dulness (with feeble respiration) over the upper and anterior surface of the left lung, I can discover no signs of disease either in that lung. Certainly this shows a most marked change as compared with the condition of things when he left this place for Aiken, and speaks volumes in regard to the fitness of the climate there for incipient phthisis.

---

* I had an opportunity of examining this patient in Bethlehem, N. H., in July. Notwithstanding his having gone through an attack of dysentery and malarial fever, the cough had not returned, and the physical signs were the same as at the time of his leaving Aiken.

"Very truly yours,
(Signed) "Riggin Buckler."

Result.—Complete arrest of phthisical process, a gain of twenty pounds, disappearance of all physical signs of disease in the right lung, and marked diminution of the area of dulness on the other side.

(To be continued.)

Progress of Medical Science.

A Peculiar Disease of the Intestine.—Dr. Helweg relates, in the *Hospitals Tidende*, Seite 2, Band VI., the case of an insane peasant, aged forty-five, who had for many years suffered from constipation, pain in the abdomen, and swelling in the ileo-cæcal region. These symptoms came on when he was out of bed, and were relieved when he was lying down. At last he was obliged to remain in bed continually. About every month he had an attack of disorder of the digestive organs—diarrhœa or constipation—which lasted about ten days. In May, 1878, an indolent tumor, feeling like a loop of intestine and yielding a tympanitic sound on percussion, was detected in the right iliac fossa. On deep pressure a sort of crepitation was felt in it; it sometimes suddenly disappeared when friction was made, and reappeared after an interval varying from a few minutes to a day. The patient died in December, 1878, with the symptoms of meningitis at the base of the brain. At the necropsy, miliary tubercles were found in the pia mater, lungs, and liver. The upper part of the cæcum and the lower part of the colon were much distended with gas; then came two contracted portions of colon, separated by a distended portion of the bowel filled with gas; the portion of the colon on the other side of the flexure was normal. In the first of the contracted portions of the colon the mucous membrane formed a sponge-like tissue, the meshes of which and the intestinal space were filled with round scybala; in one place there were two straight channels lying parallel with the lumen of the gut. In the other contracted portion the mucous membrane was thickened, but not spongy. On microscopic examination it was found to have its ordinary structure of intestinal mucous membrane.—*The London Medical Record*, July 15th.

A Simple Apparatus for Artificial Inflation of the Lungs.—Dr. Gadbury, of Yazoo City, Miss., employs a very simple and inexpensive apparatus for artificial inflation of the lungs—a method of treatment which, however valuable, has been greatly restricted in practice on account of the bulk and expensiveness of Waldenburg's apparatus. It consists merely of a Richardson hand-ball and bulb atomizer, in which a mouth-piece has been inserted in place of the spray tubes. The method of its employment is as follows: the patient, having dilated his lungs to the fullest extent, immediately places the tube of the compressor between his lips, closes the nasal passages with one hand, and works the compressor rapidly with the other hand. A few squeezes pump an intermittent current of compressed air into the lungs; as soon as the distention becomes unpleasant, or the need of an expiratory movement is felt, the instrument is withdrawn, to be replaced and re-employed in the same manner a few moments subsequently, the operation being repeated four or five times in succession. In a healthy subject the operation is painless and may be prolonged for a minute or more, but to a person with diseased lungs it is at first disagreeable though not painful. The patient can at first force in but little air, but practice soon enables him to pump it in more freely and for a longer period each day. After frequent use it affords great comfort to those who suffer from a feeling of suffocation and have diminished capacity of the lungs. Dr. Gadbury gives brief histories of a number of cases in which the apparatus was employed with great benefit. He claims that the fresh air thus forced into the lungs expands unused capillary tubes and air-cells, displaces the residual air and noxious gases, excites cough and expectoration, removing morbid secretions at once, and obviating the necessity for expectorant medicines, oxygenates the blood, promotes absorption, relieves dyspnœa, gives impetus to the pulmonary circulation, reduces temperature in fever, and dessicates the fluids in the air-passages. He expects beneficial effects from inflation by this method in croup, diphtheria, bronchitis, asthma, tuberculosis, whooping-cough, asphyxia, chloroform-poisoning, foreign bodies in the air-passages, and many other obstructive lesions of the pulmonary organs. Vapors and gases may also be introduced into these organs by means of this method.

Dr. J. Solis Cohen writes that he has given this plan a trial during the past year. He has found that it cannot be employed safely in all cases in which Waldenburg's apparatus can be employed with advantage, but that it has a sufficiently wide range of utility. In patients liable to hæmoptysis or other hemorrhages, and in certain cardiac and visceral disorders, the intra-thoracic compression, if left to the patient, is apt to be too powerfully exercised, and thus to be absolutely detrimental. He believes that it is seldom safe to use compressed air with a pressure exceeding from one-sixtieth to one-thirtieth of an atmosphere, and quite delicate handling of the ball-compressor is requisite to keep within this limit, while the size of the compressor prevents access of air in large volume, or at constant pressure. He has found the Gadbury particularly useful as a mechanical expectorant.—*St. Louis Courier of Medicine*, August, 1880.

Two Cases of Inversion of the Uterus Mistaken for Polypi.—Dr. Chavernac recently reported the following case to the Société de Chirurgie: A woman, aged fifty-eight years, had suffered since her last confinement, thirty years previously, from a tumor in the vagina, which the physicians consulted unanimously regarded as a uterine polyp. As her health was impaired by it, she demanded an operation, and an ordinary ligature was applied. She immediately complained of pain, which rapidly increased in severity, and a paralysis of the left leg developed. Dr. Chavernac was then called in consultation, and came to the conclusion that the tumor was not a polypus, but an inverted uterus. One of the reasons that led to this diagnosis was the fact that when the tumor was pressed between the finger and thumb it felt as if it were hollow. The ligature was at once removed, but although it had as yet produced very little local effect, the symptoms of peritonitis persisted, and the patient died thirty hours after the operation. In discussing in connection with this case the treatment of inversion of the uterus, Dr. Chavernac insisted that surgical intervention is only justifiable when all the therapeutic measures have failed, and the life of the patient is seriously menaced. If an operation be decided on, the ligature should be chosen in preference to the knife, and preferably the elastic ligature. It must be borne in mind that a ligature badly applied may cause grave accidents.

In the discussion which followed, M. Delens stated that he had once removed an inverted uterus, which was mistaken for a fibrous polypus. A correct diagnosis was rendered very difficult by the fact that the pedicle was very small, scarcely larger in fact than the thumb. The condition of the patient, moreover, was very serious—there was extreme anaæmia, accompanied by a syncopal condition, which would have called for an operation even if a correct diagnosis had been made. The tumor was removed by the ecraseur, the operation lasting twenty-five minutes. The histological examination showed that it was really the body of the uterus with the Fallopian tubes. The patient recovered without any untoward symptoms. A digital examination undertaken some time afterward revealed nothing abnormal—the cervix projected into the vagina in the ordinary manner, and no one ignorant of the facts would suspect that the body of the uterus had been removed. M. Delens has collated the reports of eighty-two cases of excision of the inverted uterus. The ecraseur alone was employed in four of the cases, and in one case the ecraseur and ligature combined. Only one of these five cases terminated fatally, and hence it would be wrong to discard this method of operating. The results of ligature and excision, however, have been still more favorable.

M. Deprés drew attention to the great difference between ablation of the entire uterus, which has very often been followed by death, and amputation of a pediculated portion of the organ. In the latter case the cervix uteri prepares the ground for the operation by the permanent constriction which it exercises. When the inversion is complete, amputation leaves an open wound by which the vagina communicates with the peritoneum.—*Gazette obstétricale*, July 20th.

Fatal Purulent Infection Following an Unopened Abscess of the Thyroid Body.—Dr. Oulmont reports this case, which was observed at the Hôtel-Dieu, in the service of Professor Sée. A robust country girl, aged 26 years, was admitted in June, 1880. Ever since her eighteenth year she had carried a goitre, like most women in her native country. She stated that her menses had on several occasions been accompanied by a slight erysipelas, starting at the nose, occupying only one side of the face, and disappearing in about five or six days. She entered the hospital on account of a similar erysipelas which had appeared simultaneously with her menstruation, but this time, unlike her former attacks, she had suffered from repeated rigors, intense fever, and bilious vomitings during the formation of a little red patch on her left cheek. Moreover, her goitre, until then always indolent, had commenced to enlarge and grow painful.

Examined on admission, her condition was as follows: high fever (105.8° in the axilla), languor, dry tongue, anorexia, some abdominal tension, slight diarrhœa, and an erysipelatous patch on the left side of the nose and cheek. The thyroid tumor had the size of a small orange; showed heat and redness in the median line; pressure there, movements of the neck, and deglutition provoked severe pains. For some time her condition remained unchanged, then the left shoulder became swollen and painful. Repeated rigors occurred, and purulent infection was now pronounced. The tibio-tarsal joint of the left side was next affected, prostration increased, the septic condition became still more marked, and at last the patient died. At the autopsy the goitre was found to consist of three lobes pretty evenly developed. The middle lobe was transformed into a purulent pouch, with fibrous walls, and contained a thick, grayish, sanguinolent matter. The other lobes were in a condition of follicular hyperplasia, with predominance of interstitial tissue. The tibio-tarsal articulation contained about a tablespoonful of greenish pus. The condition of the other organs indicated the existing septicæmia.—*La France médicale*, Aug. 25, 1880.

Sudden Death in Interstitial Nephritis.—At a July meeting of the Société Médicale des Hôpitaux, MM. Delove and Capitan presented a paper the object of which was to prove that fatal syncope may occur in interstitial nephritis. In two recent cases of sudden death at the Bicêtre, M. Delove found at the autopsies only the lesions of interstitial nephritis. Both of the sufferers had been in good health up to the time of death, which was not preceded by any morbid phenomena. A third patient had been subject to attacks of suffocation, in one of which he died. There was no trace of valvular lesion in any of these three cases, but the cardiac muscle presented sclerotic alterations. In discussing the paper M. Landouzy stated that he had made an autopsy a few days before, on a woman who had died suddenly. The brain was normal, but he found considerable hypertrophy of the left ventricle of the heart, and signs of advanced interstitial nephritis. M. Dujardin-Beaumetz drew attention to the fact that medical literature contains a number of cases of very rapid death of persons affected with interstitial nephritis, after the hypodermic injection of even very small doses of opium.—*La France médicale*, July 28th.

The Ganglionic Centres in Bright's Disease.—Da Costa and Longstreth, in summing up the researches on the state of the ganglionic centres in Bright's disease, have arrived at these conclusions:

1st. That in Bright's disease, especially in the contracting kidney, there exists a constant lesion of the renal plexus.

2d. That whilst this lesion might be looked upon as forming part of a general process of degeneration, in connection with the kidney disease, it is more probable that it is the cause of the renal malady, and precedes the degenerative changes.

3d. That the diseased condition of the ganglia furnishes the clue to the alterations of the vessels of the kidneys.

4th. That similar changes producing similar results may exist in other ganglia; for instance, in the cardiac plexus, explaining the hypertrophy of the heart.—*American Journal Medical Sciences*, July, 1880.

A Novel Mode of Treatment of Gonorrhœal Ophthalmia.—Mr. George Critchett, F.R.C.S., reports in the *Lancet* a case of gonorrhœal ophthalmia in which he had recourse to a heroic and novel method of treatment. Owing to the extreme acuteness and severity of the symptoms, the difficulty in separating the lids or exposing the cornea, and the impossibility of getting any solution into contact with the conjunctival surface, he had relinquished all hope of saving the sight, and felt justified in adopting any treatment, however severe, that promised a ray of hope. He passed a small, silver director under the upper lid as far as the edge of the orbit, against which he kept it pressed, and then with a small, sharp-pointed bistoury completely divided the lid perpendicularly as far as the margin of the eyebrow. In order to more completely uncover the cornea he separated the two angles of the divided tarsus and fixed them with fine sutures to the skin of the eyebrow. The cornea looked steamy but not ulcerated, and was buried in chemosed conjunctiva. The immediate effect of this proceeding was to diminish the redness and swelling of the lids and conjunctival membrane, and completely to expose the surface. The subsequent treatment consisted in painting over the entire surface of the conjunctiva, three times daily, with a solution of nitrate of silver—thirty grains to the ounce—and frequently cleansing and syringing with a solution of alum—ten grains to the ounce. A piece of linen moistened in this solution was kept constantly applied to the eye. This plan was continued, with gradual abatement of the symptoms, for a month; a weaker solution was then substituted. At the end of six weeks from the commencement of the treatment the eye had recovered with a perfectly bright, healthy cornea. At the termination of another fortnight the child was again placed under the influence of an anæsthetic, and the edges of the divided lids were pared and brought together with fine sutures. Good union occurred, the deformity very slight, and the lid perfectly performs its function. In the early part of the treatment the other eye was kept carefully closed with strapping so as to prevent any risk of inoculation.

Calcium Salicylate in the Serous Diarrhœas of Infants.—Dr. Alexander Hutchins recently read a paper before the Medical Society of Kings County, on the treatment of serous diarrhœas of infants by calcium salicylate (*Proceedings, September*, 1880). During the preceding three months he had treated in private practice, some twenty-seven cases of serous diarrhœa in infants, ranging from two months to two and a half years of age, using this one drug only. Some of the cases were seen but once, many only twice, and none above four times, and in all the disease is known to have been promptly and permanently controlled. No discrimination was made as to diet, which in some instances was breast-milk exclusively, in others condensed milk, the patent foods, or a mixed diet. In no case was any modification of the previous diet called for, save in the matter of quantity. All the patients were in good social and hygienic surroundings. In two instances the infants were at their summer homes, and the telegraph and mail related the symptoms and conveyed the medicine. In all cases the dose was three to five grains every two or four hours. The total quantity consumed by each patient varied between six and eighteen powders. In a few cases minute doses of aconite and veratrum were given during the persistence of high temperature, and in a few others, small doses of quinine were given after the subsidence of the disease. It was noted that the medicine seemed to have no influence in changing the secretions so as to modify the character of the evacuations. The discharges would be under control for a time, say from two to twelve hours, and the next movement would be a watery one, but there would be no further recurrence of the diarrhœa. There might be a return to normal movements, or there might be a change to a diarrhœa of indigestion, or to a diarrhœa from irritation of the mucous surface, each of which would require some special interference. These sequelæ were exceptional, and in no case did the serous discharge recur. The calcium salt had no appreciable effect on any one of the other forms of intestinal flux, whether lienteric or inflammatory, the serous diarrhœa alone seeming to be amenable to the drug. Each of the other forms required special treatment. An additional fact was noted, that the vomiting accompanying these diarrhœas was controlled as soon as the medicine began to show its effect on the discharges. Certainly, without exception, the stomach tolerated the presence of the drug.

The drug is prepared by mixing 276 parts by weight of the acid with 100 of prepared chalk, which will form 314 parts of the anhydrous salt, or, what is sufficiently correct, eleven of the acid to four of chalk, making about twelve and a half of the salicylate of clacium. It is given in syrup, or rubbed up in sugar and moistened with water, to a sufficient extent. The salicylate of bismuth has been used with success as well as the calcium salt, in the diarrhœas of infants, but it is, according to Dr. Hutchins, no better, and has the disadvantage of discoloring the discharges. It is prepared by adding 828 parts of the acid to 468 parts of bismuth oxide, which make 1242 parts of the anhydrous salt; or twelve parts of the acid may be added to seven parts of the oxide, which will make about eighteen parts of the salt.

Relation of Atropia to Opium-Poisoning.—Dr. A. Dochman, as the result of a study of a number of cases of opium-poisoning, states that between these two drugs exist an antagonism only in their action on the pupil and respiratory movements. But on the heart and brain they act independently, one rather intensifying the toxic effect of another than neutralizing each other.—*Meditz. Obozrenie*, May, 1880.

Lesions of Costal Cartilages and Ribs in Consumption.—To determine the cause of the severe pain phthisical patients complain so much of during the last stages of the disease in the region of ensiform cartilage, Dr. Kostiurin made microscopic examination of this and adjoining parts. He found periosteum and perichondrium thickened, and their vascular supply increased. Cartilages were in a state of inflammation. Softening and fatty degeneration. Tubercles were found in the marrow of the ribs. Muscular fibres of the diaphragmatic attachment to these parts were opaque and granular. These lesions determine a decrease of elasticity of the thorax, and, consequently, a diminished gaseous exchange in the lungs.—*Vratch*, 1880, No. 5.

Inoculability of Intermittent Fever.—Dr. Dochman reports a number of cases where he succeeded in inoculating the intermittent by using the contents of the vesicles of herpes labialis of patients suffering from the fever. In the first case he inoculated, on the 8th of February, a healthy man thirty years old from a boy twelve years old, with quartan. On the 11th of February the man had a full paroxysm with 30.1° C. On the 14th only malaise, without chill, with 38.3° C. In the second experiment he inoculated, from a girl with quotidian, three men. One of them suffered every evening for five days from full paroxysms, with the temperature 38.5° to 39° C.; another had only evening malaise; in the third no effect was observed. In the third experiment a girl was inoculated on 12th of April. She had paroxysms on the 14th and 16th.—*Vratch*, 1880, No. 22.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

New York, October 30, 1880.

HOSPITAL MANAGEMENT.

At present a discussion is being carried on in Great Britain regarding the proper relations which should exist between the lay and medical boards of hospitals. The immediate occasion of this is a published manifesto of the governors of Guy's Hospital concerning the nursing question in that institution. The document in question is intended to be explanatory of the course pursued by the governors and to reconcile, as is mildly intimated, any misunderstandings with the medical board. That it utterly fails in such endeavor is plainly evident by the comments of the English medical press. Without exception the governors are condemned not only for the course originally pursued in attempting to make radical changes in the nursing department of the hospital without consultation with the medical staff, but for making, under the cover of public explanation of their position, a misstatement of facts and a misrepresentation of the motives of the staff. The consequence is that the two boards are further than ever from any agreement, and, as has been boldly stated by a leading medical organ in London, the time for compromise has passed and an appeal to Parliament is necessary.

It will be remembered that a year ago the governors of the hospital determined upon making certain radical changes in the nursing department which appeared to them to be necessary. A contrary opinion held by the staff was ignored, and many so-called sweeping reforms were made in the department named, much, as was claimed by the staff, to the detriment of the hospital as a strictly medical institution. From what can be learned by an impartial investigation of the question, it seems evident that the governors not only persisted in carrying out their views without consulting the medical staff, but used the power they possessed in an arbitrary and offensively dictatorial manner. What was simply a difference of opinion on an apparently trivial matter thus in time became an actual *casus belli* between the executive and medical boards, and demanded an appeal to public opinion for the adjudication of respective rights.

The history of this difficulty is not without its lesson as applied to the government of our own charities. It is not the question of changing the methods of nursing in any given institution. This is of small importance compared with the principle involved of lay boards interfering with the rights of medical boards. Its discussion involves a decision pro or con as to whether a hospital is most useful in the capacity of an institution for the medical care of the sick or as a free hotel for the sick poor—whether medical treatment for the sick, or lay management of the institution as a mere charity, is to take the precedence. It does not seem that there could be two opinions concerning these points, and yet the misunderstandings concerning them which constantly occur between the two boards of hospitals have made up, and doubtless will continue to make up, the history of most, if not all, of the errors in hospital management. That each board has its own well-defined prerogatives is now well settled. If we admit that the primary object of a hospital is for the cure of the sick, it is safe to assume that any interference with such an object, either directly or indirectly, by the managerial boards, is, to say the least, ill-advised. Hence, in all matters of a medical character the opinions of the medical staff should be asked for and acted upon. It has been proved here that while the medical boards have no disposition to interfere with the rights of managers, they are equally jealous of their own rights. That the prosperity of the hospital, in fact all the real troubles in hospital management, have centred in what have been a violation of the latter by the governors. But in this country both boards are beginning to understand the true merits of these relations, and are preparing to act accordingly. To such an extent is this the case that it would be hard to find here a parallel to the Guy difficulty. It may be safely stated, as a rule, that no board of managers of any hospital in this or other city would presume to dictate to the medical board concerning the medical management of patients. In all matters, even of an indirectly medical or surgical character, the opinion of the physician or surgeon is as final as it would be upon a particular remedy to be taken or a particular apparatus to be applied. Hence it is now the custom to consult the medical board on the questions of sewerage, ventilation, heating, nursing, and the like. Whatever orders are given regarding the detail management of any of these matters, are subject to the appeal of the medical board, and experience has shown times without number that a proper understanding between the two boards is usually obtained without trouble.

It is easy to see, when viewing the battle of Guy's at this distance, where the mistake has been made and how easy it could have been prevented by the governors taking a very natural course in consulting the medical staff before revolutionizing a system which was really part of the medical service of the hospital. That the governors still persist in attempting to vindicate their course is an evidence that what was at first supposed to be an error of judgment, has degenerated into downright obstinacy in exercising their powers. There can be but one end to all this, and until it is reached a great deal depends upon the united stand of the medical staff.

NEW STUDIES INTO THE NATURE OF DIPHTHERIA.

Under the direction of the National Board of Health certain experiments have been recently performed by Drs. H. C. Wood and H. F. Formad with the object of discovering the nature of the diphtheritic poison. These experiments were made for the most part upon rabbits, and were intended primarily to discover whether diphtheria could be induced in those or other lower animals. This particular point was quite well settled in the negative some time ago by Curtis and Satterthwaite, whose investigations were far more extended than those which are now presented. Drs. Wood and Formad have, however, given some valuable corroborative evidence, and have added other facts which are very suggestive and which really bring us somewhat nearer a true knowledge of the pathology of diphtheria.

The first series of experiments was made by inoculating bits of fresh diphtheritic membrane in the mouth and thigh of thirty-two animals; eighteen being rabbits, the remainder cats, dogs, and a goat. Six of these animals, all being rabbits, died within about two weeks or less from the time of inoculation. Post-mortem examination discovered evidences of tuberculosis in every instance. In only one case was there any tracheal false membrane, and in this the deposit may have been due simply to a catarrhal inflammation. Micrococci were found in the blood. In no case did inoculation by the mouth cause any local or general symptoms, a fact which corresponds with the observation of Curtis and Satterthwaite, that inoculations in the cornea were entirely ineffective. The inoculations in the thigh seemed to result in the development of small, cheesy lumps. These either became absorbed, or they infected the system and caused death by tuberculosis. The rabbits, then, it is concluded, may either die very soon after inoculation of diphtheritic membrane, by absorption of a non-specific septic poison, or they may die a week or two later from a tuberculosis due to absorption of cheesy products. Most of the animals experimented on by Curtis and Satterthwaite died from the former cause, perhaps because they used larger pieces of membrane and inoculated more deeply.

It was shown by subsequent experiments that the tuberculosis was not due to anything specific in the membrane, for that disease followed the inoculation of bits of wood, glass, and wire.

So far, not much more had been discovered than was already known.

The next series of experiments was made to determine the accuracy of Trendelenburg's assertion that the introduction of pseudo-membrane into the trachea produces diphtheria. Dried diphtheritic membrane was introduced into the trachea of four rabbits. One of these died in five days. The post-mortem showed a delicate pseudo-membrane in the trachea. It was 1 mm. thick in some parts, was infested with micrococci, and showed the usual structure of natural and traumatic pseudo-membrane. The internal organs were tuberculous, but there were no bacteria in the blood. The experiments, as far as they went, confirm the statements of Trendelenburg, but they indicate very little.

A study was then made of the effects of ammonia in producing pseudo-membranous trachitis. This substance was injected into the trachea of four rabbits, a cat, and a dog. All the animals except the dog died, death generally coming on in two or three days. False membrane was observed in the trachea of all six animals, and tubercles were also uniformly present in the internal organs. Furthermore, contrary to the statements of Oertel, bacteria and micrococci were in every instance found in the traumatic false membranes. The experiments seemed to show that diphtheritic membrane placed in the trachea will produce a fatal pseudo-membranous trachitis, although the same membrane inoculated in the thigh will not cause death, except indirectly, by exciting caseous foci and a resulting tuberculosis. This point, as stated by the experimenters, needs a further study.

A fifth set of experiments showed that other foreign bodies, such as slough, inflammatory products, and pus, will also produce a pseudo-membranous trachitis. So that the conclusion is almost certain that such trachitis is not a specific process, but is only an intense inflammation such as any highly irritant body may excite.

As a general conclusion, then, it is stated that the contagious material of diphtheria is really of the nature of a septic poison which is also locally very irritant to the mucous membranes; so that when brought in contact with the fauces and nose it produces an intense croupous inflammation simply by its local action, and without any absorption. But further, though it may sometimes thus act locally and directly, it may also bring on the angina by being first absorbed, then acting locally by being carried in the blood to the mucous membrane of the throat. Under this theory, again, it is possible that the poison may cause a purely local angina, no absorption occurring; or, on the other hand, a simple local nonspecific trachitis may end in adynamic diphtheria in consequence of absorption of septic material.

In regard to the relation of bacteria to the disease, it is stated that it seems altogether improbable that they have any connection with it whatever. There is, however, the possibility that the bacteria may act upon the exudations of the trachea as the yeast plant acts upon sugar, and cause the production of a septic poison which differs from that of ordinary putrefaction, and bears such relations to the system as, when absorbed, to cause the systemic symptoms of diphtheria.

These views in regard to the nature of the diphtheria poison have a good deal of the hypothetical about them, and are, indeed, only put forward tentatively by their authors. The experiments of Dr. Wood and Dr. Formad are very instructive, but perhaps in no direction more than in showing where further investigation is needed. It is to be hoped that the National Board of Health, whose bulletins have heretofore been somewhat meagre in scientific matter, will see that the present work is continued.

Reviews and Notices of Books.

On the Bile, Jaundice, and Bilious Diseases. By J. Wickham Legg, Fellow of the Royal College of Physicians of London, etc. 8vo, pp. 719. New York: D. Appleton & Co. 1880.

The practitioner who has come to the conclusion that very little of value can be said of the bile or the diseases with which it is associated, will be somewhat astonished at the size and contents of the present work. Considering the subjects treated, and the necessity for positive knowledge concerning them, he is, at first, willing to condone the infliction of such a large volume and such an elaborate treatise, but after wading through the larger number of chapters, and arriving at "conclusions in which nothing is concluded," he naturally wishes that the work was half its present size, and was of a more practical character. Saying thus much, it is due to the author to state that the work shows great research, laborious consultation of authorities, and careful study of the results of experiments upon the complex fluid. That very few practical deductions are made is due more to the abstruseness of the subject itself than for any lack of painstaking on the part of the author. In a word, then, the practitioner who takes up this work for the sake of any aid that it may afford him in the treatment of diseases of which jaundice is a symptom will be much disappointed. To the physiological chemist the case will be entirely different, for such will find a very complete review of the chemistry of the bile, and what is known of its physiological properties. Concerning the latter point, in view of the expressed uncertainty whether the liver be a mere filter, or if it secrete the bile itself, it would appear that some further investigations are called for. The same may be said concerning the direct influence of the ingestion of food and the quality and amount of the latter, the influence of nervous excitation, the real offices of the fluid, and the causes of its absence in the fæces in certain pathological conditions. Concerning the latter point our author maintains that it cannot be looked upon solely as an excrement, for it has been seen that deep changes in nutrition have followed its diversion from the body; that there is no evidence that it is necessary for the process of digestion, or for the purposes of a purge; that it has any special power in arresting putrefaction; and that it is capable of neutralizing the acid of the chyme. In fact, the only offices which are not positively disputed to it are the emulsifying of fats and the changing of starch into sugar. What we do not know has been proven by very careful and numerous experiments, and it is, perhaps, comforting to imagine that so far we have made a good beginning. The action of various drugs upon the bile is given in much detail, and is a careful summary of the experiments of Rutherford, Scott, Rohrig, and others. The usual practical guides to the presence of bile in the fæces not being reliable, according to our author, much of clinical experience regarding the action of so-called cholagogues goes for naught. For instance, Dr. Legg maintains that the absence of color in the fæces is not, as a rule, due to the absence of bile, and that the presence of the latter can only be determined with certainty by chemical examination.

In the portions of the work in which the diseases of which jaundice is a symptom are treated, the author has expended much labor and research, but in the general arrangement of his subjects he has reversed the general order by giving precedence to the symptom and its treatment. And yet, in the last chapter, he suggests that the term bilious diseases be entirely abolished. But the faulty arrangement does not detract from the otherwise valuable material presented under the different pathological conditions associated with jaundice.

Under these heads we have presented to us a very exhaustive account of the symptoms and pathological anatomy of acute yellow atrophy, of the jaundice of yellow fever, the icteric conditions associated with phosphorous, antimony, arsenical, and other poisonings; also the jaundice of pregnancy, of the fœtus, of the new-born, etc. The work concludes with a copious bibliography, which is particularly rich in references to the literature of acute yellow atrophy. The work is well printed, and is gotten up in the usual good style of the publishers. The paper is fine, the typography excellent, and the chromo-lithographs and engravings are well executed.

A Treatise on the Practice of Medicine, for the Use of Students and Practitioners. By Roberts Bartholow, M.A., M.D., LL.D., Prof. Mat. Med. and General Therapeutics, Jefferson Med. College, Philadelphia, etc. 8vo, pp. 853. New York: D. Appleton & Co. 1880.

In a work such as the one before us there are many points to take into consideration in estimating its value as a text-book for students and practitioners. But, considering its varied contents, these points can only be discussed in a general way. It may be said in the beginning that the work is of a thoroughly practical character, which fact will account for, or rather excuse, its almost comparatively small size. It would appear that everything is sacrificed to brevity and condensation of such facts in clinical history, pathology, and therapeutics as may serve the purposes of one who desires to get at a practical point by the shortest and surest route. To accomplish such a result not only involves a vast amount of study, research, and experience, but a faculty for bringing out the salient points, and presenting them in an intelligible and practical form. That Professor Bartholow is peculiarly qualified for such a task the present work fully attests. The discussion of any extraneous matters is omitted, as is also the reference to theories to explain this or that symptom, pathological condition, or therapeutical result. The division of subjects is natural, because anatomical in character. Each apparatus is taken up in turn, the various diseases described as to etiology, diagnosis, and treatment. In perusing the work, the reader cannot fail to be struck with the appreciation on the part of the author of the wants of the practitioner. This is apparent not only in referring to the pathology and treatment of the disease, but more particularly to its symptomatology, giving a pathological reason for the latter which serves to fix it in the mind of the reader. The diagnosis of disease is studied with particular care, and no pains are taken to present in the smallest space the necessary points to be taken into consideration in arriving at a conclusion. In some of these respects it resembles Da Costa's Medical Diagnosis, which, so far, is giving it the highest praise.

As might be anticipated, our author is a therapeutist in every sense of the word. But in his efforts to prove that medicines are of value in the treatment of disease, and that some are almost specific in their action, his enthusiasm sometimes gets the better of his judgment. Still the end so much justifies the means that no candid reader will call him to account. The new departure at this time is particularly desirable, and will tend to turn the attention of the profession to the more thorough and comprehensive study of the science of therapeutics.

The work as a whole is peculiar, in that it is stamped with the individuality of its author. The reader is made to feel that the experience upon which this work is based is real, that the statements of the writer are founded on firm convictions, and that throughout the conclusions are eminently sound. It is not an elaborate treatise, neither is it a manual, but half-way between; it may be considered a thoroughly useful, trustworthy, and practical guide for the general practitioner.

A New School Physiology. By Richard J. Dunglison, A.M., M.D., Editor of Dunglison's Medical Dictionary, etc. 12mo, 314 pp. Philadelphia: Porter & Coates.

This is a well arranged, comprehensive manual of physiology, and cannot fail to meet with the wants of teachers and scholars. The author has used good judgment, not only in the selection of his subjects, but in their intelligible and popular presentation.

On Slight Ailments: their Nature and Treatment. By Lionel S. Beale, M.B.F.R.S., Fellow of Royal College of Physicians, etc. 12mo, pp. 353. Philadelphia: Presley Blakiston. 1880.

The title of this little work is quite novel and taking. It cannot as such fail to recommend itself to the attention of the medical public. If it is destined to fulfil the expectations that it would naturally create, it will invite attention to an entirely new department of study, a study which is very much neglected. Fully fifty per cent. of all the cases that the physician is called upon to treat are comparatively trifling in character; that is to say, are such as do not particularly endanger life, or invite a permanent derangement of health. Hence the prescriber treats them with more or less indifference, and dismisses the patient without caring to give him much satisfaction or treatment. But there is ofttimes more skill to be shown in the satisfactory treatment of these ailments than is generally imagined. A slight dyspepsia, a teasing neuralgia, a bad breath, a persistent muscular pain, and a headache are just as legitimate subjects for treatment as pneumonia, Bright's kidney, dysentery, or typhoid fever. It is safe to say further that many times more reputations are made and unmade, as measured by the skill in treating what are called trifling ailments than is usually believed to be the case by general practitioners. Prof. Beale's little work furnishes a very efficient means to that end, treating as it does of the diseases which are of common occurrence, and on that account supposed to be of no importance. The reader who peruses the work will be impressed with the necessity of studying the slightest departure from the healthy standard, and thereby preventing serious maladies. Its table of contents will give a fair idea of the scope of the manual. After a suitable introductory, the state of the tongue in health and slight ailments is considered, after which are likewise treated in turn the conditions of appetite, nausea, thirst, hunger, indigestion, constipation, diarrhœa, biliousness, sick headache, neuralgia, rheumatism, feverish states, and common forms of slight inflammations. All these subjects are well considered, and will well repay a careful perusal.

A Manual of Minor Surgery and Bandaging. By Christopher Heath, F.R.C.S. Sixth edition. Philadelphia: Lindsay & Blakiston. 1880.

This edition of "Heath's Manual" has been somewhat enlarged and revised. It now contains 115 illustrations, and, as far as its text is concerned, very effectually covers the field usually occupied by works of its class. The descriptions of the various minor operations are to the point, and are, by aid of the illustrations, made perfectly intelligible to the merest tyro. Its standard has been fixed for the requirements of the house-surgeon in a large hospital, and is maintained throughout the work. For obvious reasons it is peculiarly fitted for the wants of the general practitioner who is called upon to do ordinary surgical operations.

The Ocean as a Health Resort: a Handbook of Practical Information as to Sea Voyages, for the use of Tourists and Invalids. By William S. Wilson, L.R.C.P., Lond. 12mo, pp. 260. Presley Blakiston. 1880.

This is a readable book, written in a popular style, and, as its title indicates, giving some practical hints concerning life on the ocean. The remarks are based on the incidents of a voyage to Australia, and much practical information is given under the following headings: curative effect of ocean climate; various health voyages, such, for instance, as those to West Indies, Brazil, Cape of Good Hope, India, Suez Canal, etc.; choosing a ship; life at sea; climate; weather; objects of interest at sea; climate of Australia; South Africa and its climate; and the meteorology of the ocean. Appended are some directions concerning the necessary outfit, and a chart showing the ocean routes and illustrating the physical geography of the sea. The author gives ample evidence of being practically familiar with his subject, and has written for the travelling public a very useful manual.

The Pathology, Diagnosis, and Treatment of Diseases of Women, including the Diagnosis of Pregnancy. By Graily Hewitt, M.D. Third American from Third London Edition. Revised and enlarged. With One Hundred and Thirty-two Illustrations. Philadelphia: Lindsay & Blakiston. 1880.

Dr. Hewitt is perhaps the best representative of English gynecology, and his name, as the author of this book, gives assurance that its contents deserve attention, even though they are now eight years old. The last London edition of this work was printed in 1872. Still, in most departments, the views therein expressed have not been superseded, and the book is to be criticised more for what it lacks than for any errors it directly conveys. The author belongs to the mechanical school of uterine pathologists, putting displacements, flexions, etc., as the initial point of most of the morbid changes. His views are just, so far as they go, but he fails to appreciate at all the pathogenetic importance of lacerations of the cervix and of the perineum. His methods of treating displacements are essentially in accord with those of the best American gynecologists, and need not be further criticised. In regard to gynecological surgery, however, Dr. Hewitt is far behind his American compeers. He is not only unsatisfactory in describing the operations, but he does not give all those that have been introduced at the present day. We instance the fact that cystotomy for cystitis is not referred to at all, so far as we can find.

The book is written in a pleasant and readable style. It will form a very useful addition to the library of the specialist, but it is quite insufficient for the beginner, who wishes to ground himself in modern gynecological science.

A Treatise on the Common Forms of Functional Nervous Diseases. By L. Putzel, M.D. New York: William Wood & Co. 1880. "Wood's Library of Standard Medical Authors."

In the preface to this work the author states his belief that pathological anatomists have now done nearly everything possible to discover the lesions in the diseases of which he writes. They have signally failed so far, and it is highly improbable, he says, that they ever will succeed. The changes at the root of the so-called functional diseases are molecular, and if ever their exact nature is discovered, it will most likely be through the balance of the chemist. It is perfectly legitimate, therefore, we are told, to use the term "functional disease," and it is wiser just now to pay more attention to the clinical study of this class of affections, as being much more likely to produce satisfactory results.

These are bold views to express at a time when pathological anatomy is being studied with so much enthusiasm. That they are sensible and true, however, we confidently believe, and the valuable character of the present work gives a solid support to the judgment of the author in asserting them.

The four classes of diseases treated of by Dr. Putzel are, chorea, epilepsy, neuralgia, and peripheral paralyses. In each the clinical history is made a prominent feature. On all the subjects the author shows a complete familiarity with neurological literature, while he adds no little original matter from his own experience.

The section on chorea is, perhaps, the most perfect of the four. It is, indeed, the model of a practical monograph, and forms the best short presentation of the subject that has been given. No one, of course, can discuss the pathology of chorea without subjecting himself to criticism; nor will Dr. Putzel be an exception. He discredits the value of pathological anatomy as affording any light to the seat or nature of the lesion in this disease, and he gives support to the theory of the malnutrition of the cortical ganglion cells as affording the most satisfactory explanation of its pathology. No theory, however, should be considered at all complete or satisfactory which ignores the facts of the close relations often existing between hemichorea and embolic hemiplegia, or of the anatomical fact of the extremely frequent existence of vegetations upon the valves of the heart.

The chapters on epilepsy are excellent ones. They contain, besides descriptions of the different forms of the disease, the records of cases illustrating certain rare clinical features, such, for instance, as the persistence of consciousness during an epileptic attack. The author favors the "explosive" theory of Jackson to explain the nature of the disease. The chapter on treatment is rather meagre.

The section on neuralgia does not call for special comment, except, perhaps, in regard to the part devoted to treatment. Dr. Putzel is inclined to be pessimistic as to the efficacy of drugs. He parades no panaceas, and announces no wonderful specifics. Additional confidence can therefore be given to those measures which are recommended.

Strychnia and galvanism are strongly endorsed in sciatica, and aconitia in trigeminal neuralgia. We find no mention of croton chloral or of tonga, and very little is said regarding nerve-stretching. Morphia is referred to with little favor. The section, on the whole, is vastly superior to the last work upon this subject by Dowse.

The chapters on peripheral paralysis are especially valuable, because they contain descriptions not found in works on general medicine, nor to any full extent in English works on diseases of the nervous system. The subject is treated here as completely as possible in a practical work. We are unable to see, however, by what authority he classifies inflammations of the nerves among functional diseases.

We regret that the author could not include some of the other than "common" functional nervous diseases in his work; nor do we see how he could justly exclude such diseases as hysteria, migraine or writers' cramp. What the author has done, however, he has done more than well, and it would be hypercritical to find fault for what the book has not.

Transactions of the State Medical Society of Arkansas. Fifth Annual Session, May 5, 1880.

This is a modest-looking volume, but it contains a number of interesting papers. One of the most important is that by Dr. J. H. Southall on "Expert Testimony without Compensation." In this the author relates the history of a case in which he vindicated the right of the physician to refuse to testify as an expert under pay as an ordinary witness. A novel case is that reported by Dr. Thos. W. Hurley on "Septicæmic Poisoning and Mercurial Eczema Caused by Wearing Vulcanite Plates."

Health and Healthy Homes: A Guide to Domestic Hygiene. By George Wilson, M.A., M.D., etc. With Notes and Additions by J. G. Richardson, M.D., etc. 8vo, pp. 314. Philadelphia: Presley Blakiston. 1880.

The author has endeavored, in this work, to place before the laity the subject of hygiene in a practical and concise manner. All the topics treated of are well worthy of perusal, especially the chapters on the "Causes of Disease," "Food and Diet," "Cleanliness and Clothing," and "The Home and its Surroundings." The book is gotten up in a creditable manner, and will prove of inestimable value to those who are interested in the care of families, as well as to others who wish to gain a knowledge of a subject about which so little, comparatively, is known.

Reports of Societies.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, October 7, 1880.

FORDYCE BARKER, M.D., LL.D., PRESIDENT, IN THE CHAIR.

AFTER the reading of the minutes, the Librarian, Dr. Laurence Johnson, reported that 202 bound and 29 unbound volumes, 535 medical journals, and 245 medical pamphlets had been received since the last meeting.

The Corresponding Secretary, Dr. John G. Adams, announced the death of Alfred Swayne Taylor and Wm. Sharpey, of London, Francis Richley, of Italy, Paul Broca, of Paris, von Hebra, of Vienna, and C. D. Jackson, of Boston.

The Chairman of the Committee on Admissions, Dr. Mark Blumenthal, recommended the election of the following gentlemen as Corresponding Fellows: Philip S. Wales, Surgeon-General of the U. S. Navy; Gaetano La Loggia, of Palermo, Italy; and Frederick D. Lente, of Florida. They were unanimously elected.

THE AIR WE BREATHE AS AFFECTING HEALTH

was the title of a paper that was then read by DR. FRANCIS V. WHITE, who first referred to the composition of atmospheric air as found without and within buildings. Bad air, according to Angus Smith, contained 20.06 of oxygen, and an atmosphere that could be endured for only a short time, according to the same author, contained 17.20 of oxygen. The maximum proportion of ozone was stated to be $\frac{1}{700000}$ part of the bulk, and the chief source of that constituent was atmospheric electricity. Ozone was more abundant during the night than in the day; more in winter than in summer; and least in damp, foggy weather. The author of the paper then referred to the purity of the atmospheric air at different heights, from six to forty feet, and showed how the character of the strata could be modified by winds, etc. He then passed to the consideration of the atmospheric air within buildings, and dwelt at some length upon the deleterious influence of ground-air and the methods that had been proposed for giving us immunity from its evils. Reference and quotations were made from Dr. Stephen Smith's writings on hospital organization in that connection, and special mention was made of the heated shaft, with openings at various depths, as the proposed means for removing the evil influence exerted by ground-air.

The sources of impure air within dwellings were then noticed, such as vegetable and other substances in the cellar in an improper condition, the advent of sewer-gas, the use of carpets which become loaded with dust and all sorts of impurities, and when stirred or unloaded, fill the atmosphere with deleterious particles.

Another source of vitiated air within buildings was combustion from artificial lights, and some interesting analyses of the air in theatres were given.

The question of ventilation was considered under three heads: 1, natural, by means of doors, etc.; 2, aspiration, by means of chimneys, etc.; and 3, propulsion, by means of fans, etc. A somewhat extended reference was here made to the writings of Dr. John S. Billings on this subject, who regarded the question of heating and ventilation as still problematical—that is, so that all parts of each room, at all times, shall be as free from dangerous impurities and perceptible odors as the external air, without causing discomfort to the occupants. irrespective of the dryness or moisture of the external air. The author of the paper accepted the fan plan. He then passed to the consideration of the varieties of heating apparatus, such as fireplaces, steam radiators, furnaces, stoves, cast and wrought iron, and pointed out the advantages and disadvantages which each possessed.

For proper ventilation there must be ingress and egress of air.

The question of air-supply was then discussed, and the conclusion reached that it should be taken between six and forty feet from the ground, and that it should be screened and conveyed through conduits made of proper material to which ground-air could not have access.

A preference was expressed for wrought-iron instead of cast-iron furnaces, because of the porosity of the former.

The author's decided preference, however, was in favor of heating with clay heaters which have three chambers: 1, for the reception of cold air—below; 2, for combustion—between; and 3, for the hot air—above. The quality of the heat was moist and mild, and usually the water-pan was not needed. One advantage which the clay had over water was its power of retaining heat for several hours after the fire had gone out. Steam and hot water, however, were regarded as acceptable methods of heating, where expense was not a barrier.

THE PRESIDENT asked for an expression of opinion concerning the influence of gas-stoves, and the "sham wood fires" so frequently seen in fireplaces (gas made to present the appearance of a wood fire), and called upon Dr. Janes to open the discussion.

DR. E. H. JANES, after complimenting the noteworthy departure from custom which the Academy had made by giving opportunity for discussing a topic belonging to preventive medicine, remarked that, in his opinion, heating rooms with gas-stoves was the least desirable method, and was injurious, because it was next to impossible to provide a sufficient amount of ventilation to get rid of the products of combustion constantly being discharged into the room. He would not, however, say the same concerning "sham fires;" for, he thought if they were placed well within the fireplace so as to be subject to the draft of an open chimney, no harm would follow their use. The subject of the paper was an important one, because it was an accepted statement that poisons entered the human body through these channels: 1, food; 2, water; and 3, the air we breathe, and he believed it safe to conclude that, in the majority of cases, the offending material entered with the inspired air, hence the importance of as nearly absolutely pure air as possible for breathing purposes. He agreed with Dr. White with reference to the deleterious influence exerted by ground-air, and the danger to which we were exposed unless our cellars were properly protected against the exhalations constantly rising and constantly being drawn into our houses, especially during the seasons when furnaces in the cellar were heated. He believed it to be possible, however, to have cellars so thoroughly cemented as to prevent the ingress of ground air.

With reference to ventilation Dr. Janes thought that if advantage was taken of the principle of hot air ascending and cold air descending, the waste heat in our buildings could be managed so as to ensure proper ventilation. Ventilation, however, was not confined merely to the getting rid of a certain number of cubic feet of vitiated air, and supplying its place with a certain number of feet of pure air, but the regulation of the degrees of moisture of the atmosphere was an important factor. He did not believe that air was deprived of any of its moisture by coming in contact with hot iron furnaces; it was simply warmed, and its capacity for holding moisture increased, therefore, only relatively dry. But we felt that it was dry and irritating and uncomfortable unless a certain amount of moisture was added.

He did not agree altogether with Dr. White in regard to heating by radiation; but considered it as the most healthful method of warming a room. One of its disadvantages was its expense. One great advantage was that it warmed the body without heating the air, and air which had not been heated was more healthful than that which had been subjected to heat.

The imperfect combustion of coal in heating furnaces gave rise to a large quantity of carbonic oxide, which was a *direct* poison; and which more or less passed through *cast iron*, when heated to redness, and thus existed in the air as a direct poisonous constituent. Iron furnaces should be sufficiently large not to require red heat. One advantage of the clay heater was its large surface, thereby avoiding the necessity of raising it to so high a degree of temperature as was usually necessary with the stove or iron furnace. He thought that heating by means of water-pipes had the same advantage that clay heaters did, namely, were slowly heated and retained heat for some time after the fire was extinguished. With reference to the steam coil, it was very liable to become dusty, and, therefore, objectionable, as Dr. White had remarked, but otherwise, and if kept clean, he thought there was no serious objection to it as a means of heating buildings.

Dr. O'Sullivan spoke with reference to the improper ventilation of churches and school-houses, and of the necessity of avoiding ground air. As an illustration of how little attention was paid to the matter in the construction of public buildings, he cited a case in which a *new* public school building had one-half of its cellar flooded with water, and the board of managers had no idea of the exact condition of affairs.

Dr. Janes thought it essential to test the air with a hygrometer before reaching any conclusion concerning the amount of moisture it contained.

Dr. A. C. Post introduced resolutions complimentary to Dr. Henri Nachtel, who was chiefly instrumental in establishing "The Medical Night Service," and they were unanimously adopted.

On motion by Dr O'Sullivan, they were referred to the medical and the secular press for publication.

Dr. John G. Adams, on the part of the contributors, presented to the Academy a portrait of Dr. H. D. Bulkley, late president (1870-'71). His remarks were seconded by Dr. Frank H. Hamilton. The Academy then adjourned.

OBSTETRIC SECTION.

Stated Meeting, September 23, 1880.

Dr. Salvatore Caro, Chairman.

DEMONSTRATION OF POULLET'S OBSTETRIC FORCEPS, WITH GENERAL REMARKS UPON THE PROPER USE OF FORCEPS AT THE SUPERIOR STRAIT.

Dr. Josef Kucher read a paper and made the demonstration above indicated. The principle illustrated in Poullet's instrument was essentially that upon which Tarnier's forceps operates, with the addition of an apparatus for regulating and determining the amount of traction force applied. To illustrate, take an ordinary pair of long forceps, pass a strong cord or tape through each fenestra (in Poullet's instrument there is a hole for this purpose in shank of the blade, just below the fenestra), bring the ends out and tie them around a pivot attached to a button which is moved forward or backward by a thumb-screw at the end of a long iron bar that terminates in two padded feet which press against the inner surface of the thighs of the woman.

The author of the paper doubted whether either Poullet's or Tarnier's instruments would ever come into general use while so much could be accomplished by an intelligent use of forceps long and favorably known to the profession. (The application of Poullet's forceps was demonstrated on a manikin.)

Dr. T. G. Thomas remarked that he had but little to say concerning the forceps exhibited, for the reason that it was of doubtful utility to discuss the use of an instrument the practical action of which we know little or nothing. There were two fields in which to demonstrate obstetrical instruments: 1, on the manikin; and 2, in the lying-in chamber, on the living woman. However prettily an instrument might fit the manikin fœtal head and draw it through the passages of a manikin body, it could not be argued therefrom that it would operate equally satisfactorily upon the living woman. He thought the opinion expressed by the author of the paper, with reference to the use of forceps, were those which were generally accepted by obstetricians in this country. There was one point to which he wished to direct attention, and it was that in deformity of the pelvis the forceps were very frequently applied too early. He had seen the forceps applied and the most strenuous efforts made at effecting delivery fail. The instruments were then removed, and in the course of a few hours reapplied, when a delivery that was impossible before had become much easier from the fact that during the hours of waiting the labor-pains had been moulding the head of the child, its shape had become conical, etc., so that it entered as a wedge into the contracted pelvis.

Another point was as to *when* the forceps should be applied. He believed that the rule, when the head of the child was at the inferior strait or in the cavity of the pelvis, was entirely different from that which belonged to the use of the forceps at the superior strait.

If the head was within the pelvis or at the inferior strait, the forceps should always be applied with reference to the child's head, not with reference to the pelvis of the mother; and for the reason that the operator could choose the short diameters of the head, put them on where the pelvis was not occupied, and deliver with greater advantage than by doing otherwise.

But delivery from the superior strait was an entirely different question. In most instances the necessity arose from deformity of the pelvis, and when such was the case, delivery should be attempted only with special reference to the diameters of the entrance to the bony canal. He thought that, when Dr. Barnes insisted that in delivering from the superior strait the forceps should be used with reference to the pelvis, that he was in accord with Smellie's original idea in the construction of the long forceps; for they were constructed with reference to that very fact, and not with reference to the head of the child. Again, in probably ninety-nine out of one hundred cases we were uncertain as to the degree of the deformity of the pelvis. The measurements of the pelvis were very imperfect indeed. Let it be supposed, for example, that the obstetrician was uncertain with regard to the extent of the deformity: he thought it was safe and good practice to watch the woman carefully, taking into consideration her general condition, the condition of the soft parts particularly, and not interfere until the necessity was manifest. With reference to the application of the forceps, he thought that a great mistake was made if they were used with the idea that they must be adhered to throughout the case. The obstetric forceps should be applied as a tentative measure. A moderate or full degree of force might be applied, but after such, and the head not descending, the forceps should be displaced by some other method, and one of two others the obstetrician might adopt:

First, if the head was perfectly movable, *version.*

Second, far better than either the forceps or version, if the head was immovable, was the operation of craniotomy.

Dr. Isaac E. Taylor believed that the forceps, in a case of contracted pelvis at the superior strait, must always be applied to the sides of the pelvis, and that they could never be applied over the ears, as had been claimed to be possible by some writers. He believed it to be impossible to apply the forceps directly antero-posteriorly under such circumstances, as had been claimed by some gentlemen in Philadelphia.

Again, he thought he had never seen the forceps applied to the child's head in the cavity of the pelvis.

With regard to *force*, he believed that there was no necessity for it in forceps delivery. He believed in what he called the "relay treatment;" that is, the application of the forceps, gently holding the head in contact with the internal os, changing the direction of the expulsive force if necessary, etc., for ten, fifteen, or twenty minutes, and if not much advancement was made, remove the instruments, and, for a time, allow Nature to manage the case. Then reapply the forceps, and in most cases it would be found that a moderate amount of traction would cause the head to descend much easier than before. In that way the instruments might be reapplied several times; and finally, he never completely delivered the woman with the forceps. He contended that an intelligent operator was as capable of judging concerning the amount of force to be expended as was the instrument offered by Tarnier in its modification by Poullet. The fact was that all obstetric operations must be tested at the bedside of the woman, where a living manikin was to be operated on and two lives were to be saved. He regarded Dr. Thomas's remarks as entirely proper with reference to version in case delivery could not be effected by the forceps; but he thought that it could be accomplished by *external* version. He has not introduced his hand into the uterus for that purpose over three times during the last thirty years.

He thought that craniotomy should, as much as possible, be avoided. Dr. Taylor then related the history of cases illustrating the value of the "relay treatment."

Dr. Studley exhibited a modification which he had made of Tarnier's forceps.

Dr. Kucher remarked that Tarnier had made six modifications of his own instrument, and, curious enough, his *first* modification was exactly that offered by Dr. Studley.

Dr. S. T. Hubbard referred to three cases, interesting, with reference to modes of treatment:

In the *first*, Dr. Taylor in consultation, attempt at delivery with forceps failed. Version was performed, and a living child was the result.

In the *second* case, Dr. Taylor in consultation, the use of the forceps was unsuccessful. Craniotomy was performed. The mother lived. The same woman became pregnant again, and was delivered without assistance, and there was not much difference in the size of the children.

In the *third* case, Dr. Taylor in consultation, the forceps were applied *three* times, and the woman was delivered with safety.

The Chairman remarked, with reference to the time *when* the forceps should be applied, that after Nature had ceased her efforts art must come to the aid of the mother, but the delay must not be too great.

Correspondence.

RAPID LITHOTRITY.

BIGELOW'S METHOD—DEATH FROM SUPPRESSION OF URINE.

To the Editor of The Medical Record.

Sir:—I wish to put on record a synopsis of a fatal case of lithotrity, hoping that before long the statistics of this operation will enable the profession to pass a verdict upon its merits as compared to lithotomy.

August 25, 1880, a gentleman, æt. 70, resident of Alabama, consulted me concerning some trouble with his bladder. For six years just previous he had suffered from occasional attacks of cystitis and had passed at various intervals of this time a dozen urinary calculi, the largest of which measured about one-quarter of an inch in its longest diameter.

I sounded him and discovered a stone about one inch in diameter. Within the last few months his suffering had been much increased. He was prostrated from loss of sleep and the intense pain experienced in micturition, which act was necessary during every hour or two of the twenty-four. He was consuming about four grains of opium a day. The urine was loaded with pus and contained considerable blood. No casts. A slight amount of albumen was present, due to *liquor puris*, which always contains this substance.

For two weeks I prepared the patient for operation by tonics, diet, and gradual dilatation of the urethra. His condition improved considerably, and in consultation with Professor E. L. Keyes and Dr. E. A. Banks, who rendered me very valuable assistance, the operation was performed on September 14th.[*] The etherization and operation lasted fifty minutes.

---

[*] I am also under obligation to Drs. Cramer and Ayers for the service rendered as assistants.

Four separate crushings and washings were made. The stone measured a fraction more than one inch in the grasp of the lithotrite. The instrument used was Professor Keyes' modification of Sir H. Thompson's crusher, and the exhausting apparatus was Thompson's. The largest tube (18 American) filled the urethra tightly. The stone, as the autopsy proved, was thoroughly removed without any injury to the bladder. The patient rallied well from the operation, talked rationally, and passed his urine several times in small quantities during the first six hours. A few hours later his water ceased to flow, he became delirious and vomited a small quantity of dark-colored fluid. The vomiting was explosive in character and indicated uræmia. In order to be sure that there was no retention, I introduced a small soft catheter into the bladder and drew off about two ounces of bloody urine, at the same time washing the bladder out with a three per cent. carbolic acid solution. The uræmia persisting, I administered a ʒ jss. fl. ext. jaborandi per rectum, which produced profuse perspiration and relieved these dangerous symptoms for the time. In consultation with my friend Dr. E. A. Banks, it was determined to attempt a restoration of the functions of the kidneys by the use of infusion of digitalis and citrate of potas. As soon as the patient was brought under the influence of this mixture the urine flowed in fair quantity, but incontinently. Chloral and morphia were given when necessary to relieve pain. He was fed on iced milk with a small quantity of whiskey added, at intervals and in fair quantity. Despite every effort the patient sank in a comatose condition and died eighty hours after the operation.

With the assistance of Drs. Banks and Edward Ayers I made an autopsy sixteen hours after death. A careful examination of the bladder showed this organ positively without an injury. There was evidence of the cystitis which had long existed. The third lobe of the prostate, which stood up in front of the internal orifice of the urethra, was slightly bruised by the passage over it of the exhausting tubes; but this injury was trifling in extent and not worthy of consideration as a factor in the fatal result. There were a half-dozen sand-like particles of the stone at the neck of the bladder, all of which would have easily passed *per urethram* with the first forcible act of urination. The condition of the mucous membrane of the bladder proved that it had not been "caught up" by the lithotrite. In the prostatic follicles were found embedded twelve small calculi, which had undoubtedly formed in these follicles. The longest of these was about one-sixteenth of an inch in diameter.

The left kidney showed two cicatrices, most probably the remains of quite recent abscesses. In the pelvis of this organ and in the interpyramidal substance was a quantity of extravasated blood. The right kidney was intensely congested, as in acute desquamative nephritis.

It was concluded that the cause of death was suppression of urine and uræmia, resulting from the shock of lithotrity, the shock resulting from urethral distention rather than from irritation of the bladder.

In summing up this case it may be said that, in justification of the unsuccessful issue:

1. The patient was over seventy years of age. 2. Had suffered from the disease at intervals for six years past, and constantly and severely for over a year just preceding the operation. 3. Had had old kidney trouble. 4. Had twelve calculi in the substance of the prostate.

As against the result: 1. Despite his advanced age and long sickness, he was thought to be in good enough physical condition to stand lithotrity without much danger. 2. He was calm, philosophic, courageous and hopeful. The stone was of small size.

John A. Wyeth, M.D.

Oct. 4, 1880.

ASYLUM MORTALITY AND NON-RESTRAINT.

To the Editor of The Medical Record.

Sir—In the Record of October 16th appears an item headed "Asylum Mortality and Non-restraint," in which is noted a diminishing death-rate in the County Asylum of Lancaster, England, and the fact is explained solely by the abolition of mechanical restraint. Scoffers might laugh at this exegetical feat, but the humble searcher after truth would rather ask a question. At my elbow lies a tabular statement of the ratios of deaths to the average numbers under care during the year 1876, in ten asylums—all located within the narrow limits of New England—as follows: at Augusta, Me., 13.07 per cent.; at Concord, N. H., 10.00; at Brattleboro, Vt., 5.82; at Worcester, Mass., 15.40; at Taunton, 10.24; at Northampton, 7.80; at Somerville. 12.50; at Providence, R. I. (Butler Hospital), 8.27; at Hartford, Conn., 6.76; at Middletown, Conn., 6.69. Now, here is presented a mortality varying considerably, and at several places as low as at Lancaster. But in all these institutions mechanical restraint is advantageously used like any other therapeutic measure on the physician's prescription. Will some one explain these figures on the "abolition" theory?

Querist.

MALARIAL MANIA.

To the Editor of The Medical Record.

Sir—In a recent issue of the Medical Record I notice a correspondent has ventured to deny that malaria is the cause of all disease to which humanity is heir. I am glad to know that one member of the profession has the brain to see and the courage to talk against this assumption of human ignorance. When I commenced the practice of medicine, thirty-five years ago, the liver was the only organ noticed in the human body, and calomel the only remedy. Now malaria is the source of all our woes and quinine the antidote.

Being an old doctor, I am frequently called in consultation by the younger members of the profession, and for the last ten years I cannot call to mind a single case of any disease, from a stone bruise to a broken neck, in which the doctor had not given quinine. These doctors tell me the books recommend us to do so and so. Before a man writes a book he is just a common doctor like the balance of us; but as soon as he gravely writes his opinions down in a book they become as the voice of inspiration.

Not long since I read an article at one of our county medical societies against the use of quinine in pneumonia. I said that if there was no more quinine used in the treatment of disease than was necessary, that quinine would not be worth a dollar an ounce. Well, my brethren said I was a heretic.

There has been an epidemic here, during the last few days, among children. They had a fever, attended with a cough, and the disease ended in about seven days.

My professional brethren all gave quinine, they said it was malaria, and the patients all got well. I could neither see nor smell the malaria, so I gave no quinine, and my patients all recovered also. Of course it was all malaria.

There has been in this vicinity an epidemic of typhoid fever, or, as it is now fashionably called, typho-malarial fever. Some gave quinine from alpha to omega, but with no apparent benefit. It neither abated the violence, nor shortened the duration in the slightest degree in any case.

The doctors who gave it said it was recommended in certain books, and they considered it their Christian duty to prescribe it. I was called to one of these cases on the ninth day of the fever, the case was a girl of fourteen. She was most inveterately delirious.

The physician in attendance had give this beautiful maiden twenty grains of quinine per diem, for nine long, dreary days, and the stuff would neither act antipyretical or vaso-motorically!

This doctor said the girl was "pizened" with malaria, and he wanted to continue the quinine.

The spleen has now superseded the liver. We have all become leucocythemic instead of bilious.

I am living where malaria is supposed to reign supreme.

Where the crocodile croaks,
And the bullfrogs enchant;
Where the pond-lillies bloom,
And the lizards do haunt.
Where the goose and the duck
Forever do quake,
As they dip their broad bills
In the mud of the lake.

But inasmuch as this malarial phantom does not put in his appearance, unless the days are hot and the nights cool, I suppose I may be excused for not following the "traditions of the elders."

G. M. D.

KEYTESVILLE, MO.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from October 17 *to October* 23, 1880.

MATTHEWS, W. C., Capt. and Asst. Surgeon. His assignment to duty at Cantonment on Uncomphagre River, Col., revoked; and he is assigned to duty at Fort Wingate, N. Mex. S. O. 229, Department of the Missouri, October 16, 1880.

TORNEY, G. H., Capt. and Asst. Surgeon. When relieved by Asst. Surgeon Matthews, to proceed to Fort Lyon, Col., and report to the Post Commander for duty. S. O. 229, C. S., Department of Missouri.

GIBSON, R. J., First Lieut. and Asst. Surgeon. Relieved from temporary duty at Fort Leavenworth, and assigned to duty at the Cantonment on Uncomphagre River, Col. S. O. 229, C. S., Department of Missouri.

EXTREME RARITY OF ROUND ULCER OF THE STOMACH IN THE SOUTH OF RUSSIA.—Prof. Laschkewitch of Charkoff, in a letter to the editor of *Meditz. Vestnik*, calls the attention of the profession to the extremely rare occurrence of this disease in southern Russia. Since 1869, when he took the charge of the University therapeutic clinic, he had seen only one case of ulcer of the stomach, and that was in a Jewess. Examination of 383 autopsy reports failed to find a single mention of this disease, or of the scar indicating its previous existence.—*Meditz. Vestnik*, 1880, No. 29.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK. —At the annual meeting of this Society, held October 25, 1880, the following named members were elected as officers for the ensuing year: Dr. A. E. M. Purdy, President; Dr. F. A. Castle, Vice-President; Dr. W. M. Carpenter, Secretary; Dr. P. B. Porter, Assistant Secretary; Dr. O. B. Douglas, Treasurer; and Drs. D. Webster, F. R. Sturgis, R. A. Barry, P. F. Mundé, and D. Lewis, Censors. Thomas A. McParlin, M.D., Surgeon U.S.A., and George Edward Rindfleisch, M.D., Professor of Pathological Anatomy in the University of Würzburg, Bavaria, were elected honorary members.

THE "EPIZOÖTIC," though hardly so extensively prevalent in this city as at first, has been spreading through the country and has caused considerable injury to horse-flesh. Beginning at Boston, it reached New York about September 25th, where it spread rapidly. It soon travelled up the Hudson. It then appeared in Philadelphia and in the Delaware Valley. It extended up and down this latter district for many miles, and hundreds of horses were affected. About the same time it appeared in Cleveland, then in Chicago, and many western towns.

The disease is milder than when it appeared in 1872. The first symptoms (*Archives of Comparative Medicine*) are hanging of the head, shuffling gait, and a generally tired air, which are soon followed by a short, husky cough, sneezing, and a thin mucous discharge from the nostrils. The pulse is accelerated and the heart's action weak. The visible mucous membranes are injected, eyes watery, with occasionally slightly purulent secretions. As the disease advances all these symptoms increase; the temperature rises rapidly, in some cases to 107° F. The bowels become slightly affected, the appetite lost. There is marked tenderness over the larynx. On the whole, the symptoms are those of an acute coryza and laryngitis.

A curious sequel in many cases is purpura hæmorrhagica. This is a disease which gets its name from the fact that there are hæmorrhagic extravasations in the nasal and alimentary mucous membrane, and probably elsewhere. The legs and head become greatly swollen and œdematous. There is a well defined limitation to the œdema of the legs. The superficial vessels here seem to burst, and a bloody oozing stains the lower part of the extremities. There is an acute cystitis and nephritis in some cases. Sometimes, also, there is pericarditis, with great effusion.

The same influence which produces the "epizoötic" seems to have affected, to a large extent, human beings in this city at least. People who rarely have "colds," and who have not been at all exposed, are suddenly taken down with a very severe form of influenza. The attacks last longer and are much more severe than ordinary "colds."

It is useless to speculate on the causes of the present epidemic. It is, of course, attributed to some atmospheric influence, but further than that nothing certain is known. There is no specific treatment for the disease either in horses or men. Fortunately, few of the former and none of the latter die from its effects.

Listerism and Ovariotomy.—We copy part of a pungent editorial from the *Louisville Medical News*, and can heartily endorse the sentiments expressed by its editors: "A hot and acrid discussion is now in progress in England between Mr. Lawson Tait, the well-known ovariotomist, and Mr. Knowsley Thornton, a surgeon of large and growing fame in the same line of work. Mr. Tait claims to have had but two deaths in sixty ovariotomies performed without the carbolic acid spray. He speaks of patients 'killed by Listerism,' and declares that the recent reduction in the death-rate in this operation is largely, if not entirely, due to the introduction of Mr. Keith's intraperitoneal method. . . . . The editors of this journal are entirely in accord with Mr. Tait on this important question. The majority of the profession throughout the world follow Lister; but we believe the majority of the profession in this instance, as in many others which medical history records, is wrong. In republics the power is with the majority; but scarcely more in science than in religion and politics do truth and right necessarily dwell with the largest number. The majority in medicine once bled all fever patients with as little compunction as the maple-sugar makers tap their trees in the spring, and with equal confidence in the wisdom of their procedure. The majority in medicine used to regard salivation about as necessary to corporal salvation in serious sickness as the clergy tell us 'conviction and forgiveness of sin' are to the soul's eternal safety. If numbers prove the truth, then the crusades were wise, Mohammedism is right, and the opponents of Listerism are constructive homicides. Listerism is founded on the germ theory, and this is based on the microscope and the imagination. . . . . Medical dogmas as plausible as Listerism have flourished and perished in the past, and we have little doubt that before the close of the century Listerites will be as rare as white crows, if not, like the dodo, utterly extinct; and when discovered, they will be looked on as a curious specimen of the nineteenth century's medical credulity."

If we are correctly informed, Listerism in ovariotomy was abandoned for a time at the Woman's Hospital in this city. Excellent results were obtained while thus operating without the spray. Listerism was taken up again, however, largely on account of the remarkable success that Wells and Keith were having while operating with it. In the large general hospitals of the city the method is not very extensively used, and has of late rather lost ground.

Red Perspiration in Axillæ.—Dr. H., of Savannah, Ga., writes: "I noticed, in a recent issue of the Record, a short article on 'Red Perspiration of the Axillæ,' in which the words, 'The perspiration from the axillæ stained the shirt red, but occasioned no other inconvenience.' As I am subject to this red perspiration of the axillæ, and suffer no other inconvenience whatever, I can corroborate the above statement.

"The description of the state of the hairs in the article referred to corresponds exactly to the condition of mine. But a strange feature in my case is, that although I always perspire a great deal every summer, saturating my undershirt at least once daily since the first day of June, as well as I can remember, it is *only occasionally* that my shirt is stained red at the axilla; and I think that this is more likely to occur if I take an unusual amount of exercise, such as a long walk out of town, or rowing. In the Record of May 22d, p. 580, is another article on the same subject, by Dr. W. A. Dayton, in which he says: 'In each instance the patients were afflicted with pediculi pubis, and the axillæ were inhabited.'

"Now, on this point I think the doctor is entirely mistaken, and as far as my own case is concerned I *know* he is mistaken, as I never yet had to support a family of pediculi pubis, and I have been subject to the red perspiration of the axillæ for several years.

"Another fact which induces me to believe that Dr. Dayton is mistaken in regard to the cause of this affection is that in my case I have never known this red perspiration to occur except in summer, while I am inclined to think that in this climate (perhaps also in others) the pediculi pubis will affect persons in winter as well as in summer. Although I have, while hunting, been perfectly covered with perspiration in the middle of winter, yet I have never noticed a red stain or the peculiar condition of the hairs at that season.

"As to the treatment, I have not yet given it a thought, but I find that a liberal and daily application of soap for weeks continued has not removed that peculiar condition of the hairs; and from the fact that I have been in the habit of using soap and water liberally and daily, winter as well as summer, I *know* that their use has not prevented the affection in my case, but it has prevented the hairs in the arm-pits from being 'invariably matted together with the honey (?) secretion.'

"If this affection were produced by 'a sticky substance (honey?) covering the hairs,' this substance would impart its *stickiness* to the perspiration, and through it to the fabric of the shirt, but I have not found this to be the case.

"Although I have not made a microscopical examination of the hairs thus affected, I am inclined to think, with Dr. Key, that the affection is due to a peculiar fungous vegetation."

The Human Tail.—Virchow (says the *Chicago Medical Review*) makes the receipt of a communication about an alleged case of tail in man, from one of his Greek correspondents, the occasion for a full review of this subject of caudate human beings. He considers the condition of so-called sacral trichosis, in which a large tuft of hair is found at the sacral region, as related hereto. Instances of this latter kind indicate probably a genuine ancestral trait, for a tuft of hair on the sacrum is all that represents the tail in anthropoid apes. The immediate ancestors of the human race were as tailless as men themselves, and as their nearest living relatives, the orang, gorilla, chimpanzee, and gibbon. The presence of a true tail in a human being can therefore be regarded only in two lights—either as a hap-hazard monstrosity, or an atavism in the sense of the preservation of an early embryonic feature. Among well authenticated examples of human tails, Virchow describes that of an infant born in Oldenburg. It had a tail which it could move and which was coiled up like that of a pig. He suspects that among certain little studied races, Tartars, Greeks, and possibly some African tribes, this feature may be of more common occurrence than in our own. He finds in such tails as he has examined no true vertebral elements; the only feature which exhibits its homology is a central cord, representing, perhaps, the chorda dorsalis.

Watermelon Seeds impacted in the Rectum.—Dr. E. J. Bergen, of Wamego, Kansas, writes: Seeing a few weeks ago an account of an accumulation of watermelon seeds in the rectum, I send you the following: About the first of September last, I was called in the night to see a girl, aged ten years, the daughter of Mr. R., who lives seven miles south of this town. After having examined the child, I was not satisfied as to what was the matter, but as her bowels had not moved for a day or two, I left a dose of calomel and jalap, with instruction to give it to the girl, and came away. The next day I was sent for again, and as she was then complaining of considerable tenesmus, I made an examination of the rectum, and saw a watermelon seed projecting from the anus. Taking the smallest blade of a Sims' speculum, which I happened to have with me, I inserted it in the bowel, and obtained, after a good deal of difficulty, over one-half pint of seeds, with complete relief to the child.

Antiseptic Treatment of Typhoid Fever.—Dr. J. H. Putnam, of Rutland, Vermont, writes: In the issue of the Record, dated Oct. 2d, I noticed an article in relation to a new method of treatment—the antiseptic—of typhoid fever, by Dr. C. G. Rothe. I have been in practice thirteen years. The first eight years I treated my cases of typhoid fever according to the prescribed methods, embracing quinine, acids, turpentine, opium, calomel, etc., reading Flint and Aitken principally as text-books. I was located in a section of country where I saw a large number of patients for a country practitioner. It was my lot to lose a number of cases. Five years ago I adopted a new method of treatment—the antiseptic—and I have not had cause to regret it, as all my cases have recovered. My treatment now is hyposulphite of soda, charcoal and carbolic acid. Milk and beef-tea in abundance, and stimulants if required. I find this difference in symptoms: tongue and mouth remain moist; seldom any delirium, and when present only slight, bowels slightly tympanitic, and in most cases entirely absent. The majority of cases beginning to convalesce the fifteenth day, occasionally running to the twenty-first day; but I have not had to contend with those long lingering cases of four and five weeks' duration. I rely mostly upon the hyposulphite. When it causes nausea I use the carbolic acid. If diarrhœa is active I use the charcoal. I keep the vapor of bromine in the sick-room all the time. If patient is restless and an anodyne is required, I use the bromides in milk, or valerianate-ammonia, or some mild anodyne. Not opium, because it locks up the bowels too much. I prefer my patient would have from four to eight discharges daily, because it keeps the bowels empty, not allowing the products of the ulceration to remain long in the alimentary canal. I insist upon the use of large quantities of milk, and at stated hours; the length of time between taking nourishment depending upon the ability of the stomach to retain it. I believe the antiseptic remedies do for the contents of the intestines just what we seek to do when we use a disinfectant in the vessel which receives the evacuation. I have no doubt the remedies have some local action upon the ulcers, but it is apparent that they cannot be administered in a form strong enough to make a decided impression without injury to the stomach and passage thereto. The above method of treatment is not original with me, but the result of suggestions made to me by Dr. M. Goldsmith, Rutland, Vt.

Mathematical Calculation in a Dwarf.—Dr. Samuel W. Francis, of Newport, R. I., writes: In a recent number of your journal you mention an interesting case of a dwarf in Europe, whose powers of calculation were remarkable. I remember distinctly witnessing a similar phenomenon in New York, some four years since. While visiting Dr. Sayre, a dwarf, about eleven years old, with a curved spine, came in the office to be treated by Dr. Sayre's method of employing hanging as one of the fine arts. While there the dwarf asked Dr. Sayre the day and year he was born, and before several gentlemen, and without any aid but his brain, told him in *three minutes and a half* exactly how many seconds he had lived. It is well to record such cases.

Treatment of Fetid Perspiration of the Feet.—Dr. F. E. Maine, of Philadelphia, writes: In the fall of 1876 a young man came to me suffering from a most disagreeable bromidrosis. Remembering the common treatment by astringents and cleanliness, I at once recommended him to wash the feet each night and morning with a strong castile soap-suds, and gave him for an application:

℞. Acidi tannici........................ ℥ ij.
Aquæ........................... ℥ iv.

M. S.—Apply after the bathing and at once put on socks.

This was faithfully used for over a week, but no improvement could be discovered and a change was necessary, and I gave him a large lump of alum and told him to put it in enough *hot* water to wet his socks in (in order to get as strong a solution as was possible) and let what would dissolve, and then wet the socks in it and put them on hot and wet, and he tried that for two weeks, at the end of which time a very slight improvement was visible. Not satisfied, I tried clear alcohol, but, like the latter, it was slow. The strictest cleanliness was enjoined, but my patient was discouraged and said I must do something as soon as possible that would do some good, and not knowing what else to try I finally settled on chloral hydrate and prepared a tincture of the drug in the following manner:

℞. Chloral hydrat.................. gr. xx.
Spts. vini...................... ʒ iij.

M. S.—Bathe the feet thoroughly in castile soap-suds. Apply the solution with a sponge, and put on socks while feet are wet.

The preparation was used that strength for four days when the young man returned reporting a greater improvement than he had seen during the whole period of treatment before used. And upon examination I found the stench was very much diminished and they had not sweat as freely. I gave him a solution of just double the strength of the other and advised him to use it the same as the other. On the fourth day he returned again and said "a new skin was coming all over the bottoms of his feet and the old skin was most cleaned off."

He continued to use the preparation for two weeks more and was entirely cured. I saw the patient during the month of September, 1880, and he says he has never had any recurrence of the trouble.

The second case came to me by recommendation of No. 1, and was much the same in nature, and the treatment was the same and was cured in less than three weeks.

The third case which I have full notes of and give you the history of was the sixth case that came to my notice, and was the worst case of the disease I ever saw. I will give you the history just as it is given in my note-book.

Male patient came to office first time, morning, August 2, 1879. Disease—bromidrosis, very severe. Soles of both feet white, puffy, and so tender he cannot walk without producing the most severe pain. Stench unbearable, and the feet sweat so profusely that he can wring water from his socks after having them on but half an hour.

Prescribed :

℞. Chloral hydrat........ .... ʒ vi.
Spts. vini .... ℥ v.
Aquæ......................... ℥ iij.

M. S.—Bathe the feet thoroughly in hot castile soap-suds, wipe dry, and apply, with a sponge, the solution and put on the stockings while feet are yet wet.

To be applied thrice daily. Patient told to come again in one week.

August 11th.—Patient returned. The edges of the white, puffy skin are loosening and the stench is not so bad. Continue the treatment and return in one week.

August 18, 1879.—Patient returned. Brought the soles of both feet done up in a paper. Reported that "they came off the 16th, when he took off his socks." Healthy skin all over the bottoms of the feet and no stench of account. The sweating nearly stopped. He thought the solution most too strong, as it smarted him. Diluted with one-third water. Continue the treatment and report soon.

August 30th.—Patient walked to my office a distance of one-half mile. Said, "Could not have done that six weeks ago to save his life." Gave him some more of the preparation as weakened. Told to use until skin became tough. I have seen the lad recently, and he has never had any recurrence to present date, October, 1880.

Nerve-Stretching for the Cure of Lumbago and Sciatica without any Cutting Operation.—Dr. James M'Craith, of Smyrna, writes to the *British Medical Journal* upon the above topic : "I have had," he says, "very lately an attack of lumbago, for the first time in my life. A patient of mine, whom I could not go to see came to my house and volunteered to cure me, assuring me he had cured, almost instantaneously, several people suffering in the same manner as I then was, by kneading and pressing very hard the parts affected. He placed me on my face and hands on the sofa, and kneaded the painful parts very forcibly for some time, and then he said : 'I don't hear the cric-cric which I always hear when I succeed at once, so I fear I shall not succeed with you.' This is evidently the sensation of 'adhesions giving away,' as described by Dr. Bramwell, when the cure is satisfactory. I have known of cases of torticollis getting suddenly well, also of pain in the shoulder, on some violent movement being made. These are evidently cases of 'nerve-stretching,' and I think we have got at the true scientific explanation of the success of the popular proceeding in those cases ; and with the distinct object of 'stretching the nerve' and 'breaking up the existing adhesions,' we may adopt with advantage, and much greater chance of success, this popular method. In severe cases, chloroform may have to be used, as the kneading is painful."

A Change from Hypermetropia to Myopia, in the eyes of four persons, is recorded by Dr. S. D. Risley (*Am. Jour. of Medical Sciences*). The cases were under his care all the time. The change took place in two cases within two years. The ages of the patients varies from nine to twenty-eight.

Milk Diet and Rectal Accumulation.—Dr. D. W. Niles, of Worcester, Mass., calls attention to a peculiar tenacious pultaceous fæcal accumulation in the rectum as a result of continuous milk diet. In a case to which particular reference is made, the mass could only be dislodged from the rectum by mechanical means. Milk diet tried upon a perfectly healthy individual for forty-eight hours, caused the same kind of accumulation within the rectum.

A Novel Treatment of Hydrophobia is related by a correspondent of *The Lancet* as being practised in certain rural districts of England. A boy was bitten by a dog and severely lacerated on the face. There were three deep cuts, one requiring a stitch. In order to preserve the boy from any possibility of contagion, the friends adopted the following procedure : They wiped all the saliva they could get out of the dog's mouth, rubbed this well into the cuts, and then shot the dog. It is a common belief among the district where this occurred, that such a procedure will infallibly prevent the bitten person from going mad.

Double Gestation.—A case of double gestation is reported by Dr. P. J. Murphy in the *Obstetric Gazette.* The patient, a young married woman, had one child four years before. The last pregnancy was attended with no unusual symptoms except some œdema of the legs. Labor came on regularly and a child was born, weighing about four pounds. It was very weak, and evidently not more than eight months old. About twenty minutes after its birth a four months fœtus was delivered. There was a separate placenta to each fœtus. The patient made a good recovery. Twins had "run in the family."

Dr. Austin Flint, Jr., has declined an invitation to accept the Chair of Physiology in the Jefferson Medical College of Philadelphia. The Bellevue Hospital Medical College is to be congratulated on this decision. But we wonder what Philadelphia had to offer which New York has not—outside of Dr. Buchanan.

The Night Medical Service.—Sanitary Inspector Ewing, executive officer of the Night Medical Service, presented to the Board of Health a report of the operations of the service from the 5th to the 30th ult., during which period there were 27 visits paid by 15 different physicians. In one case the patient died before the arrival of the physician. Of the 27 patients, 3 paid the fee for the physicians visits. Dr. Ewing reported that he had investigated the majority of these calls, and found them, without exception, cases of sudden illness or emergencies occurring in the night-time among the poor, and there appears to be no attempt on the part of any one to take undue advantage of the charity.

Original Communications.

SOME OF THE UNSETTLED QUESTIONS CONCERNING NASAL CATARRH.

By FRANK H. BOSWORTH, M.D.,
CLINICAL LECTURER ON DISEASES OF THE THROAT IN THE BELLEVUE HOSPITAL MEDICAL COLLEGE, NEW YORK.

[Read before the New York Academy of Medicine, October 21, 1880.]

Mr. President and Gentlemen of the Academy of Medicine:

I HAVE designedly announced my subject as "Some of the Unsettled Questions Concerning Nasal Catarrh," with the object of bringing before you certain conclusions which an exceptional experience in dealing with this troublesome disease has led me to adopt; and also that I might elicit a discussion which it is my hope may serve somewhat to throw more light upon the subject, and place on a better footing some of these vexatious questions.

The main points which I desire to discuss are: first, What is nasal catarrh? second, What are its tendencies? third, How can we treat it? and fourth, Can we cure it?

The first question that we have to decide is, What is nasal catarrh?

If we glance over the literature of the subject, we meet with a host of names which in their multitude certainly add nothing to the clearness of our nomenclature of diseases. Among these I might mention naso-pharyngeal catarrh, post-nasal catarrh, chronic pharyngitis, retro-pharyngeal catarrh, glandular hypertrophy of the vault of the pharynx, adenoma of the vault of the pharynx, clergyman's sore throat, follicular pharyngitis, hypertrophic nasal catarrh, nasal stenosis, infiltration of the septum of the nares, etc. I may have omitted some, but these are all that occur to me. There is but one disease embraced under all these names, and it is nasal catarrh, and I prefer to retain the old name, not only out of deference to a very ancient usage, but also from the fact that it defines the disease more simply and quite as completely as any other.

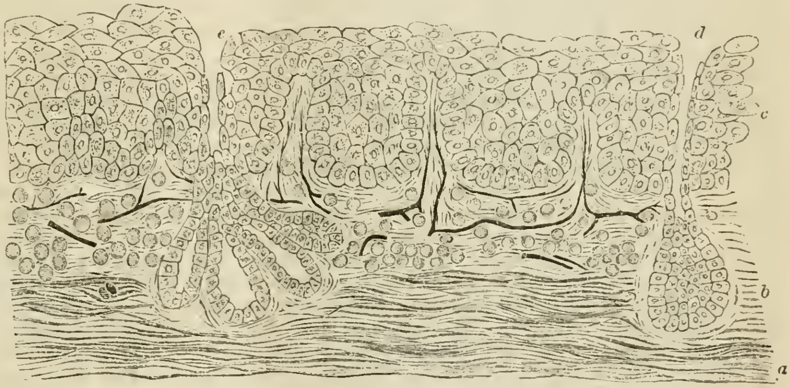

Fig. 1.—Section of a mucous membrane: *a*, submucous layer of connective tissue: *b*, mucous membrane proper, containing blood-vessels, nerves, closed follicles, connective and elastic tissue fibres, and marked by villi; *c*, epithelial layer; *d*, simple follicle; *e*, racemose gland.

The question arises, first, what region is involved in the disease. If we glance at a sectional diagram of the head, it will be seen that the border of the soft palate marks the boundary line between two avenues of the upper air-passages which are totally distinct and separate, both as regards their functions and the influence of their surroundings. In that portion below the border of the palate we have a region which is being constantly impinged upon and swept by the passage of food and drink, the result of which is necessarily that an accumulation of mucus is prevented, the surface of the membrane is kept comparatively clean, and the mouths of the follicles are kept open. On the other hand, we find that the region which is above the border of the soft palate is subjected to entirely different influences. It is traversed by the current of air in respiration, and virtually nothing more. It of course is endowed with certain functions in phonation, and is also the organ of the sense of smell; but in this respect, for the present, it does not concern us. It is lined with a mucous membrane richly endowed with glands, and there is constantly going on a secretion of mucus, together with an evolution of epithelium in the process of growth. Nature has provided but one method by which this accumulation is gotten rid of; the epithelial cells are endowed with ciliæ, by which the mucus and worn-out epithelium are carried toward the outlets of the passage.

The essential difference between the two regions, therefore, lies in the fact that the lower pharynx is constantly traversed and impinged upon by solids and fluids, while the upper passage is only traversed by the current of air in respiration. Hence the lower region is kept comparatively clear of accumulations, while in the upper region the mucus secreted, and the worn-out epithelium tend to accumulate in the sinuous passages, and remain in contact with its lining membrane. Especially is this true if, as the result of chronic inflammation, the ciliæ with which the epithelial coat of the membrane is endowed be destroyed. As the result, therefore, of this marked difference of function and environment, it seems to me a fair conclusion that the true boundary line between these two regions should be drawn at the border of the palate.

Now, anatomy teaches that the nasal cavities extend from the nostrils, anteriorly to the two oval openings of the posterior nares, where they open into the pharynx; and that the pharynx is that cavity which extends from the basilar process of the occipital bone to the entrance into the larynx and œsophagus. As the result of this anatomical division, and based upon it, we have a classification of diseased conditions which is utterly confusing. The point, then, which I would make first, is, that whatever the anatomical division may be, the true nasal cavity is the one I have described, and extends from the nostril to the border of the soft palate, and includes what we usually call the vault of the pharynx. This division is justified by the physiological division of the parts, as I have said; furthermore, and more prominently still, it is the division which, from a pathological point of view, must be made; for it is this whole region which is affected in the disease we are discussing. Nasal catarrh, therefore, is a chronic inflammation of the mucous membrane lining that portion of the upper air-passages, which extends from the nostrils anteriorly, to the posterior border of the soft palate.

The next point which presents is, What is the character of the morbid process which constitutes the disease? In Fig. 1 there is shown a section of a mucous membrane. There will be noticed the three layers of which it is composed: a basement layer of connective tissue, a middle layer, composed of fibrous and elastic tissue, muscular fibres, blood-vessels, rounded, closed follicles, and simple and racemose follicles, whose ducts pass through the superficial epithelial layer, and open on the surface of the membrane. This layer is marked by minute projections, or villi. The superficial layer is composed of epithelial cells, displayed in a number of layers one upon the other. Now, when a mucous membrane is acutely inflamed, what takes place is briefly as follows: the blood-vessels become distended with blood, enlarged and tortuous; the white corpuscles accumulate at the sides of the vessels, and finally pass through the vascular wall, carrying with them a certain amount of liquor sanguinis. These escaped white blood-corpuscles constitute the so-called leucocytes or amœboid corpuscles. In connection with this, and probably as the result of it, the normal processes of the membranes are stimulated to great nutritive activity. The rounded cells in the mucous membrane proper are proliferated, new epithelial cells are generated, the glands pour out their mucus, and all the normal processes of growth and secretion become enormously exaggerated. This constitutes the acute inflammatory process. Now, in a chronic inflammation, virtually the only difference we recognize is that the hyperæmia of the membrane subsides, but all the exaggerated nutritive processes go on. There is excessive cell-proliferation, there is abnormal secretion, and there is poured out from the surface of the membrane an excessive secretion, which is more or less charged with young, unripe cells, constituting a mucus or muco-purulent discharge, according as the cell-proliferation is active and the secretions become charged with the young cells and worn-out epithelium. Applying this, now, to the membrane lining the nose. As this chronic morbid process goes on we find that it undergoes a form of genuine hyperplasia. Its meshes become infiltrated with these young cells, new connective tissue and elastic tissue fibres are developed, while, at the same time, the superficial or epithelial layer becomes piled up and thickened by the development from beneath of the new epithelial cells, the result of the morbid activity; and we have the whole membrane, in process of time, becoming markedly thickened or hypertrophied. while, at the same time, the secreting organs are pouring out their excessive mucus or muco-purulent discharge.

Now, if we glance at the plate again we will understand how this abnormal deposit of neoplastic tissue in the membrane may, to a certain extent as the result of mere adventitious circumstances, result in one or the other of two very distinct conditions. If the secretory organs of the membrane undergo the same hypertrophy as the other portion of the membrane, we have a genuine hypertrophy of the mucous membrane, characterized prominently by thickening, together with an excessive secretion. If, on the other hand, we have the adventitious results of the morbid process so distributed in the membrane as to encroach upon its glandular structure we may have an entirely different condition resulting. The glands gradually succumb to the pressure upon them, their activity is destroyed, and they undergo atrophy. The membrane, therefore, becomes deprived of its supply of normal mucus, and we have a dry catarrh.

We thus have the explanation of the first division we are compelled to make in the classification of nasal catarrh. In the first variety we have a hypertrophy of the membrane lining the nasal cavity, resulting in a nasal catarrh whose prominent symptoms are excess of secretion with narrowing of the nasal passages. The natural tendency of all nasal secretion is toward the fauces; this is increased by the disposition to constantly draw or snuff back through the nose. The mucus, therefore, accumulates in the upper pharynx, or is drawn down into the fauces and lodges between the palate and wall of the pharynx, giving rise to the feeling of a mass or plug in that region, which is attempted to be dislodged by that disagreeable nasal screatus with which we are familiar. That the main source of the excessive mucus discharge in nasal catarrh is the nasal cavity proper I have repeatedly verified, by arresting it by means of remedies applied to the turbinated bones. If the secretion is excessive there is liable to be the constant dropping in the throat of which patients so often complain.

As a further result of this thickening of the membrane of the nose we have the normal breathing space narrowed—nasal respiration is interfered with. This becomes a source of extreme discomfort to the sufferer, and also compels him to breathe through the mouth. The long-continued action of respiration carried on habitually through the mouth is a prolific source of catarrhal inflammation of the lower pharynx and larynx. Of this fact I think there can be little doubt. This is very well illustrated in the case of a mild acute inflammation in the larynx. Those of us who have suffered from a subacute laryngitis or pharyngitis will recall the effect of a long inspiration through the mouth, giving rise to marked irritation of the parts with oftentimes an attack of coughing. The explanation of this, of course, is familiar to all. The current of inspired air passing over the blood-warm, moist, and sinuous passages of the nose becomes warmed, moistened, and cleansed in its passage. This does not take place in its passage through the mouth, hence it becomes to an extent irritating to the lining membrane of the larynx and pharynx. This deleterious action of breathing through the mouth, which is compelled by nasal stenosis, explains the frequency with which the throat symptoms in nasal catarrh are complained of by patients, while the nasal disease is, to an extent, overlooked.

This hypertrophic form of nasal catarrh is the one with which we have to deal in the very large majority of cases; and is the one concerning which what I have to say to night relates in the main.

A few words, however, will suffice to explain how the other form of the disease may arise from pathological changes, which are mainly identical in the two forms of the disease.

The essential pathological change in the membrane is a deposit in its meshes of newly developed cells and fibres.

Now, in that form of the disease in which the newly deposited material encroaches upon the glandular structures, we find that their activity is to an extent destroyed, and the membrane is robbed of its normal supply of mucus.

There is, therefore, poured out on its surface a thick mucus which is deficient in its watery constituents, and hence it dries rapidly, forming a thin crust or mass, which adheres closely to the parts beneath. There is thus formed a pellicle upon the membrane covering it and extending over the convexity of the turbinated bones and into the sinuous passages. This pellicle dries under the influence of the current of air passing over it, but it protects the parts beneath, forming, as it does, a complete air-tight shield. Secretion goes on beneath it nevertheless, and this secretion is not deprived of its moisture by the current of air, for the air does not reach it. The secretions are imprisoned, undergo degeneration, and become fetid and offensive. There is now a purulent discharge established—a discharge which in many cases is almost pure fluid pus. This, I am disposed to think, in many cases serves to infect the membrane as it were, and excites a still further purulent discharge, whose source is largely in the epithelial layer. As this purulent discharge is poured out, the dried pellicle is lifted from the membrane, but the loss of moisture still going on, we have built up those thick, offensive, fetid masses, or crusts, which are dislodged with so much difficulty, and which render this form of the disease so distressing in the intolerable stench which often attends it.

We thus have accounted for the two forms of nasal catarrh by virtually the same pathological change in the onset of the process. These two forms virtually comprise the whole subject. Excluding, of course, syphilis with its attendant ulceration and necrosis; and disease of the accessory cavities, as of the antrum of Highmore, and the frontal sinuses, which constitutes true ozæna, both of which are diseases entirely different from true nasal catarrh.

In this connection it might be mentioned that ulceration in the nasal cavity is not a symptom of nasal catarrh. I have never seen it except in syphilis, scrofula, or some of the blood poisons. With the exception above noted, then, all forms of nasal catarrh may be embraced under the two heads above described. Hypertrophic catarrh, with excess of secretion and narrowing of the passages, and atrophic catarrh, with its resultant fetid discharges. This latter form of the disease I do not propose to further discuss in the necessarily limited province of this paper. The hypertrophic form of the disease, as before stated, is the one which presents for treatment in the large majority of cases, and is the one which will be the subject of what remains to be said.

Another question which may be briefly noticed in this connection is the cause of nasal catarrh; and first, Is there a catarrhal diathesis? We have already the tuberculous, strumous, rachitic, gouty, rheumatic, dartrous, neurotic, and possibly other diatheses. Shall we add, also, a catarrhal diathesis? It seems to me that those already mentioned have done mischief enough with their confusing and discouraging tendencies. A catarrhal diathesis does not exist. The disease is purely a local one. It occurs at all ages, in both sexes, and in all conditions of birth, color, and social position. It occurs in persons otherwise in the enjoyment of perfect health, and does not seem to be aggravated by an impairment of the general health from intercurrent causes. It occurs in one member of a family to the exclusion of others, and is not hereditary. It may involve one or both nasal cavities, but is often more marked on one side than the other. It occurs in men more frequently than in women, simply because men are more exposed than women. The true explanation of the very great prevalence of the disease may be stated as follows: The upper air-passages, owing to their exposed situation, are extremely liable to take on a mild morbid condition. This is due entirely to the fact that they are exposed to the first ingress of the inspired air, with its varying temperature, humidity, and purity. From its dampness or from its containing particles of dust, irritating vapors, and other deleterious matter, the air we breathe serves to irritate the upper passages, and causes a mild chronic inflammation. As the result of this, the liability to take cold ensues. These attacks serve to aggravate the chronic condition. As months or even years go on there results a chronic catarrh.

It may result from measles or scarlatina, simply because those diseases are attended with an acute coryza, which, from its protracted course, undergoes incomplete resolution, and lapses into the chronic process.

It should be further added that it is essentially a disease of those climates which are characterized by frequent and rapid changes in temperature and great humidity, while in the drier and more equable climate of the tropics it does not prevail to the same extent.

The next question for consideration is, What are the tendencies of nasal catarrh? As already intimated, one of the direct results of the disease in the nasal cavity is the development of a catarrhal inflammation in the pharynx and larynx. This was explained as being due to the deleterious influence of respiration carried on habitually through the mouth, this mode of breathing having become a necessity as the result of the nasal obstruction. This tendency is still further aggravated by the secretions from the nose and upper pharynx passing down the pharyngeal wall, and finally making their way into the laryngeal cavity, where they necessarily act to cause a morbid condition.

Whether there is direct extension of the inflammatory process from the nares to the lower pharynx and larynx I think is very doubtful.

We have then established a chronic inflammation of these organs. The existence of the chronic morbid condition entails an especial liability to take cold from slight provocation,—the so-called liability to take cold I believe in every case to mean that there already exists a mild chronic inflammation, which takes on a renewed activity from a slight exciting cause. As the result of these repeated attacks of acute inflammation, the chronic morbid process becomes aggravated. Each fresh attack undergoes less perfect resolution. Furthermore, as these attacks recur, there is a disposition to their extension farther toward the lungs. Eventually, there sets in a bronchitis, with persistent and troublesome cough. The repeated colds recur with greater frequency, and resolution becomes more protracted and less perfect. The sequence of events, then, is a nasal catarrh, a pharyngitis, a laryngitis, a tracheitis, and finally a bronchitis. That this is a frequent sequence of events, when we consider the very great prevalence of nasal catarrh, I do not of course assert, but that it is a not uncommon occurrence I do not think can be controverted. A nasal catarrh, then, I think we may safely regard as a menace, if nothing more, to the air-passages farther down.

We are frequently asked the question, as physicians, by those suffering from a nasal catarrh, will the catarrh extend to the lungs? I do not think we are justified in answering No to the question. I believe that it is the tendency of the disease in many cases, and that we should say so. That a given case will necessarily develop into pulmonary disease, of course, cannot be said. That it is a not improbable danger is certainly true.

Aside from any danger that menaces the lungs in the existence of a nasal catarrh, that a chronic laryngeal catarrh arises in a large proportion of cases as the result of the nasal disease cannot be questioned, and this becomes a matter of no little gravity in those who may be dependent on the healthful condition of the vocal apparatus.

We come now to the consideration of by far the most important question which presents itself in connection with the disease, viz., the treatment. The disease, as we have found, consists essentially in a true hypertrophy of the mucous membrane. In connection with the hypertrophy there is abnormal secretion. The two symptoms are virtually one as regards measures of treatment. The removal of the thickened membrane removes the source of the discharge. Hence there is no good reason for discussing separately, measures for the relief of one or the other of these symptoms.

When the nasal douche of Weber or Thudichum was first suggested it was thought that in this rather ingenious device we were finally to be put in possession of a mode of treatment which would enable us to cope successfully with nasal catarrh. I need not say that the douche has proved a most signal failure in accomplishing more than a moderate degree of relief to the more prominent features of the disease.

The stream which enters one nostril passes around the septum and makes its escape through the other nostril. It traverses the passages in a slow and sluggish manner, bathing the lower passage and turbinated bone. That the fluid mounts higher than the middle meatus is questionable. It fails then to thoroughly reach all the parts; it fails to completely cleanse the membrane of its accumulation of mucus; and it exercises but a moderate amount of influence on the diseased tissue. It does nothing more then than to relieve in a moderate degree the subjective symptoms of the disease.

Nearly thirty years ago the idea of making local application to the air-passages of fluids in a state of fine atomization was first carried into practice. The methods by which this was accomplished were at first somewhat rude, but the introduction subsequently of the principle of Lewin, and later, that of Bergson, have placed in our hands instruments for the atomization of fluids and for applying them to such parts as we may desire, which are everything that could be wished. The nasal douche failed, and the principle of atomization was received with an enthusiasm which led to the expectation of great results from its use. The atomizer enables us to make application of medicated fluids to the nasal cavities in such a manner that there can be no doubt that every portion of the membrane is reached and acted upon. In this it is undoubtedly a more valuable device than the douche.

We have used the sprays now for over twenty years, and we should be able to say with considerable definiteness how far they have justified the early expectations.

By their use the morbid activity of the inflamed mucous membrane is to an extent controlled, the secretion is lessened, and, if the case be a mild one, the disease may be arrested. But in the more aggravated cases, attended with a considerable degree of thickening of the membrane, the best that can be expected from the use of sprays is that the disease may be to an extent deprived of its more troublesome symptoms. A permanent cure is, as a rule, not accomplished, the disease generally returning, sooner or later, in as aggravated a form as before.

The method of treating nasal catarrh, then, by the sprays we must also regard as, to an extent, a failure. In the use of the douche and the spray, then, we have exhausted our most ingenious methods of managing this disease by means of topical medication.

I do not propose to enter upon the discussion of the use of powders. What is said as to the efficacy of sprays applies equally well to the use of powders. On the one hand we have a topical agent diluted in water diffused through the nasal cavity by means of an atomizer. On the other hand it may be equally diffused by the insufflator, but reduced by a neutral powder.

The devices alluded to failing us, then comes the final alternative of resorting to some destructive agent, by means of which the hypertrophied membrane may be ablated.

For some years there has been a growing conviction on the part of those who come in contact largely with throat diseases, that topical agents fail to accomplish all that should be accomplished in these cases, and, furthermore, that in the use of destructive agents lies the only plan of treatment which will enable us to cope, with any hope of success, with a large proportion of cases of nasal catarrh. Whether this conclusion is the true one or not I do not propose to discuss. It is a conviction which I have arrived at after a considerable experience, both in private and dispensary practice, of the frequent inefficacy of the simpler plan of treatment, and one to which an every-day experience is adding strength.

I shall therefore simply add some brief considerations in regard to the various means by which these destructive measures may be carried out.

I show here (Fig. 2) a pair of forceps with long, tapering blades, toothed in their whole length, which have been designed for the purpose of seizing the hypertrophied tissue, and partially cutting and partially tearing and wrenching it away. The operation is a bloody one, and terribly painful; it furthermore bruises and injures the healthy tissues, often to an unjustifiable extent. I have never felt myself warranted in resorting to the use of this instrument.

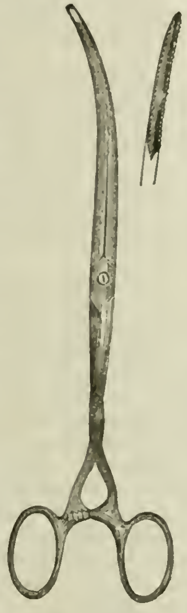

FIG. 2.—Robinson's forceps for the evulsion of the mucous membrane over the turbinated bone.

Chemical agents for the accomplishment of this purpose are often resorted to. Of these I shall refer briefly to nitrate of silver, nitric acid, chromic acid, and acetic acid.

There are few agents of greater value than nitrate of silver, if properly used, and few that have been more abused by improper use. It is an escharotic of undoubted activity, but it also possesses another property which is too often overlooked. It is a very powerful stimulant. Hence, in its use, while it may destroy the superficial layer of the membrane in the disease we are considering, it also stimulates the morbid processes in the deeper layer to such renewed activity that there results a morbid action there, which fully, if not more than counterbalances all that has been accomplished by the superficial cauterization. This remedy, then, I should decidedly condemn for the purpose of destroying the hypertrophic tissue in nasal catarrh. I recall with some satisfaction that in the past three years I have rarely made use of nitrate of silver of a strength greater than twenty grains to the ounce as a topical agent, with the sole exception of the use of the solid stick, in destroying mucous patches.

In nitric acid we have a powerful escharotic not open to the objection made to the nitrate of silver. It is an efficient destructive agent, possessing no marked stimulating qualities, but there lies the difficulty of controlling and limiting its action. This objection has been largely overcome by the ingenious little device of Dr. A. H. Smith, of this city (Fig. 3). This consists of a hard-rubber tube containing an oval fenestrum. This is passed into the nasal cavity until the part which it is desired to cauterize pouches into the fenestrum. A slender probe, wrapped with a pledget of cotton, is dipped in the acid and passed into the tube to the opening. The action of the acid is thus confined to that portion alone of the mucous membrane which lies against the opening in the canula. We possess no better means of using so powerful an escharotic as nitric acid. The only objection that would remain against the use of nitric acid is that it erodes deeply, and that a troublesome ulcerative process may be established, which may become a source of annoyance by delayed healing.

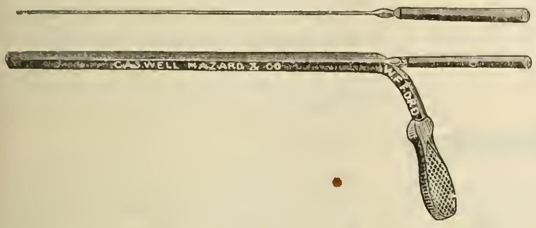

FIG. 3.—Smith's canula for applying nitric acid to the nasal mucous membrane.

Chromic acid presents in its acicular crystals an extremely convenient form of application, and is also an efficient escharotic. I am disposed to think it possesses many of the advantages of nitric acid and none of its disadvantages. I have, however, made such limited use of this remedy that I cannot speak of its virtues. Of all the chemical agents for cauterization my preference is very decided in favor of the glacial acetic acid. I have for nearly a year made frequent and increasing use of this agent, and I am rarely disappointed of excellent results. It is mild and yet efficient in its action. It possesses no marked stimulating qualities, and it not only serves to destroy the superficial layer of the hypertrophied membrane, but by its absorption it seems to exercise a marked controlling influence on the morbid activity of the chronic inflammatory action in the deeper layer of the membrane.

When first applied it occasionally seems to cause some irritation, as the result of which the membrane swells up, and the patient suffers for a few hours or a day with many of the symptoms of an ordinary cold in the head. This, however, subsides very soon, and there is soon voided shreddy masses much resembling a croupous membrane, after which there is a marked amelioration of all the symptoms.

I show here (Fig. 4) a small flattened and bent probe, by the use of which the acid is very efficiently applied. This probe is wrapped with a pledget of cotton, and then the acid is taken up on another probe and dropped on the side of the wrapped probe until that side is fully charged. It will be found then that the acid is confined to one side of the probe, and that in passing it into the nares the septum is not touched by the escharotic. Of course, the acid is placed on that side of the probe which will come in contact with the turbinated bone of the side it is desired to medicate. After the probe is charged it is swept rapidly through the nasal passage in such a manner that the face of the turbinated bone is touched in its whole length. This may be repeated for the middle turbinated bone if that is diseased. The application is, of course, extremely painful, but this may be instantly relieved by throwing in immediately, by means of the atomizer, a small amount of the following:

℞. Acidi carbolici........ gr. j.
Sodæ biborat.,
Sodæ bicarb........āā gr. ij.
Glycerin.............. ʒ j.
Aquæ..............ad ℥ j.
M. (Dobell).

This application should be made at intervals of one week, which may be increased as the disease succumbs to treatment, until two or even three weeks may be allowed to elapse between the applications I desire to speak with some positiveness concerning the use of the acetic acid, as the results which have attended its use, in my hands, have been uniformly favorable. As a rule, the irritation caused by it is but momentary, and passes away before the patient leaves the office, and the sense of relief follows immediately and continues. I should add that a patient ought not be allowed to leave the office until all irritation which has resulted from the treatment has been subdued. This can always be accomplished by the use of the solution given above, it being sprayed repeatedly into the cavity until the parts are made entirely comfortable. If this fails to relieve, a small amount of solution of morphia, grs. viij. to ℥ j., may be thrown into the cavity.

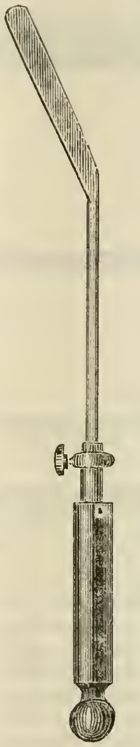

FIG. 4.—Probe for applying acetic acid to the nasal mucous membrane.

As before stated, the acetic acid is not a powerful escharotic, and many cases of nasal catarrh occur in which a more active method of destruction of the membrane will be demanded.

In these cases in which the hypertrophic membrane is largely developed, and in which the nasal cavity is much encroached upon, I know of no more efficient method of dealing with the disease than we possess in the use of the galvano-cautery.

The serious objection to its use is that it is not only a somewhat cumbrous affair, but it is an expensive instrument. Moreover, its use is attended with an amount of preparation and detail which renders this method of treatment oftentimes somewhat irksome. It is, however, an extremely valuable aid in managing the aggravated cases of catarrh.

I show a set of instruments which I have had constructed for my own use to fulfil the requirements of a light, easily manipulated handle, and an electrode mounted at such an angle as will still further facilitate the ease of manipulation, and also mounted in such a way as will enable the operator to follow by ocular inspection the movements of the heated wire, As will be seen, the circuit closer is immediately under the thumb when the instrument is held in the hand, and the current can be closed or opened at will. The electrode, mounted in the handle, has a vertical blade for cauterizing the face of the hypertrophied tissues.

When the thickened mass presents a rounded bulging tumor anteriorly, I find that more can be accomplished by making a linear incision along its face, cutting well down to the vascular layer of the membrane. The result of this is a cicatrix, which, in its contraction, reduces the mass far more than occurs from the superficial burning. The instrument by which this is done is shown at *a*. As will be seen, the cutting blade occupies but one side of the electrode, and is on a horizontal plane.

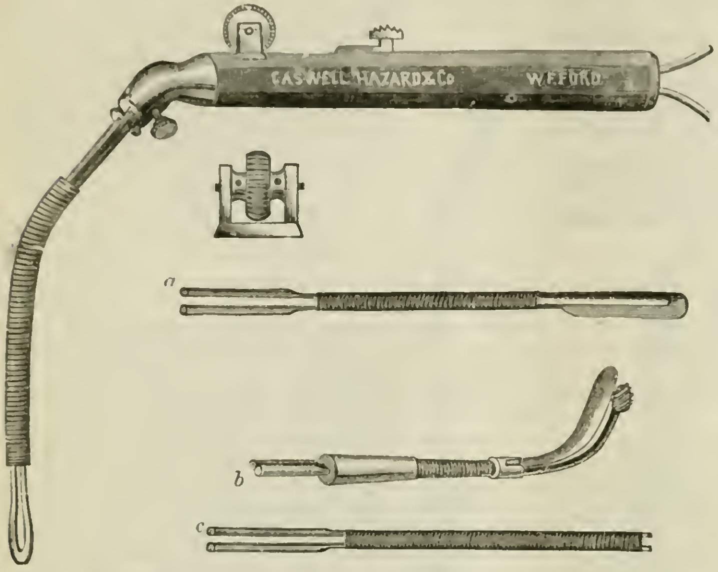

Fig. 5.—The writer's galvano-cautery instruments: *a*, knife for cutting laterally; *b*, electrode for cauterizing the pharyngeal vault; *c*, ecraseur.

In making these applications to the turbinated bone it is well that there should be some protection afforded to the septum. I know of no better device for this purpose than the little instrument shown in Fig. 6, devised by Dr. Shurley, of Detroit. As will be seen, it consists of an adjustable speculum, to one blade of which is fitted a movable slide. When the instrument is introduced, the ivory slide is passed into the cavity, and lying along the septum, affords a perfect protection to it from the heated electrode. Of course a different instrument is required for each nostril. For making application to the vault of the pharynx, the difficulty generally met with is in managing the soft palate, which lifts itself up, and of course is in danger of being burned by contact with the electrode. This may be obviated by tying the palate after the manner of Wales, or as demonstrated by myself last winter before the Academy. This, of course, consumes time, and is not always agreeable to the patient. I have devised the electrode shown in Fig. 6, for making this application without the necessity of tying the palate. As will be seen, it consists of a spiral wire, mounted at the proper curve for reaching the pharyngeal vault; over this there is fitted a hard-rubber hood. When the instrument is passed to the point at which it is desired to cauterize, it is pressed against the part, and emerges from its hood, when the circuit may be closed and the part burned. Before removing it the circuit is broken, when it is easily withdrawn. The palate, during the manipulation, is perfectly protected and saved from any injury.

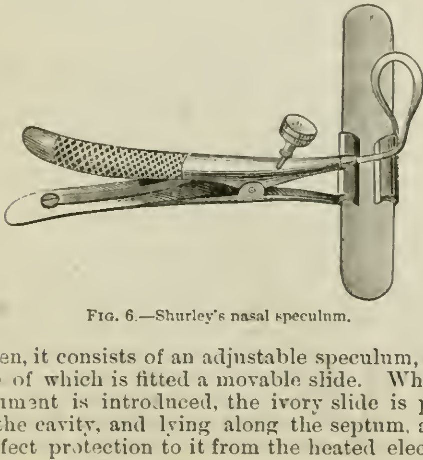

Fig. 6.—Shurley's nasal speculum.

In connection with this instrument there is shown a convenient little device for an ecraseur—Fig. 6, *c*. The double canula, being inserted in the handle, is fitted with a wire, which is wound upon a wheel, as shown in the cut mounted on the handle, and also in a separate figure in profile. The wheel fits in a slot on the handle, and can easily be removed when not used. This device is modified somewhat from that of Dr. Shurley.

In many cases of nasal catarrh there will be found a large sessile mass at the posterior termination of the lower turbinated bone. This may be so large at times as to almost completely fill the oval opening of the posterior nares. I show here (Fig. 7) a cut of a case from a drawing of Dr. Lefferts, which illustrates this not infrequent complication very graphically. This condition entails no little discomfort, and often distress, both from the occlusion of the nares, with interruption to nasal respiration, but also from the amount of secretion which arises from it. The methods of treatment alluded to are not competent to deal with this satisfactorily, as a rule.

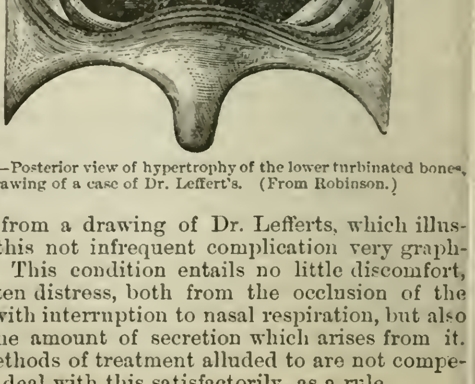

Fig. 7.—Posterior view of hypertrophy of the lower turbinated bones, from a drawing of a case of Dr. Leffert's. (From Robinson.)

The little instrument shown in Fig. 8 answers so perfect a purpose in removing these masses that it leaves nothing to be desired. It is the design of Dr. Jarvis, the assistant at the Bellevue Throat Clinic. It is an extremely simple form of wire ecraseur, and needs no description. Success in its use depends largely on the use of steel wire. The wire I always use is the No. 5 piano wire, which possesses a high degree of elasticity, together with a tensile strength which no tissue of the body can easily resist. I have, on several occasions, cut through dense fibrous tumors with this instrument.

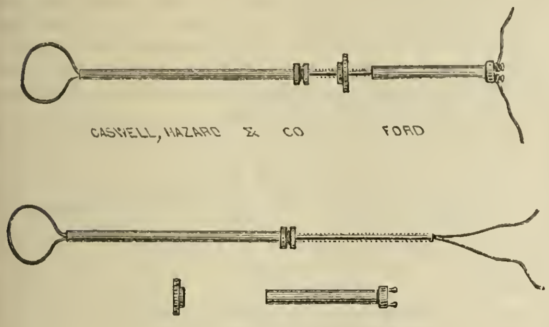

FIG. 8.—Jarvis's wire snare ecraseur.

In dealing with the condition above alluded to, the instrument is mounted with a loop, which an examination of the mass has shown to be sufficiently large to embrace it, and is then passed through the nares until the end of the loop passes the end of the turbinated bone, and is free in the upper pharynx. The loop having been bent slightly to one side before entering the nares will, by its own elasticity, slip over the mass, when it can be easily drawn into place and the tumefaction cut through. Of course there is considerable hemorrhage as the result of this, but if the operation be done slowly, a half hour or even an hour being consumed, it may often be done without loss of blood. If, however, hemorrhage does occur, a plug of absorbent cotton can easily be passed back and wedged between the cut surface and the septum, and allowed to remain until the following day, if necessary. The relief attending this operation is immediate and striking.

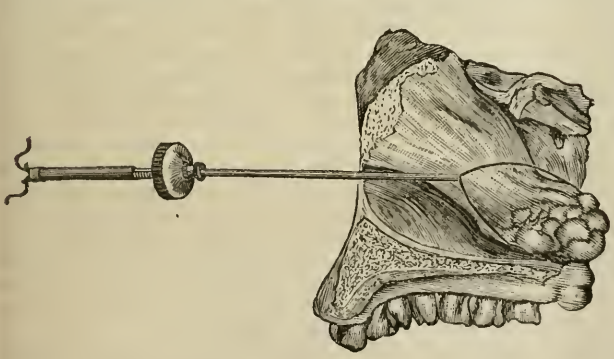

FIG. 9.—Lateral view of hypertrophy of the lower turbinated bone posteriorly, with snare in position.

The accompanying Fig. 9 gives a side view of this posterior hypertrophy. It is a drawing by Dr. Jarvis of a morbid specimen in his possession. There is also shown in the plate the snare in position for severing the mass.

A condition not unlike this at the posterior termination of the lower turbinated bone is frequently met with, though in a far less degree, at the anterior termination of the same bone. This consists in a rounded, puffy-looking mass, which encroaches on the lumen of the anterior nares, more or less completely filling it, and serving to obstruct materially the entrance of air.

A very simple device for removing this by means of the same snare ecrasure has been suggested by Dr. Jarvis. This consists of transfixing the mass from below upward and backward by a long, slender transfixion needle, mounted in a suitable handle. The loop of the snare is then passed over the handle of the needle, and subsequently over its point, when that portion of the mucous membrane which has been transfixed is cut through and removed. There is thus taken out a small mass about the size of a split pea. The cut surface heals kindly, and the result in my experience has been invariably to relieve the condition of stenosis. This, of course, accomplishes what the forceps does, but it does it in an almost painless manner, and with absolutely no bruising. The hemorrhage resulting is not great, and is easily controlled by a plug of cotton inserted for a few minutes.

It will be noticed that I have confined the subject of my remarks mainly to the nasal cavity proper, to the exclusion of the vault of the pharynx. As stated at the commencement of the paper, I regard the pharyngeal vault as a part of the nasal cavities. In nasal catarrh it undergoes the same changes which occur in the other portion of the passages. This consists in a true hyperplasia. In the pharyngeal vault, however, we find that there is an extremely rich distribution of glands, giving this part the name of the pharyngeal tonsil; hence we find that in this region the inflammatory process assumes a glandular character, and we have what, if it is of an aggravated form, is generally called adenoma of the vault of the pharynx. It is extremely rare, however, to meet with this condition developed to such an extent as to warrant the name. There is, as a rule, but a moderate glandular hypertrophy which occurs in connection with the hypertrophy extending throughout the nasal cavity. It is a mistake to suppose that this region is the source of a large amount of the secretion that characterizes nasal catarrh. The main source of the discharge is in the hypertrophied tissue over the turbinated bones, and the removal of this removes the prominent features of the disease. Still it will often become necessary to use measures directed to the pharyngeal vault, for this region is undoubtedly responsible for some of the untoward symptoms of the disease we are considering. I have already referred to the use of the galvano-cautery in this region. In my own experience we have no better method of coping with the disease there located.

To revert now somewhat and briefly. The use of the spray and douche were stated to be inefficient in more than controlling the disease. I should state that I invariably make use of the atomizer in all cases of nasal catarrh in my office work, and that I very frequently direct patients to use the douche at their homes.

The first step in all forms of treatment is the use of the carbolized alkaline fluid, the formula for which was given, to thoroughly cleanse the part of the accumulations of mucus. In addition to this I apply, by the same means, a mild astringent, such as tannin, gr. x.—xx. to ℥j., zinc. sulph., gr. x. to ℥j., potass. chlorat., ℈j. to ℥j., etc., in the order of preference. These measures are in most cases, however, only regarded as aids to the other measures already enumerated. The question arises as to which of the other measures to adopt in a given case. It is, of course, extremely difficult to formulate any rule for the selection of the special plan of treatment. If there is a mass at the posterior termination of the inferior turbinated bone, such as already described, and which will admit of or is sufficiently large to engage the snare, that instrument should be used. We possess no method of dealing with this condition comparable to it. If the mass anteriorly is large, rounded, and puffy, and occludes the nostril it should be transfixed and removed by the snare. It is a less painful and more efficient method than the cautery or the use of escharotics.

For those irregular and well-organized hypertrophies, which have existed for several years and which involve the continuity of the lower and middle turbinated bone, the galvano-cautery affords the best means of dealing with them.

If the disease has not existed for a long time, and the thickened tissues have not become hardened and dense by organization, the acetic acid will accomplish all that can be hoped for.

In milder cases, not characterized by any marked degree of hypertrophy, the use of atomized fluids will serve an excellent purpose. Unfortunately, these cases are not attended with any very prominent symptom, and they do not, as a rule, present for treatment.

The other remedies, such as chromic acid and nitric acid, I do not discuss further, for the reason that I have made but limited use of them, and in what I have said to-night I have endeavored to confine myself to personal experience.

Mention should be made before closing of one of the dangers which attends the use of any destructive agent in the nasal cavity; I refer to the danger of facial erysipelas. As we know, this disease may result from an apparent extension of an acute coryza. It is easy to understand, then, how any destructive agents used in the nasal cavity may be followed by the same unfortunate accident. The immediate result of the application of a caustic to the lining of the nasal cavities is to excite virtually an attack of acute coryza, with all the symptoms of that affection—such as intense congestion of the membrane, occlusion of the nares, profuse secretion, suffusion of the eyes, neuralgic pain, etc. This traumatic coryza would naturally tend to produce the facial erysipelas to a far greater extent than would the idiopathic coryza. The galvano-cautery is most at fault in this direction; next to this I should rank nitrate of silver, and then the nitric acid. Acetic acid, as far as I know, manifests no tendency in causing this accident. The only suggestion I can make in regard to the prevention of this accident is, that too much should not be attempted at one sitting, and that the cautery, if it be used, should not be allowed to remain in the cavity more than a few seconds at a time, and that the nares should be flooded with the douche or spray of the carbolized alkaline solution as soon as possible after the withdrawal of the cautery electrode or the escharotic.

There remains but one more unsettled question to which allusion should be made, and that is, can we cure nasal catarrh? This is an extremely difficult question to answer. I do not believe any physician, I care not what his abilities may be, or how much wisdom or skill his experience in the management of these cases may have endowed him with, is justified in promising to cure any given case of nasal catarrh of long standing; and by a cure I mean a genuine, complete, and permanent removal of all the symptoms. Many of us have cured cases of this disease, and as our experiences enlarge, as our special skill becomes better established, as our means of diagnosis extend, we will cure a still larger proportion of cases. But the ability to cure any given case involves the ability to cure all cases, and that we cannot do; and it reflects no credit upon our candor and conscientiousness if we promise to do what we know we are not safe in undertaking.

If, however, we bring to bear on each case all the means of diagnosis which are at present within our power, and doing away with that conception of nasal catarrh which regards it as an entity to be managed in a routine manner, but rather regarding it as a group of divers symptoms and conditions, each one of which is to be dealt with in a rational way, I believe that a large proportion of cases will become amenable to treatment, and most, permanently cured. That the same conditions which gave rise to the disease originally may not operate to induce a recurrence eventually of some of the symptoms, it is not safe to say; but that they need return in the full force of the original disease need not, as a rule, be expected.

In regard, then, to the question of the curability, I do not hesitate in making the assertion, and I make it advisedly: with our present means of diagnosis and knowledge of therapeutic resources in nasal catarrh, we can permanently remove most of the features of the disease which render it a present source of discomfort, and all those that constitute it a source of danger to the more vital portions of the respiratory tract.

Before closing, I should like to add one word in regard to our means of examination for the purpose of diagnosis. From what has been said, it will be easily inferred that I regard as of the first importance a thorough exploration of the nasal cavity, and the recognition of the special morbid condition which characterizes every portion of the mucous lining.

The early history of laryngoscopy was marked by the invention of what their inventors were pleased to call laryngoscopes. The one which has gained the widest notoriety is that known as Tobold's. This instrument is constructed on certain optical principles, I take it, known only to the inventor. I never have been able to detect them. I mention this instrument as one of a class, and to illustrate this point: no arrangement of lenses or reflectors is capable of increasing the rays of light. The concave reflecting mirror converges the rays and produces a disc of light more intense only so far as its area is less than that of the flame which is the source of the light. In its passage through lenses and reflection by mirrors much of the light, on the contrary, is lost. We are too apt to think that, having furnished our offices with a Tobold, our outfit is complete, and our means of diagnosis cannot be improved upon.

The head-mirror is preferable to all the laryngoscopes that were ever invented, and should always be used when feasible, while among the poorer methods of examination I should reckon Tobold's apparatus.

The head-mirror and the rays of the sun give such a perfect illumination that no portion of the nasal cavity need escape inspection by their use, and we should not lose the great advantages of this method of examination by resorting to the use of the so-called laryngoscopes.

It seems to me, oftentimes, that the eagerness with which we seize upon new ideas is something of a commentary on the still incompleteness of our art as physicians, and that our readiness to take up the newly-advanced and novel methods is only equalled by the tardiness and, oftentimes, almost sadness with which we lay them away with the other failures in medicine. The introduction of laryngoscopy has made prominent a number of co-ordinate new methods, among which are the spray, the douche, and the various illuminating devices. We may not really lay them away with the same regret that has followed many of their predecessors, but we will necessarily be compelled to abandon much of the hope with which they were first received.

REPORT OF CASES OF PHTHISIS

TREATED AT AIKEN, S. C., DURING THE SEASON 1879–80.

BY W. H. GEDDINGS, M.D.,

AIKEN, S. C.

(Continued from MEDICAL RECORD, October 30, 1880, p. 489.)

Case XLVIII.—Male, thirty-two years. (Dr. Forney, of Georgetown, D. C.) Mother died of phthisis. Patient began to cough in October, 1879, having had vague pains in the chest for some time previously. Lost twenty-five pounds.

January 29th.—Very pale, cheek bones prominent; great emaciation; pulse, 120; temperature, 100.5°. On the right side diminished resonance over the upper portion of the lung, from clavicle to the fifth rib, with an area of dulness in the axillary line. The respiration is feeble in front, and bronchial over the area of dulness on the side.

February 25th.—Pulse, 108; temperature, 99.7°. Much improved, has a good appetite, and has gained three pounds. The cough has become less frequent, but is to-day a little more troublesome in consequence of his having taken cold. Expectoration reduced to a half.

April 24th.—Pulse and temperature nearly normal. Had gained five and a half pounds, but lost two and a half during a severe attack of muscular rheumatism. Patient's general appearance is much improved, color good, and face fuller. There is dulness above and under clavicle, with diminished resonance as low as the second rib, instead of to fifth as at first examination. In the axillary line the dulness is much less marked. There is also dulness behind under the upper two-thirds of the scapula, which had probably escaped observation at the time of his first examination. Respiration over the affected portion of the lung is still bronchial.

Result.—Great improvement in general health, a gain of two and a half pounds, and probable diminution in the size of the area of dulness.

Case XLIX.—Male, twenty-five years, from Belleville, Ontario. (Dr. M. Sullivan.) Disease began in November, 1879, with bronchial catarrh; had night-sweats, and lost fifteen pounds.

January 31st.—Pulse, 102; temperature, 102°; weight, 150 lbs. Was quite ill during the journey south, and had to stop at Baltimore. Color pale. Expectorates about one ounce of muco-purulent matter. Tongue coated; cannot retain food. Right side dull in front from above clavicle to the fourth rib, with bronchial respiration. On the left side, dull from clavicle to second rib, with bronchial breathing. (Physical signs on the back were accidentally omitted.)

April 12th.—Patient improved steadily after the second week of stay in Aiken, and now looks quite robust; has a fresh, ruddy color, and now weighs 165 lbs., a gain of fifteen pounds since his arrival. Pulse, 80; temperature, 98.5°. Coughs only after a hearty laugh or some other unusual exertion. The dulness on the right side is reduced to a limited area above the clavicle, with diminished resonance under that bone. Behind there is diminished resonance over a small space between the scapula and spinal column. Respiration in front is vesicular; behind, bronchial over a very small area. On the left side the dulness has disappeared entirely, and the respiration is everywhere vesicular.

Result.—Complete arrest of the disease, with a gain of fifteen pounds, and entire disappearance of all physical signs of disease in one lung and partial clearing of the other.

Case L.—Male, 41 years, New York. (Dr. Horton.) Hereditary predisposition, several maternal aunts and uncles having died of phthisis. Disease is said to have commenced with chills and fever in the winter and spring of 1879. Cough began in June, had sweats in July and August, and gradually lost ten pounds.

February 7th.—At the time of his arrival in Aiken his weight was 141 lbs., but he has since gained twelve pounds. Color somewhat pale. Expectorates two ounces of muco-purulent matter.

Left side.—Dull from clavicle to the fifth rib in front, and under the upper third of the scapula behind, with feeble respiratory murmur, and loud, moist râles. On the right side no dulness, but about the middle of the lung the respiration is jerking and somewhat bronchial in character. Has dyspepsia and digests oil with difficulty.

April 13th.—Pulse, 80; temperature, 99.3°. Owing to repeated attacks of gastric catarrh, the patient has probably lost a few pounds of the twelve pounds gained during the first weeks of his residence in Aiken. He coughs much less, and the expectoration is reduced from two ounces to half an ounce. On the left side the dulness extends in front to the fourth rib; only a slight diminution in that situation. Posteriorly, the improvement is more marked, the dulness being confined to the space above the spine of the scapula. Respiration not noted.

Result.—A marked improvement; a gain of at least ten pounds, and a reduction in the size of the infiltration.

Case LI.—Male, twenty-eight years. (Dr. George H. Humphreys, New York.) Had hemorrhages at long intervals during the summer of 1879, with cough and night-sweats. Lost eight pounds.

February 10th.—Color pale. Expectoration small in quantity and muco-purulent in character. There is dulness on the right side above, under and below the clavicle in front, and between the scapula and vertebral column behind. In addition to this, there is a limited area of dulness in the axillary line. Respiratory murmur is feeble.

March 10th.—Pulse, 76; temperature, 99.5°. Much improved. Color good. Coughs only in the evening, and without expectorating. Has gained two pounds There is no change in the physical signs, but over the back and side there is no trace of the dulness observed at the first examination.

May 1st.—Patient has continued to improve, and now presents the appearance of a man in perfect health. Flesh firm, color good. Walks eight miles without feeling fatigued. He has gained two pounds weight, and has no cough. The only evidence of disease left is slight dulness under the right clavicle, with harsh respiration, and audible experium at the apex on that side.

Result.—Arrest of the disease, as evidenced by cessation of the hemorrhages and sweats; disappearance of the cough, increase in weight, and the absence of most of the physical signs observed at the first examination.

Case LII.—A married lady, twenty-three years of age, a patient of Dr. Fleming, of Pittsburg. She suffered in the fall and winter of 1876 with bronchial catarrh and loss of flesh; grew better in 1877, but relapsed in the fall of the ensuing year. Has lost fifteen pounds.

February 12th.—Pulse, 120; temperature, 100°; weight ninety-five pounds; looks very frail. Expectorates about one ounce in twenty-four hours. Over the left front there is dulness from the clavicle to second rib, with crepitant râles. Dull behind (extent not noted), with bronchial respiration. On the right side extensive dulness extending from clavicle to fifth rib, with bronchial breathing and prolonged experium. Posteriorly, on this side, there is dulness under the lower third of the scapula and between that bone and the column; respiration bronchial.

March 16th.—Has gained one pound and the face appears fuller. No change in other symptoms.

May 8th.—Pulse, 108; temperature, 99.5°. Reports that she coughs only a little in the morning, and that she is much stronger. Has not weighed, but has evidently increased in weight. The symptoms afforded by physical examination were very hastily noted and too imperfect for reproduction. They show, however, some diminution in the extent of the diseased surface.

Result.—Improvement in general health, slight increase in weight, and some diminution in the extent of the infiltration.

Case LIII.—A young lady of twenty years, patient of Dr. Van Dyck, of Philadelphia. Disease began in April, 1879, with persistent hacking cough and gradual loss of flesh. In September of that year she had an attack of pneumonia, irregular in style, but with the sputa characteristic of that disease. Has lost fifteen pounds.

February 16th.—Pulse, 112; temperature, 100.5°; weight, 130 lbs.; color pale. Over the right front, dull from the clavicle to the third rib, also over the back, as low as the angle of the scapula. Bronchial breathing, with prolonged experium, together with moist râles audible over the whole of that side. On the left side no dulness, but harsh respiration in front and bronchial over a small area behind. Can sleep only on the left side, and expectorates one ounce of muco-purulent matter.

March 15th.—Pulse, 100; temperature, 101.3°. Has lost one and a half pound. Extent of dulness unchanged, but there is cavernous respiration under second rib on the right side.

April 29th.—Color improved; is somewhat stronger; has an excellent appetite, and enjoys undisturbed rest at night. Weighs 117 lbs., a loss of thirteen pounds. The area of dulness is unchanged in front but extends an inch lower down behind.

Result.—Improvement in general health, but extension of the disease, with a loss of thirteen pounds in weight.

Case LIV.—A young man of twenty-four years, a patient of Dr. Joseph Stedman, of Boston, with hereditary tendency to phthisis on the father's side. During an attack of typhoid fever in December, 1879, chronic pneumonia developed itself at the apex of the right lung, which in the course of the succeeding two weeks rapidly extended through the whole of the upper lobe and a portion of the lower. Emaciated rapidly and had night-sweats.

February 24th. Pulse, 120; temperature 102.3°. Looks pale, and is quite feeble, being unable to walk even very short distances without becoming fatigued. On the right side an extensive area of dulness, extending in front to the fourth or fifth rib, and behind as low as the angle of the scapula. The respiration is distinctly bronchial over the area of dulness, and somewhat cavernous below the clavicle; experium prolonged. Vocal fremitus increased.

April 25th.—Pulse, 100; temperature, 100.4°. Patient looks a little better and his general health is somewhat improved, but the local symptoms remain as at first examination.

Result.—The result in this case, *i.e.*, prolongation of life, was fully as good as the grave nature of the case would admit of. The great extent of the disease and its rapid development in a young subject, after a long and exhausting illness, precluding all hope of a more favorable issue.*

Case LV.—A young man from Baltimore, who has had phthisis for several years, and has twice visited Aiken on that account, having each time derived marked benefit from his residence there. Becoming careless, and disliking the prolonged absence from home, he remained in Baltimore until the latter part of February, when increase of cough and renewed loss of flesh induced him to start for Aiken.

February 27th.—Pulse, 100; temperature, 98.5°; weight, 136½ lbs.; color pale. On the left side there is dulness in front, extending from the clavicle to the fifth rib, also in axillary line; posteriorly the lung is still resonant. The respiration is feeble in front with abundant mucous râles behind. On the right side there is a small area of dulness under and below the clavicle, the respiration over the upper portion of that lung being bronchial in character, with prolonged expiratory murmur.

March 9th.—Pulse, 96; temperature, 99.8°. Looks a little better, and has gained four pounds.

April 23d.—Has been very imprudent, and has exposed himself in the most reckless manner. Looks badly; has lost one and a half pound and is evidently much worse. The dulness extends over the greater portion of the left lung, and there is little or no movement of the thorax on that side during respiration.

Result.—Extension of the disease.

Remarks.—The marked improvement which took place during his former visits to Aiken justify the assumption that the result would have been different if this patient had returned in due season and had taken proper care of himself.

Case LVI.—Male, thirty-four years. (Dr. Haddock, of Beverly, Mass.) Began to cough in September and had pleuritic pains on the right side during the fall months. Expectoration has at times been tinged with blood. Has lost thirty pounds. Has been three weeks in Aiken, and during that time has improved in strength and has gained three pounds.

February 28th.—Pulse, 84; temperature, 99.3°; weight, 140 lbs. Right side dull in front from the clavicle to the third rib, also behind under the supra-spinous fossa. Respiration is much feebler than on the left side.

---

* This patient declined rapidly after leaving Aiken, and died in the early part of June.

March 16th.—Pulse, 100; temperature, 103°. About ten days ago the patient had a severe attack of hyperæmia of the liver, with considerable pain and some dyspnœa. Is much reduced and has evidently lost ground.

April 30th.—Pulse, 96; temperature, 98.9°; weight 140. Coughs only in the morning, or after an indigestible supper, and has no expectoration. His color is good and his general appearance healthy. The dulness in front has receded to the second rib, a gain of one rib. Over the back the area of dulness is unchanged, except that there is a small dull space between the scapula and column. The respiration over the apex, both front and back, is bronchial.

Result.—General improvement, with some diminution in the amount of dulness, and a gain of three pounds.

Remarks.—This patient was gaining rapidly until prostrated by the hepatic complication, which caused him to lose much that he had previously gained.

Case LVII.—An Irishman, forty-three years. (Dr. Wright, of Indianapolis.) Has had pulmonary disease since 1870. Had repeated hemorrhages in 1877-78, lost thirty-two pounds in weight and has had night-sweats. In addition to disease of the lungs, the patient has had intermittent and remittent fevers, rheumatism and dyspepsia. Came to Aiken in January, improved for the first two weeks, gaining three pounds, but since that time has made no progress.

February 28th.—Pulse, 112; temperature, 99.5°; weight, 130 lbs. On the left side, dull in front, from the clavicle to the fourth rib sensitive on percussion, loud, moist râles over the upper portion of the chest. Posteriorly the dulness extends down two-thirds of the scapula, over which surface mucous râles are everywhere audible. On the right side there is nothing abnormal in front, but behind there is a small amount of dulness, with bronchial respiration, between the lower third of the scapula and column. Laryngoscopic examination reveals extensive ulceration of the vocal cords and congestion of other parts of the larynx.

Remarks.—This patient remained two months longer at Aiken, and, as would naturally be expected from the character and extent of the disease, failed to derive any benefit.

Case LVIII.—A married lady, thirty-one years old, a patient of Dr. H. A. Johnson, of Chicago. Mother and aunts died of consumption, and also one brother. Has had cough during the winter for several years, but last October it became persistent and was accompanied with night-sweats and emaciation.

February 28th.—Pulse, 100; temperature, 101°. The patient, who is greatly emaciated, presents a decidedly cachectic appearance and suffers with dyspnœa upon the slightest exertion. The amount of dulness does not correspond with the gravity of the other symptoms, being confined to a limited area above and under the right clavicle. The respiration over the upper portion of that lung is decidedly bronchial in character, with prolonged experium. On the left side the only abnormal sign is a loud expiratory murmur.

March 23d.—Pulse, 96; temperature, 98½°. Has had one acute exacerbation, but now feels better as well as stronger than when she first arrived.

May 4th.—Pulse, 112; temperature, 103°. Is evidently failing. The dulness is now plainly perceptible under the supra-spinous fossa on the right side. The disease has also made rapid advance in the right lung, the dulness on that side extending from the clavicle to the fourth rib.

Result.—Extension of the disease.

Remarks.—The cachectic appearance of the patient, her extreme emaciation and great weakness, with evidence of disease in both lungs, precluded all hope of a more favorable result.

Case LIX.—A young lady, twenty-six years old, a patient of Dr. W. W. Johnson, of Washington, D. C. The disease began with cough in September, 1879, followed by loss of weight and hemorrhage in December. Has also had night-sweats. Has lost nine pounds. She arrived in Aiken seven weeks ago and has improved, having already gained eight pounds.

March 2d.—Pulse, 108 (under excitement); temperature, 98½°. Looks quite healthy. Physical examination reveals dulness on the left side extending from the clavicle to the fourth rib, and under the upper portion of the scapula.

April 20th.—The improvement noted above continued until the middle of March, when she was unfortunate in contracting a severe cold, during which she suffered with severe pleuritic pains and lost her voice. Up to that time she had gained twelve pounds. She has now recovered from the attack and is again improving.

Result.—Great improvement checked by an acute attack, with a gain of about nine pounds. Change in physical signs not stated. Not having seen her until several weeks after her arrival, I am unable to state what alteration has taken place in the extent of the infiltration.

Case LX.—Married lady, twenty-nine years. (Drs. Conrad and Leaming, of New York.) Disease began with a "cold" in September; cough has been persistent since that date. Expectoration occasionally tinged with blood.

March 2d.—Pulse, 92; temperature, 98½°. Dulness over upper portion of the left lung in front and under the supra-spinous fossa behind. Respiration feeble on that side, with increased vocal fremitus.

April 27th.—Improved during the first weeks, gaining a few pounds. Since then there has been a great deal of gastric disturbance, occasional fever, and some pain in the lung. No change in the physical signs other than the presence of a few moist râles.

Result.—Leaves Aiken in about the same condition as when she arrived, the gain during the first weeks of her residence there having been counterbalanced by subsequent loss.

Case LXI.—A young lady, twenty years old. (Dr. Henderson, Brooklyn, N. Y.) The disease began with an attack of hæmoptysis in May, 1879, which recurred again in July and September, and was very profuse in December. Has had steady cough since September, and has lost six pounds. Has been two months in Aiken, and did well until a few days ago, when the cough became suddenly more frequent, and was attended with marked increase of temperature.

March 4th.—Pulse, 120; temperature, 100.4°. Looks pale and sick; tongue coated; no appetite, and complains of headache. Right front dull from the clavicle to the third rib, under the supra-spinous fossa, and between the scapula and column. Respiration is bronchial in character.

March 22d.—Is quite hoarse; has some pleuritic pain, and is feverish, all the result of exposure for several hours in a damp locality.

April 23d.—Has gradually recovered from the attack in March, which proved to be quite severe. Up to that time she had gained ten pounds. Her present weight is 128 lbs., which is four pounds greater than when she arrived. Physical signs unchanged.

Result.—Improvement in general health and a gain of four pounds in weight.

CASE LXII.—A married lady, thirty-two years. (Dr. J. Solis Cohen, Philadelphia.) Hereditary predisposition to phthisis. Cough began in September, 1879, followed by laryngitis in October. Aphonia from that date until her arrival in Aiken, when her voice returned, and is now quite clear.

March 5th.—Pulse, 94; temperature, 99.1°. Color good; cough very troublesome. On the right side dulness from the clavicle to the fourth rib and over upper third of the scapula. Respiration loud and bronchial in character, somewhat cavernous, with increased vocal fremitus behind. Laryngoscopic examination reveals erosion of both vocal cords, which are quite red near their insertion into the arytenoid cartilages.

April 24th.—Pulse, 92; temperature, 99.5°. General improvement; has gained one pound, and coughs less. The dulness in front has receded to the third rib. Physical signs in other respects unchanged.

Result.—Improvement in general health. Slight increase in weight. Some diminution in the extent of the infiltration, and recovery of voice, after four or five months of more or less complete aphonia.

CASE LXIII.—A married lady, forty-five years. (Dr. Ralph Walsh, Washington, D.C.) Hereditary predisposition, father, mother, brothers, and sisters having died of consumption. Has been in feeble health for several years, and has had cough since November, 1878. Has had one hemorrhage. Loss of weight, twenty pounds.

March 12th.—Pulse, 92; temperature, 101.6°. General appearance decidedly cachectic. Expectorates about two ounces of thick muco-purulent matter. On the right side there is dulness above and under the clavicle, with diminished resonance as low as the third rib. Behind, the dulness extends over the upper two-thirds of the scapula. Respiration both front and back decidedly bronchial, and in some places cavernous in character. On the left side there is also an area of dulness, extending in front from the clavicle to the second rib, and occupying behind the space corresponding with the supraspinous process. The respiration on that side bronchial, with an occasional ronchus.

This patient improved, but, owing to her being suddenly called home, I had no opportunity of again examining her. With a view to completing the history of the case, I wrote to Dr. Walsh to ascertain her condition. He writes to me, under date August 29th, that he "firmly believes that the trip to Aiken has so far saved her life," and that he proposes to have her return next season.

Result.—Marked improvement in general health; changes in physical symptoms not noted.

CASE LXIV.—Male, twenty-two years. (Dr. J. S. Lothrop, Boston.) Lost a brother with pulmonary phthisis. Disease began in March, 1879, with cough and emaciation. Lost eleven pounds, but subsequently regained eight pounds.

March 13th.—Pulse, 84; temperature, 98½°; weight, 125 lbs. Expectoration small in quantity, and of late occasionally streaked with blood. Over right front dulness above and under the clavicle. Respiration feeble, with prolonged experium. Behind there is dulness under the supra-spinous fossa, the respiration being as in front.

April 23d.—Patient has had an exacerbation of his disease, with fever, pleuritic pain, and a loss of four pounds in weight. From this he soon rallied and now weighs 128 lbs., which is three pounds more than at the time of his arrival. The infiltration is slightly increased in size, there being diminished resonance to the second rib in front, and two-thirds down to scapula behind.

Result.—Extension of the disease at first, with marked improvement afterward; the loss during the acute attack being more than counterbalanced by his subsequent improvement.*

CASE LXV.—Male, thirty-two years. (Dr. Edwin Powell, Chicago.) Disease began with bronchial catarrh in the summer of 1878. Lost twenty pounds, of which he afterward regained ten. Has had fever, and occasional sweats. Went to Colorado in November, 1878, and remained there until August, 1879, lost his cough, but did not increase in weight. Has been hoarse since September, 1879. Cough reappeared after his return to Chicago.

March 16th.—Coughs but little, but when he does the expectoration is quite profuse. Weight, 130 lbs. Physical examination—the notes of which are rather incomplete—reveals a small infiltration at the apex of the right lung, as evidenced by dulness and bronchial respiration.

April 28th.—Pulse, 60; temperature, 98.9°. Weight, 136 lbs, a gain of six pounds. Coughs very little (a short hack two or three times a day), expectorating a small quantity of matter, which is gradually diminishing in quantity. Flesh firm; strength much improved. Walks two and a half miles without fatigue. His appearance is that of a perfectly healthy man. Slight dulness under outer portion of the clavicle, under the supra-spinosis fossa, and between that portion of the scapula and the vertebral column. Respiration bronchial. Hoarseness greatly improved.

Result.—Great improvement in general health, diminished cough and expectoration, and an increase in weight of six pounds. Voice much clearer.

CASE LXVI.—Male, twenty-one years. (Dr. Loomis, New York, consulting physician.) Had cough throughout the winter of 1878–79, which disappeared during the summer, but returned in December, after taking a severe cold. Had an attack of hæmoptysis in January, 1880. Has lost twenty pounds, and has had night-sweats.

March 18th.—Pulse, 120; temperature, 100.7°. Weight, 115 lbs.; appearance cachectic; expectoration two ounces. There is an extensive area of dulness, with feeble respiration to the outer side and below the angle of the right scapula.

May 26th.—Pulse, 84; temperature, 99.8°. Weight, 130 lbs., a gain of fifteen pounds. Coughs less, and looks much better, has a good appetite, and is able to walk three miles without fatigue. Marked depression of the thorax below the right clavicle. Dulness as at first examination. Respiratory murmur feeble and indistinct.

Result.—General improvement, and a gain of fifteen pounds.

CASE LXVII.—Male, twenty-five years, from New York. Has been treated by a homœopathic practitioner of that city. No hereditary predisposition. Is said to have had malarial fever in August, 1879. This was followed by cough, and loss of weight to the extent of seven pounds. Has had night-sweats. Expectoration has been occasionally tinged with blood. He arrived in Aiken late in January, and has been steadily improving ever since. The night-sweats have ceased, and he has regained the seven pounds which he lost in New York.

---

* This patient was again under my care during the summer months at Bethlehem, N. H., where his improvement was both rapid and continuous.

March 30th.—Pulse, 88; temperature, 99.2°. Color good. Expectorates two ounces.

Right side.—Dull under the clavicle and first rib, with diminished resonance under the upper portion of the scapula and in the interscapular space. In the latter situation the breathing is bronchial.

May 8th.—Patient did well until two weeks ago when he was taken with diarrhœa. He reports that he consulted a physician, who informed him that it was his liver which was at fault, and gave him powders (probably calomel), during the administration of which he grew rapidly worse. The patient is much changed for the worse and presents a miserable appearance. His pulse is 96, and his temperature 102°. Is pale, and is exhausted by the slightest exertion. There is dulness over the entire front of the right lung, with bronchial breathing. Under proper treatment he improved sufficiently to start for home during the following week.

Result.—Great improvement during the first three months, with a gain of seven pounds, followed by relapse and rapid extension of the disease.

CASE LXVIII.—A young man of about nineteen years, from Boston. (Dr. Knight, consultant.) Has had cough since last spring, attended with loss of flesh. Spent the summer at Bethlehem, N. H., where he held his own. Returned to Boston in the fall, and while there lost ground. Came to Aiken a month ago and has been improving ever since. Has gained ten pounds since his arrival.

April 6th.—Pulse, 112 (is very nervous); temperature, 100.9°. On the left side there is a dull area extending in front from the clavicle to the seventh rib, and behind as low as the angle of the scapula. The respiration is distinctly bronchial in character.

April 30th.—Pulse, 104; temperature, 100.7°. Color improved. Weighs 146 lbs., a gain of two pounds since last examination, and of twelve pounds since his arrival. Coughs less, expectoration reduced in quantity and with a greater proportion of mucus. In front the dulness has receded to the fifth rib, but this is counterbalanced by extension behind, the lower border of the area of dulness now reaching to one inch below the angle of the scapula.

Result.—Great improvement in general health, with a gain of twelve pounds.

CASE LXIX.—A young lady, twenty-eight years, a patient of Dr. Opie, of Providence. Several relatives on the maternal side, including the patient's mother, have died of phthisis. Had cough during the winter of 1878 and 1879, but was free from it during the ensuing summer. It returned again in the fall after an attack of "nervous prostration" and has persisted ever since. Has lost a great deal in weight, but does not know how much. Sputa have been occasionally tinged, and has also suffered with night-sweats. Has improved a great deal since her arrival in Aiken six weeks ago, eating and sleeping well, increasing in weight, and coughing less.

April 17th.—Pulse, 100; temperature, 99.5°; weight, ninety pounds; expectorates half an ounce. Over the right front, which is very sensitive on percussion, there is no marked dulness, but the respiration is decidedly bronchial. Posteriorly there is dulness under the scapula and between that bone and the column. The respiration over that region is bronchial.

May 5th.—Pulse, 80; temperature, 99.8°. Has gained eight pounds, and has a healthy color. Coughs but little, and does not expectorate more than a drachm. (I did not have an opportunity of examining her before she left Aiken, but on meeting her a few months later at Bethlehem, N. H., I found she had been entirely free from cough for several months. The bronchial respiration had disappeared, leaving only a little roughness. The area of dulness behind, although still present, was much more limited than when I first examined her.)

Result.—Marked improvement in every respect, with subsequent arrest of the disease.

TABULAR STATEMENT OF CASES OF PHTHISIS TREATED AT AIKEN, SOUTH CAROLINA, DURING THE WINTER OF 1879–80.

Case No.	Lung affected.	Term of residence in Aiken.	Result.	Increase in weight.
XXXII	Left.	5 months.	Improved.	16 lbs.
XXXIII	Left.	1 month.	Grew worse.	0
XXXIV	Right.	4 months.	Died.	0
XXXV	Right.	3 months.	Improved.	Not noted.
XXXVI	Right.	5 months.	Grew worse.	0
XXXVII	Right.	2 months.	Died.	0
XXXVIII	Right.	5 months.	Improved.	8 lbs.
XXXIX	Left.	3 months.	Grew worse.	0
XL	Left.	3 months.	Grew worse.	0
XLI	Right.	4 months.	Improved.	4½ lbs.
XLII	Both, with laryngeal complication.	3 months.	Grew worse.	0
XLIII	Right.	10 years.	Arrest.	Not noted.
XLIV	Right.	4 months.	Arrest.	2 lbs.
XLV	Both.	4 months.	Grew worse.	7 lbs.
XLVI	Right.	4 months.	Arrest.	4 lbs.
XLVII	Both.	3 months.	Arrest.	20 lbs.
XLVIII	Right.	3 months.	Improved.	2½ lbs.
XLIX	Both.	3 months.	Arrest.	15 lbs.
L	Left.	3 months.	Improved.	10 lbs.
LI	Right.	3 months.	Arrest.	2 lbs.
LII	Both.	3 months.	Improved.	Not noted.
LIII	Both.	3 months.	Grew worse.	0
LIV	Right.	2 months.	Unchanged.	0
LV	Both.	2 months.	Grew worse.	0
LVI	Right.	4 months.	Improved.	3 lbs.
LVII	Both, with laryngeal complication.	4 months.	Unchanged.	0
LVIII	Both.	2 months.	Grew worse.	0
LIX	Left.	4 months.	Improved.	9 lbs.
LX	Left.	2 months.	Unchanged.	0
LXI	Right.	4 months.	Improved.	4 lbs.
LXII	Right.	3 months.	Improved.	1 lb.
LXIII	Both.	2 months.	Improved.	Not noted.
LXIV	Right.	2 months.	Improved.	3 lbs.
LXV	Right.	3 months.	Improved.	6 lbs.
LXVI	Right.	3 months.	Improved.	15 lbs.
LXVII	Right.	3 months.	Grew worse.	0
LXVIII	Left.	2 months.	Improved.	12 lbs.
LXIX	Right.	2 months.	Arrest.	8 lbs.

SUMMARY.

	Season 1878–79.	Season 1879–80.	Both Seasons.
Arrested	6	7	13
Improved	13	16	29
Unchanged	4	3	7
Grew worse	7	10	17
Died	1	2	3
	31	38	69

It will be seen by the above summary that there is a remarkable degree of uniformity in the results of the two seasons. As "arrested" are classed only those cases in which the cough has ceased, in which there was no fever or other evidence of activity in the disease, and in which the increase in weight and general appearance of the patient indicated that for the time being, at least, he was restored to health. Many of these cases might safely be regarded as permanently *cured*, but as the comparatively short time that most of them have been under observation precludes the possibility of determining the permanency of the arrest, I have concluded to adopt a more modest but safer term to signify that the disease has been brought to a standstill. Many of the local manifestations of disease, such as depression of the thoracic walls, dulness on percussion, etc., are still present, to a greater or less extent, in most of these cases, nor is it to be expected that they will ever disappear.

I have seen cases that have enjoyed good health uninterruptedly for twenty or thirty years in whom the dulness was as distinct as when the process was at its height. Case XLIII., where after ten years of good health the dulness is still present, affords a good example of this fact.

Progress of Medical Science.

Multiple Sympathetic Affections Caused by the Presence of Intestinal Worms.—Dr. Guermonprez (*Journal des sciences méd. de Lille*, July, 1880) reports this curious case: A girl, eleven years old, without morbid antecedents, and lacking all hereditary taint, had occasionally passed some long round worms (*ascaris lumbricoides*), but in less number than many other children living in the same locality. Her father noticed that her intelligence began to weaken, and that she showed peculiarities of character. She would tear her clothes, run away from home, or grow morose, irritable, and perverse. Her memory began to fail her. At irregular intervals, and without appreciable cause, these psychical disturbances became even more marked. Her nights would then be spent in restless agitation. This lasted about a month. The restlessness was at that time constant; when about, she must walk; if stopped, she stamped her feet, kicked with irregular movements, gave no answers. When seated, her limbs were in perpetual motion. There were moments of apparent calmness, but also decided exacerbations. Hearing was lost, and vision became impaired. In addition, speech forsook her, and her face was distorted by grimaces. Frequently she cried, at other times she appeared to be viciously inclined, pursuing her sister with a knife. Again, she would be the victim of actual hallucinations. The bodily functions were regularly performed, but she had grown somewhat thinner. Opium, chloral, bromide of potassium, and baths, all proved unavailing in the cure of her malady. At length a vermifuge was tried, and thirty-seven worms were passed. On the following day the nervous condition was visibly improved. In twelve days she passed about eighty worms, and as she got rid of them her agitation subsided and her intelligence returned. In two months she had completely recovered, and the cure has remained undisturbed for the two years since that time.—*Gazette méd. de Paris*, August 21, 1880.

Embolism of the Abdominal Aorta above the Iliac Bifurcation.—Dr. Deroyer reports the following case: A primipara, twenty-two years old, having passed through a normal pregnancy and delivery, developed a marked febrile movement on the third day after the latter event. She was then giving the breast to her child, but the condition of the abdominal organs gave no clue to the fever. Antipyretic treatment soon controlled the fever, but three days later it returned, together with painful sensations in the left iliac fossa. After several days the febrile movement again ceased. The patient being constipated a castor-oil injection was given. A difficult evacuation followed, and during the efforts of defecation she suddenly uttered a loud cry, and complained of a severe pain in her abdomen. The physician arriving soon after found her with an anxious expression of countenance, breathing rapidly, and with a pulse of 120. No tympanitis, no abdominal tenderness, and normal lochial discharge; uterus and appendages showed no signs of inflammatory action. Her condition fluctuated for several days between pain with fever, and complete freedom from all morbid manifestations. Then one night the doctor was suddenly summoned, and found the patient suffering intolerable pains in both legs, together with a feeling of numbness there. In exploring the condition of the circulation it was found that both femoral arteries lacked a pulse. The abdomen being supple, abdominal pulsations could be readily felt, extending as far as the umbilicus, where they ceased. Hence that point corresponded to the seat of obstruction. It was determined to try energetic pressings and rubbings along the course of the aorta. The pain subsided somewhat under this treatment, but on the following morning the femoral pulse was still absent. A repetition of yesterday's experiment was followed by the reappearance of the pulse, and was repeated as often as it began to flag. Spots of discoloration, however, made their appearance on both legs. The pulse seemed permanently re-established on the left side, but was again absent on the right. The frictions were followed by a reappearance, for a short time, of the pulsations, but at last they invariably ceased soon after this manipulation. Gangrene at length supervened, and the patient died. An autopsy was not permitted.—*Gazette des hôpitaux*, Aug. 10, 1880.

Anthrax Acquired on Pasturage.—Dr. Poincaré reports the following, which is of interest from the standpoint of experimental pathology. On an isolated farm the cattle were attacked by anthrax, and nineteen animals perished within three weeks. A veterinarian observed that the grass of the meadow serving as pasturage ground was always wet with a marshy liquid. He thought that this might contain the germs of the disease, and advised the farmer to seek new pasturage ground. Another veterinarian's advice, to the effect that the animals should not be allowed to return to their stable, being followed, three more beasts died. Dr. Poincaré received some of the marshy fluid, together with blood from one of the dead animals. Both contained similar bacteria. Some of the boggy fluid having been hypodermically injected into a guinea-pig, the latter soon fell sick, and died in a few days after the injection. The blood of the animal showed the parasitic alteration described by Davaine, and being introduced subcutaneously into a second guinea-pig, caused the death of this one on the same day. The autopsy and microscopic examination demonstrated that the disease was anthrax.—*Gazette méd. de Paris*, August 21, 1880.

Mastich in the Treatment of Uterine Cancer.—Dr. O. Jennings has tried this drug as a substitute for the Chian turpentine, in six cases of uterine cancer, and while he has, of course, been unable to effect a cure, the treatment was nevertheless, in several instances, followed by a decided improvement in the general condition of the patients. The drug (turpentine of *Pistacia lentiscus*) was administered in connection with flowers of sulphur, and in the form of pills, the proportion being six parts of the turpentine to four of the sulphur. Eight pills, each one containing 15 centigrammes of the turpentine, were given as a daily dose. In the first case, after ten days of such treatment, the local signs were but slightly changed; still there was a marked improvement of the patient's general health, the appetite was better, and the vaginal discharge had considerably diminished. The existing painfulness in the lumbar and hypogastric regions was also much lessened. In the second, the drug caused some initial vomiting, but tolerance was soon established. Here, also, the patient was notably improved. In the third case, the improvement was still more marked, so that the patient insisted on leaving the hospital, being now in a condition of absolute painlessness, whereas on admission she had suffered intensely. In the fourth case, the pains were not controlled, but the discharge diminished during the administration of the drug. The fifth case showed no local amelioration after one month's trial of the turpentine, though the general health of the patient continued to be satisfactory during all this time. In the sixth and last case the drug increased the already existing tendency to vomit, and after one week she refused to continue with the medicine. There was no improvement. Finally, the writer says that these trials certainly had encouraging results, and in view of the difficulty of obtaining pure Chian turpentine, ordinary mastich deserved to be further tried.—*La Tribune médicale*, Aug. 15, 1880.

Influence of the Epileptic Attacks on Weight of Patients.—Dr. Kowalewsky read a paper bearing the above title before the twenty-first convention of Russian naturalists and physicians. He divides his patients in five groups: 1, chronic grand mal, with frequent attacks (twenty-five cases); 2, recent (one to one and a half years) grand mal, with few attacks (forty-seven cases); 3, petit mal (seven cases); 4, status epilepticus (about ten cases); 5, epilepsy with mania: *a*, with convulsions, and *b*, without convulsions (number of these cases not stated). Patients were kept on the same diet, were weighed at regular hours, were not made to do any hard work, and all suffering from insomnia, fever, etc., were excluded: 1. In old cases of grand mal, the loss in weight, after each paroxysm varied from one to two pounds. 2. In recent cases of grand mal the loss was from three to twelve pounds, but more commonly, three, five, and four pounds. One patient, who was free from the attacks during six months, after two consecutive paroxysms lost nine pounds. 3. Attacks of petit mal were also followed by loss in weight, but to a lesser degree. One patient has had twelve attacks, and each time his loss amounted to from four to five pounds. The maximum loss in this category of cases was nine pounds after two attacks during the same day. 4. During the status epilepticus the loss was not great, one to one and a half pounds. But the total loss in some cases extended to twenty-five per cent. of the weight of the patient. 5. Among the cases of epilepsy complicated with mania, those that suffered from convulsions and vertigo were particularly observed. In one such case, in the course of observation, the weight fell from 146 to 114 pounds.

Although the cause of this phenomena lies in the increased nutritive changes, still, to determine the exact nature of them, a further study of the question is needed.—*Vratch*, 1880, No. 2.

The Condition of Blood in the Course of Diseases Affecting Lymphatic Glands.—Dr. Pawloff read a paper on this subject before the same convention. His conclusions, based upon ninety-three examinations of fifty-two cases of different diseases of lymphatic glands, from simple hyperplasia to profuse suppuration, are as follows: the number of red blood-corpuscles is not affected. Increase of white corpuscles is observed only in the course of purulent processes in the connective tissue surrounding the gland. The decrease of hæmoglobin is due, not to the glandular lesion, but to the state of patient's general habit.—*Vratch*, 1880, No. 4.

Arterial Transfusion of Blood.—Prof. S. P. Kolomnin performed this operation ten times. He injected defibrinated blood into the peripheral end of the radial artery. He claims the following advantages over the venous transfusion: it is as simple and as easily performed as the latter, a greater amount of blood can be injected (from 100 to 220 c.c.), which enters the heart more gradually, and there is no danger of obstructing the vessels of internal organs.—*Transactions of the Society of Russian Physicians*, 1879–1880.

Curious Cases of Volitional Control over Involuntary Acts.—Dr. Berliakoff reports in *Vratch*, 1880, No. 8, a case of a man suffering from syphilitic ulceration of the rectum, who succeeded in gaining such control over his sphincters, that he could, under certain conditions, open the anal orifice, permitting a perfect inspection of the rectal mucous membrane to the depth of seven centimetres, the anus appearing as a hole two centimetres in diameter. He could retain the parts in this condition for ten to fifteen minutes, becoming very much fatigued at the end. To accomplish it, he had to place himself in the position known as *à la vache*, cover his head with a blanket or a gown, stop breathing and draw in the abdomen: perfect silence was absolutely necessary. He could not give any explanation of how he was doing this. Silence and darkness were necessary to permit him to concentrate his mind on the act. He was led to this by a desire to assist his physician, as local manipulations were very difficult and painful. Prof. Manassein, editor of *Vratch*, speaks of two medical students: one of whom can accelerate and the other retard the pulse-rate at will.—*Ib.*

Faradization of Abdominal Muscles for Ascites.—Dr. Sigrist reports a second case of ascites successfully treated in this manner. Ascites was due to hypertrophic cirrhosis of liver. Every muscle was made to contract from fifteen to twenty-five times; two seances per day. Under this treatment patient began to lose in weight about 200 grms. per diem; amount of urine became double, and abdominal circumference was diminishing from one-half to one centimetre per day. On the tenth day abdominal bandage was applied. In three weeks ascites entirely disappeared and had not recurred when seen three months later.

A similar case, complicated with nephritic congestion, diminished urinary secretion, and trace of albumen in the urine, was treated by faradization alone, by Dr. Popoff (*Vratch*, 1880, No. 22), with the like result. Amount of urine was increased from 800 to 1,000 c.c. to more than double the quantity. Albumen disappeared from the urine on the eighth day and did not return. Abdominal circumference fell from ninety-five centimetres to eighty centimetres; ascites was cured; spleen became much smaller. The days when faradization was omitted, amount of urine was always smaller. Beneficial effects of this treatment was also ascertained in the clinique of Dr. Lesch.—*Vratch*, No. 9, 1880.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, November 6, 1880.

THE VALUE OF SANITATION IN NEW YORK.

A REVIEW of the vital statistics of this city for the present year may on some accounts produce a little discouragement as regards the efficacy of sanitation. We have had for some years as efficient a board of health as exists in any city, and its work is helped by a reasonably good supply of money. In addition to this, there are several private associations which contribute largely to the work of preventing or relieving sickness among children. Our tenement-houses are visited by sanitary inspectors and physicians; many of the children of the poor have been taken out upon the harbor, or have been to sea-side sanitaria, or carried for the summer into the country; and there has been, apparently, every possible attempt made to lessen the prevalence of disease. Nature has to some extent made this work easier, for New York is admirably situated for purposes of thorough drainage, and it can be swept by the wind from every quarter.

On looking over the tables of vital statistics, however, we find that, in the present year, sickness, and especially contagious disease, has markedly increased, and that for a few weeks in the past summer New York had the highest mortality rate of any city in the world which reported its deaths. This rate, for example, during the week ending July 3, 1880, was 56.20 per thousand, estimating the population at 1,200,000. For several weeks an extremely high rate was kept up, despite every precaution.

This particularly high death-rate cannot be ascribed to the heat alone, because there are many hotter cities than New York; and in these—such, for example, as Philadelphia and St. Louis—the mortality was much lower than it was here. Neither can it be entirely ascribed to the condition of our tenement-houses, for the increase of mortality was not proportionately so very much greater in the tenement-houses than in other districts. We must add, probably, to these factors, an "epidemic constitution" and —dirty streets.

By examining the statistics of contagious diseases for the year 1880 as compared with 1879, it will be found that during the present year there has been an increase in nearly all forms. The exact figures we have already published. This increase has not been very great in any particular case, but, taking it as a whole, the difference is very marked. And this difference, as we remarked, has occurred in the face of active measures to secure purer air, better drainage, and disinfection and isolation in all cases of infectious disease. But these facts do not give a brilliant showing for the efficacy of sanitation, though we do not mention them with the intention of undermining faith in hygiene or boards of health. It has been abundantly proven that our City Board has considerably reduced the mortality rate during the years in which it has been in existence, and the number of lives thus saved or prolonged amounts to many thousands.

On the other hand, it does not do to ignore the darker side of the matter. Sickness will prevail and death-rates increase, although sanitary officials do all in their power to prevent them. There is no danger that the people will fail to know it when the authorities are making the city healthier. But it is quite as important, though not nearly so likely, that the people should know when the city's health is not so good. A daily contemporary chooses to ascribe all the sanitary and other ills of our municipality to the dominant party which looks first after the "spoils" and last after the streets. That the present rule under which New Yorkers live, is deplorably bad in many respects, we can safely assert without being accused of partizanship. But, apart from its politics, there are two peculiarities in our city to which its unhealthiness is largely due—two things which are to a great extent under municipal control: these are the dense accumulation of people in badly constructed tenement-houses, and the filthiness of the streets. A great deal can be done to relieve the first trouble; vastly more improvement, however, can be accomplished in keeping our streets clean. They are now the reproach of the city; and it cannot be that the miles of festering filth exposed to the summer sun has not something to do with the mortality rates.

These are lessons, then, in the vital statistics of the year. Health boards do not always succeed in the fight against pestilence, or even against the ordinary course of disease. And when this is the case in New York, we may look for explanation not only to the obstinacy of pathological processes, but to the peculiarities of municipal politics.

CIVIC MALARIA.

This is a term used—perhaps coined—by Dr. John C. Peters in the annual report of the Committee on Hygiene of the Medical Society of the County of New York. We presume that he used the word "malaria" in its broadest sense, viz., "*bad air*," and merely applied a slightly mysterious and high-sounding phrase to the collective bad air of great cities and its varied ingredients. As far as we understand Dr. Peters, he merely claims that certain parts of New York, like Harlem, and many large cities, were once truly malarious in its narrow sense, and produced intermittent, remittent, and other paludal fevers and do so still; thus Murray Hill was once a hotbed of fever and ague; malarious diseases in large numbers have been produced by the deep upturning of the soil in excavating the Fourth Avenue Tunnel, and also along the lines of the elevated roads. But the subsoil of large cities is always further contaminated by bad drainage, obstructed underground watercourses, filling of low-lying places with street-sweepings and other more objectionable refuse; leakage from numberless old-fashioned out-door privies and cesspools, from sewers and gas-pipes, and last but not least, soakage from perennially filthy streets and gutters. The exhalations from such a subsoil when liberated produce a peculiar typho-malarial fever, as was evidenced when large water-pipes were put down in one of our largest and most fashionable avenues. Dr. Peters claims that ordinary street pavements, especially when made of cobble-stones, are not sure preventives of the rise of these miasmatic or malarious exhalations from the subsoil; much less are many of the ordinary pavements of the cellars of numerous houses, which are far from being air or water-tight, and allow subsoil bad air to rise, which becomes especially noxious at night when all the doors and windows are closed. The exhalations from the street-sewer openings, and of these into the docks, and from the water-logged soil in the neighborhood of wharves, are highly productive of all the varieties of malarial and typho-malarial and miasmatic diseases. Bartholow includes cholera, diphtheria, cerebro-spinal meningitis, influenza, etc., among the miasmatic diseases, while the Germans have correctly added a class of miasmatic infectious and miasmatic contagious disorders. The miasmatic contagious diseases are such as are developed exterior to the body in animal and vegetable decompositions, to which has been added the specific poison of some disease which had its origin in a diseased body. The peculiarly miasmatic contagious diseases are typhoid and yellow fevers, diphtheria, influenza, and Asiatic cholera. The miasmatic infectious disorders are cholera infantum, cerebro-spinal fever, lung fever, etc., etc.

Additional causes of civic malaria, according to Dr. Peters, are exhalations from gas-works, offal-rendering, the making of fertilizers, from various other offensive and noxious trades which produce smoke and smells, and from the dumping-grounds of stable-manure and street-sweepings and garbage. These abound along the river banks of many large cities, and in one of them, not far distant from New York, the principal slaughtering establishments are sandwiched between docks for manure-dumps and street-sweepings on the one side, and some of the most offensive offal-rendering establishments on the other, and the meats are cooled off in this impure air.

According to Dr. Peters, cholera infantum or summer complaint is a miasmatic infection arising from the foul air of cities, aided by heat, bad milk and food. Impure air is the great cause, and pure air the great cure. Diphtheria is a miasmatic contagious disease, arising from impure air, and sometimes becoming contagious. True influenza—not mere common catarrh—is a miasmatic contagious disease, arising originally from impure air, and becoming contagious like diphtheria and measles. Typhoid fever is a filth fever, which becomes infectious first, and contagious afterward by the decomposition of the discharges. Asiatic cholera and yellow fever are miasmatic disorders which become infectious and contagious like typhoid fever.

We give Dr. Peters' views for what they are worth, and can only say if the streets, gutters, sewers, and subsoil beneath us were as pure as the great mass of air above us, there would be as little filth, malarial, typho malarial, and miasmatic contagious diseases in large cities as in the purest country places.

THE QUESTION OF ETHICS IN THE MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Another annual report to the Medical Society of the County of New York, that presented by Dr. Samuel Sexton, the Chairman of the Committee on Ethics, invites a word or two of special comment. Although the printed minutes of the society will soon place this report, which touches upon many points of unusual interest to the profession, befo e its members, we may in the meantime briefly allude here to some features of the committee's work. From the observations of the committee the most amicable personal relations are maintained by the profession, a state of affairs that we should naturally expect to prevail in a great metropolis where rivalry seems to inspire greater endeavors rather than petty jealousies; but on the other hand rivalry seems also to have engendered among professional men a desire for advancing their interests by methods that, although not affecting personal relations directly, are held by the codes of ethics, both national and state, to be inimical to the general interests of the profession. We here allude to professional advertising, a subject upon which the County Society has expressed its sentiments in the plainest terms. On this subject there is among physicians a difference of opinion, and it seems to have been the endeavor of the committee to deal with it on broad grounds, without giving offence to any by singling out individual cases for special investigation. That they were not able in all cases to avoid criticism was to be expected, for there were some who failed to appreciate the delicate position of the gentlemen who accepted this disagreeable duty with a desire to aid the society in keeping the flock within the fold. Every means suggested by the codes was resorted to in the endeavor to prevent members of the society giving certificates to dealers in mineral waters, proprietary goods, etc., and it is to be regretted that its efforts were only partially successful, for it is believed that such advantages extended by the profession to trade interests is an injury to our own. We should state here, that before its adjournment, the annual meeting, at which there was a large attendance, adopted a by-law which it is hoped will effectually prevent members publishing such certificates in the future.

As regards the publication in the newspapers of interviews with physicians on medical subjects, responsibility in such cases is not avoided, the committee believes, by placing the advertising physician's name at the beginning of an article instead of the end; it was found, however, that existing laws did not reach these cases, although they may have been sufficient for the evils that existed when they were enacted. We agree with the committee that it is time that the codes of ethics should be revised in order to free them of the accumulated mass of verbiage, sentimental advice, and useless moral platitudes with which they are encumbered; such laws as we find buried here by no means serve the purposes of the profession of the present day. It really seems as though the society ought to either make ample provisions for holding its members to a more strict accountability, or else cease altogether the futile efforts that when persisted in bring ridicule upon its actions. Perhaps, after all, we shall, as the committee intimates, have to rely upon the higher sentiment in the profession and simply hold ourselves amenable to the unwritten code that prevails among gentlemen everywhere. This report refers to some points in the system of ethics of the Medical Society of the State of New York, that seem to have long been observed in the breach only; one is as follows: Every practising physician, under these laws, forfeits his license by a failure to join a county medical society. The other alludes to the termination of membership, which may occur by abandoning the profession, by removal from the county, by expulsion, or by death. It now remains with the State Society to carry forward the work that these gentlemen have inaugurated in so earnest a manner, by providing effective measures for meeting these questions. There are other recommendations in the report which should command the careful attention of every member of the society. Of the committee itself, it may be said that it fully accomplished its object in clearly bringing forward to the profession the numerous questions of general interest that were referred to it for action.

A STATE BOARD OF HEALTH FOR VERMONT.

A BILL has been introduced into the Vermont legislature, now in session, to create a state board of health. It provides for the appointment of six persons, who, with a secretary, shall constitute the board. They are to meet regularly once in two years, and oftener if necessary. Their duties include the supervision of all matters pertaining to public hygiene. The mayor and aldermen of the cities, and the selectmen of the towns, are made *ex officio* local health officers, whose duties are to keep things in good sanitary condition. The State Board is chiefly advisory, but the local boards have executive power. The secretary of the State Board is to deliver one lecture on sanitary science annually, in every county in the state.

The bill seems to be a good one, but it appropriates only the ridiculous sum of $500 for annual expenses. There are generally a great many doctors in the Vermont legislature, and they ought to see that the bill, if passed, is not made inoperative by a short-sighted parsimony.

Reviews and Notices of Books.

CLINICAL URINARY EXAMINATIONS. Arranged and compiled by J. F. GOULD, M.D. Boston: Doane & Greenough. 1880.

THIS is a blank case record prefaced by half a dozen pages on the clinical examination of urine. A table is given showing the action of the main reagents in the examination of urine; also tables with the indications given by the urine regarding general and renal diseases.

The division of the nephrites into seven different kinds is an impracticable clinical refinement, even if justifiable pathologically. Otherwise the tables are clear and helpful. The book is dedicated to the physician who is clinically earnest and honest, and is not afraid of a little extra work. It is to be hoped that on this, if not on many other accounts, the manual will be a success.

THE BRAIN AS AN ORGAN OF MIND. BY CHARLES BASTIAN, M.A., M.D., F.R.S. Pp. 708. New York: D. Appleton & Co. 1880.

THIS book is remarkable for the lucid manner in which a difficult subject has been treated. Although, as the title implies, the work treats of a philosophical subject, the style is so fluent and simple that it reads as smoothly as an essay on some popular historical subject. The author, an avowed evolutionist of the most advanced type, has taken the evolution theory as a basis upon which all his views are founded. While we recognize the fact that the large majority of scientists of the present day adopt the theory in question, we believe that, in the present instance, the author has at times accepted certain views as proven, because they harmonized well with the general theory, although they are not by any means thoroughly demonstrated.

In the first nine chapters Bastian describes the uses and origin of a nervous system and its anatomy in the lower animals. These chapters will well repay perusal by all as a preparation for the study of the anatomy of the nervous system in man.

Chapter X. contains a discussion on the scope of mind, and it is very evident from the following extract that the author's views on this subject are decidedly different from those generally entertained.

"In treating of 'the brain as an organ of mind,' therefore, it will be understood that we use the word 'organ' merely in the sense that it is a part whose molecular changes and activities constitute the essential correlatives of those phases of consciousness known as sensations, emotions, thoughts, and volitions, *as well as of a considerable part of the sum total of those other related nerve-actions which are unattended by consciousness, and whose results form, in accordance with the views above stated, so large a proportion of the phenomena comprehended under the general abstract word 'mind'*" (italics by the reviewer). Or, as he expresses it in another place, "the word 'mind' must be very considerably enlarged, so as to enable us to comprise, under its new and more ample signification, the results of all nerve-actions other than those of outgoing currents."

Unless we arbitrarily define the boundaries of mind as coextensive with those of consciousness, and thus exclude what is now known as unconscious cerebration, we are of the opinion that the position assumed by our author is well taken, and that the definition given above is a logical outcome of his previous statements.

Then follow chapters upon reflex action and unconscious cognition, instinct, nascent reason, emotion, imagination, and volition, the mental capacities and powers of higher brutes, will, and voluntary movements, cerebral mental substrata, the cerebral relations of speech and thought, etc., all of which are discussed in an eminently suggestive manner, so that even though we cannot always entirely agree with the views expressed, we are, nevertheless, deeply impressed by the judicial fairness of the author and by the depth of his philosophical acumen—the latter, we are sorry to say, not being a universal characteristic of the medical men who have ventured to enter the field of psychology.

It is interesting to note that Bastian takes strong ground against Fenier's view with regard to the motor centres of the cerebral convolutions, and which has also been forcibly urged by the entire body of English physiologists and pathologists. His views are best expressed in his own words: "The cerebral cortex is, in our view, to be regarded as a continuous aggregation of interlaced 'centres,' toward which ingoing impressions of all kinds converge from various parts of the body; here they come into relation with one another in various ways, and conjointly give rise to nerve-actions, which have for their subjective correlatives all the sensations and perceptions, all the intellectual, and all the emotional processes which the individual is capable of experiencing. From these terminal and complexly related 'end-stations' for ingoing currents, and from certain annexes in connection therewith, outgoing currents issue, which rouse in definite ways the activity of the highest 'motor centres' (the corpora striata and cerebellum), and through them evoke the properly adjusted activity of lower motor combinations, so as to give rise to any movements that are 'desired,' or which are accustomed to appear in response to particular sensations or ideas."

But a thorough review of even a single chapter would require several pages, and we must therefore content ourselves by urging a careful study of this book upon all who manifest any interest in the subject.

As a preliminary to the study of the intimate structure of the brain, its perusal will be of great service, giving, as it does, a very fair and concise summary of most of our present positive knowledge of the topic, and in a style which is much easier of comprehension than that of systematic treatises on cerebral anatomy.

A New Case Record, General and Gynecological, for Chronic and Acute Cases, and a Complete Obstetric Record. Copyrighted by Joel A. Miner, Ann Arbor, Mich. 1880.

This case-book will no doubt be very acceptable to some practitioners, and will serve a good purpose in securing systematic records that can be easily referred to. Its method of arrangement is somewhat complicated, and some study will be required before the book can be easily used.

American Health Primers. The Skin in Health and Disease. By L. Duncan Bulkley, M.D. Philadelphia: Presley Blakiston. 1880.

This little work on the skin is one of the most complete and carefully written of the Primer Series. The author states that he has endeavored to make the book serve both as a guide for the preservation of the health of the skin and as a popular dictionary or encyclopædia in matters pertaining to dermatology. In this object he has well succeeded, and the book will have a more permanent value than most of its class. It is fully illustrated, and with excellent cuts.

Jahresberichte über die Fortschritte der Anatomie und Physiologie. Herausgegeben von Dr. Fr. Hofmann, Professor an der Universität Leipzig, und Dr. G. Schwalbe, Professor an der Universität Jena. Leipzig: F. C. W. Vogel. 1880.

Annual Reports on the Progress of Anatomy and Physiology. Edited by Drs. Hofmann and Schwalbe.

In conjunction with some of Germany's most distinguished *savants*, Profs. Hoffmann and Schwalbe publish annually these thorough and complete reports on the progress of anatomy, embryology, and physiology. Sections I. and II. of Volume VIII. are before us, fully maintaining the standard of excellence which characterized the previous volumes. The aim of the authors is not so much to present a critical analysis of recent work in the fields of these fundamental medical sciences, as to furnish an abstract and summary of what has been accomplished in them. Of course, impartial criticism is not altogether abstained from; but the bulk of the volumes is made up of condensed information regarding the progress of anatomy and physiology. Accordingly these books will be of inestimable value to all who are interested in those branches, and who, wishing to be kept *au fait* of these sciences, are unable to gain access to all the recent literature of the subjects. Merely to glance one's eye over the index will impress one with some notion concerning the vast amount of intellect and labor continually busy with the comparatively unremunerative pursuit of scientific knowledge for its own sake These reports are strictly international, no one country being neglected at the expense of another. For this very reason it is somewhat humiliating to our national pride to find so very meagre a representation in the pages of these books, while our English brethren make a very fair showing, and Germany fairly excels in elaborate monographs and exhaustive treatises, some apparently on the most insignificant of subjects. It is impossible to do more than thus indicate in general terms the character of the books before us, for any attempt to enter into the details of analysis would clearly exceed the limits of our space. It is not too much to say that these reports form indispensable works of reference to all who, engaged in anatomical and physiological pursuits, wish to keep pace with modern progress in these important branches of medical science.

Traité d'Anesthésie Chirurgicale, contenant la Description et les Applications de la Méthode Anesthésique de M. Paul Bert, par le Docteur I. B. Rottenstein, Membre de l'Académie Leopoldina Caroline, de la Société Odontologique de New York, etc. Avec 41 figures intercalées dans le texte. 8vo, pp. 428. Paris: Germer, Baillière et Cie. 1880.

A Treatise on Surgical Anæsthesia, with the Description and Mode of Application of the Anæsthetic Method of Paul Bert. By Dr. I. B. Rottenstein.

Anæsthesia for surgical purposes, ever since its discovery, has received a goodly share of attention, both professional and unprofessional. Even at the present day, when all are agreed as to the great utility of anæsthesia, the particular anæsthetic method to be chosen is still a point of much heated controversy, and will probably remain so until we shall have found a perfectly reliable and absolutely innocuous drug.

Dr. Rottenstein is apparently a dentist. Now, although this would not preclude the possibility of his giving us an excellent work, it certainly explains why his book is not so much a general and impartial treatise on surgical anæsthesia as a strong plea in behalf of a more extended employment of nitrous oxide gas administered according to Bert's method. A general treatise on surgical anæsthesia, finished, if not entirely written, in 1880, should, under the heading of rarely employed anæsthetics, certainly contain more than seven lines on the subject of bromide of ethyl. Mention might also have been made of the method of inducing partial anæsthesia by rapid breathing, and of the possibility of performing minor operations during the period of primary narcosis. Despite, however, these and other defects, Dr. Rottenstein has produced a creditable volume, which, even if it lacks originality, presents at some length and with laudable thoroughness most of our present knowledge on the subjects of which it treats. We will briefly indicate the contents of the twenty-five chapters composing the book. Chapter I. is historical, and in it the author urges the claims of Horace Wells to the title of discoverer of anæsthesia. Incidentally we may here remark that the work is adorned with a good steel engraving of that gentleman. In the second chapter the progress of anæsthesia is discussed, with nitrous oxide first in the list of anæsthetics. The following chapter is devoted to chemical "notions," nitrous oxide again coming first with ten pages, and being followed by the remaining agents with all in all nine pages. The general action of anæsthetics has a chapter by itself, and then we are treated to fifty-eight pages on the physiological action of laughing-gas, also in a separate chapter. The modes of administering anæsthetics, the accidents attending and following their use, the treatment of those accidents, and the indications and counter-indications of surgical anæsthesia, are disposed of in four chapters. The following six chapters treat of the various applications of anæsthesia in surgery, ophthalmology, and dentistry. Chapter XVI. deals with the medico-legal aspects of the subject. Anæsthesia produced by the combined action of morphine and chloroform is the subject of the following chapter, in which, by the way, we were somewhat startled to find Nussbaum, of Munich, suddenly Gallicised into Nüsbaum. Dr. Rottenstein is so evidently a Teuton, besides being the author of a German book, that there appears to be no excuse for this barbarism. Local anæsthesia is described next, and then follows the chapter giving the details of Bert's method. This gentleman's theory concerning the production of anæsthesia by the respiration under pressure of a mixture of nitrous oxide with oxygen gas has been verified by experimentation upon animals and by clinical trials on man. Theoretically, therefore, we find no fault with the method, although it must be admitted that the number of experiments is not so great as to warrant a general conclusion as to its entire and invariable immunity from danger. But at present the method must be confronted with great practical objections to its universal employment. We will mention only the formidable apparatus apparently necessary for the production of anæsthesia by this method, and the great cost of such apparatus. The author's own figures are "scarcely" $5,000 for a large receptacle able to accomodate 300 spectators, or $3,000 for a complete apparatus for 40 persons.

The remaining chapters deal with the "uses of anæsthetics in obstetrical practice," "rarely employed anæsthetics," and the comparative value of the various anæsthetic agents. The work closes with general conclusions, clinical observations, and a bibliographical index.

A Treatise on Comparative Embryology, by Francis M. Balfour, M.A., F.R.S. In two volumes. Vol. I. London: Macmillan & Co. 1880. 8vo, pp. 514.

The reputation which Professor Balfour has gained as an embryologist insures authority to the present work. It is indeed the most exhaustive treatise that has yet been written upon the subject in question. It in fact fills an almost entirely unoccupied field, since, with the exception of a small work by Packard, and the previous writings of Balfour himself, nothing but detached monographs have been written upon comparative embryology. The book, therefore, will be a necessity to all students in this department of science. The different chapters are profusely illustrated, and the typographical character of the book is excellent.

If there had been some facts in regard to comparative anatomy added to the work it would be more widely appreciated; but this does not of course alter the fact that it now stands as the authority on the subject of which it treats.

Transactions of the American Dermatological Association, with the President's Address. Third Annual Meeting, New York, 1879.

The American Dermatological Association, whose transactions are here given, is one of the most creditable of the medical organizations in this country. Though now only in its third year, it has already done work which has gained notice and high praise, both abroad and at home. The rise of dermatology and the history of the present society are fully and fittingly told in the very able address of Dr. Duhring. The activity of the members of the Association is shown by a list of their contributions to dermatology in the year 1878, a list covering over three pages. The papers in the present volume, though not numerous, are for the most part of much value practically, and have a thoroughly scientific character as well. We make no analysis of them now, because they were quite fully reported in the Record on their first appearance.

President's Address at the Maine Medical Association, June 15, 1880, by Seth C. Gordon, M.D.

We find in this short address an able plea for better medical legislation in Maine. The present laws are pernicious and absurd; and it is to be hoped that the demands for reform will be listened to.

Tunnel Trichinosis and the Cornwall Outbreak.

We have received from Dr. Cobbold a pamphlet containing some facts relative to the endemic disease which appeared among the laborers in the Mt. St. Gothard tunnel, also concerning the outbreak of fever on board the English school-ship Cornwall. Regarding the first matter, the observations of Dr. E. Perroncito are quoted, showing that the symptoms of oligæmia perniciosa, developed among the tunnel workmen, were due to the presence of two different kinds of parasites in the intestinal canal. These parasites were: *anchilostoma anguilula* and *anguilula stercoralis*. They produced identical symptoms, which are classed under the head of anchylostomosis.

Referring to the fact that several authorities had mistaken this anchylostomosis for trichinosis, Dr. Cobbold cites a like error committed by the *Lancet* regarding the Cornwall fever. In an article entitled "Trichinosis and Trichinosis" the *Lancet* asserted that the Cornwall fever was a trichinosis, when in fact no trichinæ were found at all, nor did the symptoms correspond with those of trichinosis. Dr. Cobbold states that much ignorance prevails regarding many of these parasites and the symptoms they produce.

◆

The Physiology of Walking.—M. Marey, by means of an ingenious instrument, called the "odograph," has discovered some interesting facts in regard to walking. It was ascertained that the step is longer in going up-hill than in going down-hill. It is shorter when a burden is carried; longer with low- than with high-heeled boots; longer when the sole is thick and prolonged a little beyond the foot than when it is short and flexible. It appears that the heel may be advantageously removed almost entirely; but it is disadvantageous to prolong the sole beyond a certain limit, or to give it more than a certain amount of stiffness. On level ground the step becomes longer in proportion to its frequency. In going up-hill the steps are longer but less frequent.

Reports of Societies.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, October 21, 1880.

Fordyce Barker, M.D., LL.D., President, in the Chair.

The Statistical Secretary, Dr. Francis V. White, announced the death of Drs. Chas. M. Allin and J. Ellis Blake, with brief biographical sketches.

The President paid a worthy tribute to the memory of both deceased Fellows.

Dr. Goddard, of Ohio, and Dr. McDonald, of Ontario, Canada, were introduced to the Academy, and invited to seats upon the platform.

"SOME UNSETTLED QUESTIONS IN REGARD TO NASAL CATARRH"

was the title of a paper then read by Dr. F. H. Bosworth. (See page 505.)

The discussion was opened by Dr. J. H. Douglas, who took issue with the author of the paper on certain points concerning etiology and treatment. He regarded catarrh as a constitutional and not a local disease. What was ordinarily called cold in the head manifested itself first through constitutional symptoms, such as chill, fever, etc., and the symptoms of what was called catarrh came subsequently. Stenosis and hypertrophy referable to the nasal passages came subsequently to constitutional symptoms. Chronic nasal catarrh he regarded as the simple result of frequently repeated attacks of acute catarrh. In chronic nasal catarrh other parts of the body were invaded, as a rule, and his custom was always to examine the urine, and he usually found a deficiency of the salts that were physiologically eliminated by the kidneys. He also found the liver involved in most cases. His own experience had been that chronic nasal catarrh could not be cured by local means alone; but that by a combined local and constitutional treatment it could be cured.

The hypertrophy, the swollen condition, which was one of the first symptoms of nasal catarrh, could be easily relieved by reducing the sensitiveness of the mucous membrane; and his uniform plan of treatment was first to cleanse the surface of the membrane with the douche, and then make a local application of some of the preparations of opium—laudanum being that which he usually employed, from one-half to full strength. The local symptoms being relieved, he then turned his attention to the existing constitutional disturbance.

In chronic nasal catarrh, where there had been long-continued irritation of the mucous membrane, resulting in atrophy of the glands, etc., he invariably resorted to the local application of such agents as would stimulate the parts. First thoroughly cleanse the mucous membrane by means of the nasal douche, anteriorly and posteriorly, and then stimulate the tissue with heat, and afterward apply some bland agent, such as vaseline, etc. In that way there was no destruction of tissue, and the glands which were necessary to supply, properly, mucus for lubricating and protecting these parts were preserved. Again, he addressed himself to the existing constitutional disturbance with even more care than in the acute cases. He regarded the liver as a very frequent source of evil, and if defective in its action, the salts which normally should be eliminated by it must find exit through some other channel. If such morbid material did not find its exit through the kidneys, the skin, or the lungs, it was very apt to manifest its evil effects in the mucous membrane of the nasal passages. An ordinary cold in the head might be the starting-point of all that. Several of his patients had had a severe attack of jaundice with their nasal catarrh, and when they had recovered from the former, the latter was entirely relieved.

Dr. Andrew H. Smith paid special compliment to the candor of the author of the paper in mentioning the recognized and inherent difficulties in the satisfactory treatment of nasal catarrh. He thought that the more a man knew concerning nasal catarrh the less confidence he would have in his ability to treat all cases satisfactorily. Not that he believed treatment to be inoperative, for he was fully convinced that even every bad case could be materially relieved, yet he as firmly believed that certain cases could not be radically cured. The difficulties with reference to effecting a cure were numerous, and arose from various sources; but probably the first in importance was the fact that, in a majority of cases, the original cause remained operative, and from the nature of the case could not be removed. The cause might exist in some hereditary peculiarity of the patient, or some acquired diathesis, or in occupation, or peculiar atmospheric influence, and it might not be possible to change those conditions. With reference to local treatment he doubted that *spray* reached all portions of the mucous membrane of the nasal passages—that is, reached them so as to be thoroughly satisfactory. Particles of the liquid might adhere to the surface in places, but it was exceedingly difficult to cause those particles to take a deflected course. The first surface, by which they were struck, arrested the greater portion of them, so that those prominences received the greater share, while those which were situated, as it were, around the corner, escaped with almost no application whatever. He thought that the same difficulty was somewhat diminished by using powders; for the moist surfaces first touched were rendered dry, and therefore the currents and the eddies could carry the dust onward so that the surface beyond could be pretty thoroughly covered with the pulverized agent. With reference to the nasal douche, he thought that it could be used very efficiently posteriorly, and that if the stream was projected with some force the water would not observe its own level, but would reach nearly all portions of the cavity with some degree of certainty; with the exception, perhaps, of those cases in which the disease extends into sinuses connected with the nose. With reference to caustics he had of late used chromic acid, with water only sufficient to liquefy the crystals. It was sufficiently powerful to destroy at once the sensitive nerves with which it came in contact. A great objection to acetic acid was the intense pain that it produced. He had used nitrate of silver in powder a great deal and with very satisfactory results. An impalpable powder could be made by triturating sulphate of potash, ʒ j., subnitrate of bismuth, ℥ j., and nitrate of silver from 10 to 40 grains, according to the strength desired. That powder, which did not become lumpy by exposure, could be readily blown into the nasal passages without difficulty. The advantage was that this powder remained in contact with the surface of the mucous membrane for a long time, and the action, though it might be mild, was very persistent. He had obtained better results with that agent than with any which he had ever employed.

One great obstacle to effecting a radical cure was that when improvement had reached a certain point, where relief from the disease would be less than the inconvenience resulting from treatment, the patient disappeared with a remnant of the disease almost always left behind. The vast majority of people, when they ceased to be actively disturbed by the disease, ceased treatment. Again, the most healthy mucous membrane, when subjected to constant contact of foreign substances, would finally be brought into an abnormal condition, and he doubted whether they could be applied daily without themselves producing such results, especially the more powerful agents. So even if we possessed a specific local application for nasal catarrh, a time would come when the continuance of such local application would be deleterious. He fully agreed with Dr. Douglas that there was a constitutional element present in most cases of nasal catarrh. The little instrument to which Dr. Bosworth referred should be made of hard rubber instead of glass.

Dr. Asch remarked that he agreed entirely with Dr. Bosworth in his description, and essentially in the treatment of the disease so far as related to the hypertrophied mucous membrane and the enlargement of the turbinated bones. But it seemed to him that, in a great many cases the catarrh did not arise from that cause, for many cases occurred in which there was no hypertrophy nor enlargement of the turbinated bones. He believed that in such cases the lesion existed upon the posterior surface of the velum, and could be easily recognized with the rhinoscope. He also thought that, in many cases, the cause was constitutional. In all cases of chronic nasal catarrh he had obtained better results by directing attention to the constitutional as well as the local treatment than by resorting to the latter only. The principal causes and symptoms were constitutional, the local ones were accessory. He made use of Dobell's solution purely as a cleansing agent. Local applications were entirely useless so long as the mucous membrane was covered by secretion. He employed nitrate of silver, twenty to forty grains to the ounce, and had been able to control most cases of nasal catarrh that were not specially bad ones. He made his local application to the posterior surface of the velum either with a brush or a platinum probe wrapped with a pledget of cotton, and by the aid of the rhinoscope. For removing redundant tissue, when necessary, he thought the galvano-cautery was the best means that could be employed.

Dr. H. Knapp spoke of the analogy existing between certain diseases of the nasal passages, the pharynx, and the ear, and certain diseases of the eye. The two diseases of the eye which were repeated in the other passages were *trachoma* and *blenorrhœa*. At one time those affections were treated by burning away the tissues, etc., but that plan had been abandoned entirely. The vegetations, it was true, disappeared under the old plan, but the mucous membrane also; and since it was essential to have a mucous membrane for the purpose of keeping the eye smooth, such remedies were now applied as only stimulated and favored an excess of blood in the tissues, and thus caused absorption. Long-standing trachoma could be successfully treated in that way. In nasal catarrh there certainly was hypertrophy of the mucous membrane, adenoid granulation, which frequently enough had been crushed or cauterized; but, he had commonly abstained from that method, and, by resorting to mild local applications daily, for a long time, had obtained finally much more satisfactory results than when more severe measures had been adopted. He was certain that he had, by means of the posterior nasal syringe and the local use of mild agents, persisted in regularly for months, effected a perfect cure, especially in children.

With regard to the origin of the affection, there was also an analogy between it and diseases of the eye and ear. Formerly, oculists held that trachoma was a constitutional disease, but latterly it had come to be regarded as a local affection.

Dr. A. J. Chadsey regarded the cause of nasal catarrh as an obstruction of the capillaries, hence retention of effete material; and the agents most serviceable in removing that obstruction were diaphoresis and mercury. No local remedy could remove it. He also spoke of the beneficial effects produced by change of climate.

Dr. O'Sullivan spoke of the eminently satisfactory results obtained by the late Dr. Horace Green, in the use of the nitrate of silver in this particular affection, and his statements were corroborated by Dr. Douglas.

Dr. Bosworth, in closing the discussion, remarked that, while very much good could be done by the use of the spray, the douche, powders, the syringe, etc., it seemed to him the treatment of nasal catarrh should be placed upon a somewhat better basis than that. The treatment he had described could be resorted to without serious discomfort to the patient. Certainly, he had sought diligently for a diathesis which might be regarded as the underlying cause of the disease, but had failed to find it. In the majority of cases there were no constitutional symptoms. It existed in people who were otherwise perfectly well. With regard to change in climate, it was beneficial as a rule, but as soon as the patient returned the atmosphere of the old locality would again irritate the hypertrophied parts, they would respond to all kinds of irritation, and the catarrh would return.

The Academy than adjourned.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Annual Meeting, October 25, 1880.

Dr. A. E. M. Purdy, President, in the Chair.

After the reading of the minutes of the last stated meeting the report of the Comitia Minora, together with the minutes of that committee during the last year, were read.

The Treasurer and the Auditing Committee then presented their reports, after which the Society proceeded with the balloting for officers, with Drs. Conrad, Mittendorf, and S. S. Jones as tellers.

While the ballots were being counted, the Committee on Ethics, through its chairman, Dr. Samuel Sexton, presented an elaborate report which dealt candidly with the many vexed ethical questions and intricacies that had been brought before them during the last year.

On motion, the report was accepted and ordered upon the minutes, with instructions that it should be printed and distributed before the adjourned annual meeting.

The Committee on Hygiene then made its report, through Dr. J. C. Peters, Chairman, and Dr. E. G. Janeway. Dr. Peters spoke in unmistakable terms of the condition of the streets of the city, the deleterious effects produced by sewer-gas, offensive smoke, stables, offal nuisances, etc. The latter had been referred to the Health Department as a complaint. Mention was made of the improved but still imperfect condition of the Fourth Avenue tunnel, to the nuisances belonging to the elevated railway, and to the filthy and overcrowded condition of street railway cars.

The Chairman also presented a report offered by Dr. Chas. C. Lee, who directed attention to the filthy condition—sufficiently filthy to constitute a nuisance—of that portion of the city lying between Sixty-seventh and Sixty-eighth Streets and Third and Lexington Avenues. It was believed to be the duty of the mayor and the controller to see that the nuisance was abated.

The report of the committee was continued by Dr. Janeway, who made special reference to the mortality in the city from small-pox, typhoid fever, and typhus fever.

With reference to small-pox he directed attention to the fact that two-thirds of the cases which had occurred during the last month, came from Philadelphia, where an epidemic of the disease seemed to be threatening. The importance of vaccination was shown, and he believed that it would be wise for the society to urge its performance.

A lamentable case was cited in which a member of the profession, in good standing, had been said to have stated that "the child" died as the result of vaccination, where the truth was that death occurred from *scarlet fever*. Should the statement be substantiated, he recommended that charges should be preferred against the member by the Committee on Ethics.

With reference to typhoid fever the mortality had been absolutely less during the last year than in any year during the last ten, with one or two exceptions readily explained by local causes. Dr. Janeway dwelt at some length upon the necessity of complete sewerage and drainage, thorough and complete disinfection of all discharges from the patient, all water-closets, privies, etc., if the best results were to be obtained in the treatment of that disease.

An interesting history of a few cases of typhus fever was given, in which the diagnosis was sustained by post-mortem examination.

The report took the usual course, and will be referred to the Committee on Hygiene of the State Medical Society.

Dr. J. C. Peters presented an additional report on the yellow fever fund, which showed that a small sum of money remained for distribution. The thanks of the society were extended to Dr. Peters for his untiring diligence in this benevolent work.

Dr. David Webster read the report from the Board of Censors, which was ordered to be entered upon the minutes.

The Society then adjourned.

Medical Statistics of Russia.—According to the report of the medical department, Russia had, in 1878, 13,475 physicians, 2,035 of which had the scientific degree of doctor of medicine, 5,100 male trained nurses (feldschers), 2,666 sage-femmes, 33 schools for trained nurses, 1,652 pharmacies. The list of physicians for 1878 was increased by 690 new names and decreased (by death) by 370.—*Vrachebn. Vedomosti*, 1880, No. 418.

[In this country, 1878, 59 medical colleges graduated 2,708 men. The number of physicians for the year being about 57,000. Population of this country is about half that of Russia.]

Correspondence.

HEREDITARY TOLERANCE OF DISEASE.

To the Editor of The Medical Record.

SIR—I am much indebted to my faithful friend, Dr. Reyburn, for a number of illustrations (THE MEDICAL RECORD, October 9, 1880, p. 417) of the correctness of the doctrines which I have previously set forth. These illustrations are sufficiently interesting to merit a more complete analysis than they have yet received.

The doctor's explanation of the mortality following the first epidemic of measles among the Sandwich Islanders is excellent as far as it goes, but it utterly ignores the fact that the knowledge "of hygiene or the proper medical treatment of such cases" constitutes no small part of that accumulated stock of hereditary influences by which the course of disease is modified wherever it becomes endemic. I do not refer now to the accumulated results of scientific observation and experiment, but to that popular stock of ancestral experience which cuts so large a figure in the domestic management of diseases with which the common people are familiar. But that this sort of hereditary influence is not alone sufficient is well shown by the experience of our army in 1862 and 1863. The soldiers to whom measles was then so fatal had the advantage of the best stock of accumulated scientific ideas that could be derived from ages of experience, and yet they died like Sandwich Islanders, or worse. Could they have had the measles at home, like other boys, no one doubts that their mothers would have nursed them successfully through the disease, perhaps without thought of scientific medical aid. Why this difference? Because, if they had been sick at home, like other boys who did not go a soldiering, they would have enjoyed the full benefit of all the hereditary influences by which they had been qualified to resist an attack of measles at home. But in the army they were placed under conditions entirely different from those in which they were born, and to which their race had become adapted. Consequently, all their ancestral inheritance of tolerance was lost to them. They found themselves placed under conditions for which the centuries had never prepared them, and they could not resist that combination of forces against which their constitutions had never been fortified. In like manner, when a city like Kiel, to which Dr. Reyburn has made allusion, receives a sudden and artificial increment of population, it always contains a great number of individuals dislocated from the environment to which their constitutions had, by influences hereditary and personal, become adjusted. Such persons, such families, yield a ready harvest for epidemics; and diseases, ordinarily benign, assume among them a great fatality. In course of time, however, the population, under the influence of natural selection, becomes adjusted to its new environment, and the mortality of epidemics, as well as their general pervasiveness, is correspondingly diminished. In this respect the visitations of small-pox in Europe before the days of Jenner contrast most instructively with the epidemics which swept away the American Indians. The Indians, unprotected by hereditary experience of the disease, were almost exterminated, while relatively the Europeans and the Asiatics were scarcely diminished in numbers by its almost constant prevalence. A better illustration of the value of hereditary protection could hardly be desired.

In this connection I may reply to Dr. Reyburn's question, "Why inoculation was abandoned if it be true that it is necessary to preserve the virus of epidemics in the community?" Simply because a method of securing a sufficient protection by a greater attenuation of the virus of small-pox was discovered. Inoculated small-pox represents the first degree of attenuation of small-pox virus, while vaccine disease represents its second degree of attenuation. It was once supposed that variola and vaccinia were separate and distinct diseases; but now we know, thanks to the labors of Mr. Ceeley and his pupils, that the last, which we propagate with such care, is merely small-pox modified by passage through the body of the cow. Had we not learned how to effect this additional attenuation, inoculation would still be our best means of protection against the virulent form of the disease.

Dr. Reyburn declares that in Great Britain "the mortality from scarlatina is just as great as it was a century ago." It is very likely that his assertion may be correct. Such a fact would not, however, militate against the doctrine of hereditary tolerance of disease. It is a matter of continual observation that in a rapidly increasing population, suddenly exposed to newly organized conditions of existence, scarlatina is much more prevalent than in old and stable communities where changes are almost inappreciable. Now, Great Britain has for a century past been the arena of the most remarkable *fermentation* and change that could unsettle any population. The introduction of steam has more profoundly altered the conditions of existence for the English than for any other people, and the British race has not yet had time to adapt itself to these profound modifications of its environment. Consequently, all the conditions for extensive prevalence of scarlatina among the British islanders have been maintained with great perfection. After a time an equilibrium will be established, and scarlatina will become less prevalent, without any reference to, or influence by, the new-fangled attempts at quarantine of the disease.

Dr. Reyburn asserts that "not only is heredity no protection from epidemics, but in some cases the mortality from them is actually increasing." He then calls attention to the increasing mortality from intestinal diseases which has been noticed in England. This fact, by itself, has no bearing upon the discussion. It merely serves to illustrate the fact that man can neither create nor destroy force. He can simply modify its direction and the mode of its incidence. "Stamp out" one disease, and another will inevitably spring up in its place. Diminish the prevalence of scarlatina, diphtheria occupies the field. Ravage a city with scarlet fever during the winter, fewer cases of cholera infantum will be numbered during the succeeding summer. There is for every population a certain mean about which all mortality tends to equilibrate.

My friend thinks that the prevalence of typhus fever in Spain and its absence in the United States are sufficient to prove that heredity and natural selection have no modifying influence over the spread of zymotic diseases. I cannot admire such logic. The question is not as the doctor seems to conceive it. The question is not whether heredity and natural selection will extirpate disease, but whether they will not evolve a population more tolerant of the diseases with which it is continually acquainted than a population for the first time exposed to the influence of the same diseases. The history of cholera in the portions of India where it is endemic throws much light upon the proper answer to this question. As the doctor has stated, it is among "the unfortunate pilgrims who perish every year of the pilgrimage" that the greatest mortality from cholera is observed. They are the people who are unacclimatized in the district—dislocated from the environment to which they had been adjusted by heredity and natural selection—thrown upon conditions for which they had never been adapted. Cholera must necessarily take such victims at an enormous disadvantage. The inhabitants of the cholera district only find themselves in a similar position of disadvantage when famine or war destroy all the defences which natural selection had built up.

A similar illustration is furnished by the experience of the colored people in the Southern States. Descended from a race which from time immemorial had been in process of continuous adjustment to the most deadly forms of malaria, the former slaves were remarkably tolerant of the malaria in our Southern States. It is noticeable that with an increasing distance from the parent stock in Africa, that tolerance which the American negro inherited from the African is diminishing. The process of natural selection relative to malaria is not as vigorous in this country as in tropical Africa.

The history of yellow fever teaches with equal clearness the value of natural selection and hereditary tolerance as agents for modifying the danger of disease. Among the native West Indians yellow fever is scarcely feared. The greatest mortality is among the newly imported foreigners who have never been adjusted to its causes. It is not among the creoles of Louisiana that this disease is most terrible; it is among the exotic inhabitants of Memphis, and in a population where the disease is never endemic, that its havoc is so frightful.

In fact, the influence of natural selection, and the hereditary resistance thus elaborated during successive generations, is so universal and so pervasive that, like the air in which we live, it is seldom noticed by superficial observers.

The explanation which Dr. Reyburn offers, to account for the comparatively uniform rate of mortality in England, is hardly satisfactory, though it does express certain of the causes which everywhere militate against the longevity of the race. Emigration from the British islands has been going on with great activity for two hundred years, consequently that factor can hardly be said to have exerted any extraordinary influence during the last forty years. Nor is the withdrawal of the vigorous emigrant class necessarily a source of enfeeblement to those who remain behind, and who find additional room and an increase of food as a consequence of diminished competition.

As for the "vast and alarming increase" of intemperance "in Great Britain of late years," the student of history knows that relatively to the increase of population this vice has long been diminishing in Great Britain. Compare the condition of the English a hundred years ago with their present condition, and it is evident that temperance has greatly increased during the intervening period. The authorities quoted by Lecky in his various historical works, exhibit a most instructive picture of that age in contrast with the present. As for the "wilful disobedience to the laws of health and hygiene by the people of England," I have no doubt that it is bad enough, but I do not believe that it has been any worse during the last forty years than during the preceding forty thousand years. And yet Dr. Reyburn tells us that the men of old could not compare with their descendants in physical vigor and size. Scientific men see in this the result of natural laws which are everywhere and always in operation. By these ever-acting forces the races which inhabit the earth are exactly adjusted to their environment, and a perfect equilibrium is thus maintained. The true way to improve the condition of mankind is to study the methods of nature, and to follow in the light of the experiments which have been so frequently performed on the grandest scale—for our benefit, one might almost say. In this connection the medical history of isolated races, like the Pacific Islanders, the annals of pestilential epidemics, the experiments of Ceeley in the attenuation of the virus of small-pox, the kindred experiments of Pasteur with fowl-cholera, and of Toussaint with charbon, are fraught with an importance not yet suspected by the average unscientific sanitarian. Would such people but attend to the well-known facts of chemistry, physiology, and biology, instead of urging a promiscuous activity like that of a bull in a china-shop, they would soon learn that "inaction" may often be the result of the highest wisdom.

One more extract from the eloquent author whom I have previously quoted, and I have done:

"Any one who has been, what Bacon recommends—a servant and interpreter of nature, no longer regarding the mere outside of things—has learned to look for the secret forces by which they are upheld. After patient study this chaos of phenomena, into the midst of which he was born, has begun to generalize itself to him; and where there seemed nothing but confusion, he can now discern the dim outlines of a gigantic plan. No accidents, no chance; but everywhere order and completeness. One by one exceptions vanish, and all becomes systematic. . . . . But, above all, he is struck with the inherent sufficingness of things, and with the complex simplicity of those principles by which every defect is being remedied—principles that show themselves alike in the self-adjustment of planetary perturbations, and in the healing of a scratched finger—in the balancing of social systems, and in the increased sensitiveness of a blind man's ear—in the adaptation of prices to produce, and in the acclimatization of a plant. Day by day he sees a further beauty. Each new fact illustrates more clearly some recognized law, or discloses some inconceived completeness, contemplation thus perpetually discovering to him a higher harmony, and cherishing in him a deeper faith.

"And now, in the midst of his admiration and his awe, the student shall suddenly see some flippant red-tapist get upon his legs and tell the world how he is going to put a patch upon nature! Here is a man who, in the presence of all the wonders that encompass him, dares to announce that he and certain of his colleagues have laid their heads together and found out a way to improve upon the Divine arrangements! Scarcely an idea have these meddlers got of what underlies the facts with which they propose to deal—as you shall soon find on sounding their philosophy—and yet, could they carry out their pretensions, we should see them self-appointed nurses to the universe! They have so little faith in the laws of things, and so much faith in themselves, that were it possible, they would chain earth and sun together lest centripetal force should fail! Nothing but a Parliament-made agency can be depended upon; and only when this infinitely complex humanity of ours has been put under their ingenious regulations, and provided for by their supreme intelligence, will the world become what it ought to be! Such, in essence, is the astounding creed of these creation-menders."

HENRY M. LYMAN.

CHICAGO, ILLINOIS.

SANITARY ADMINISTRATION AND EPIDEMIC DISEASE.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR—In the discussion which has been carried on in your columns on sanitary administration and epidemic disease I cannot but believe that Dr. Reyburn has allowed his interest in a favorite theory to warp his otherwise good judgment. It ought to be superfluous in this age to be compelled to show why heredity does necessarily influence disease. To do it is only to go over the known ground that has given the principle of natural selection its firm place among known scientific truths. The only question would seem to be, to what extent this influence is exerted, and whether in some cases it may not be relied upon to the exclusion of measures tending to repress or stamp out the disease. Dr. Lyman's illustration of the influence of vaccination on small-pox is hardly a fair one. There is no direct evidence to show that the unvaccinated individual of to-day is better protected from an attack of small-pox because his ancestors for the last five generations have been vaccinated, although, reasoning from analogy, it is quite probable that he is. But I think this country does furnish an illustration directly bearing on the subject. The population of New Mexico is made up of Americans and Mexicans, the native population being mainly a mixture of the ancient Aztec, or Pueblo Indian, with the Spaniard. Among the natives there has never been any attempt to prevent or avoid small-pox; the patients are never isolated, and in its treatment the contagious character of the disease seems to be entirely disregarded. This has been the case as long as we have any record, probably for two hundred years—long enough any way, considering the contagious and fatal character of the unmodified disease, to allow the principle denounced by Dr. Reyburn a fair test.

Now, this is the result: among adults the disease is very little regarded. Occasionally we hear of a severe and even fatal case, but in general it is not considered as a dangerous or even troublesome disease. It is different with children; the germs of the disease are generally to be found somewhere in the community, and a child susceptible of contagion is reasonably certain to be exposed, and among children the mortality is still considerable. Inoculation is practised to some extent, but vaccination is the exception, not the rule.

In the absence of statistics it is not right to draw general conclusions. I can only give my own opinion and belief, founded on my own observations during the last twelve years; and my belief is that the total mortality from small-pox, young and old, among the native population, does not exceed the proportionate mortality in a community protected by vaccination. It may be a little more.

This protection I attribute entirely to the influence of natural selection in persistently weeding out those subjects capable of contracting the disease in a severe or fatal form, and breeding from the survivors. Now, whether the present comparative immunity, with its prospect of complete protection, has *paid*, is a question for moral economists to determine. It has been gained at the expense of many individuals who would otherwise have passed away by fever, famine, or some one or other of the thousand different modes of torture by which nature puts an end to everything that lives, so that even, irrespective of present benefit, it would be hard to say now that they were not mercifully destroyed.

L.

LA MESILLA, NEW MEXICO, October 16, 1880.

THE MEDICAL LAW OF KANSAS.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR—In the RECORD of the 16th ult., in commenting on the recent publication of Dr. Hardwicke, you gave *his* list of states "that have no medical laws whatever," in which is included the State of Kansas. If Dr. Hardwicke simply wished to be ironical, he is, perhaps, correct, but literally he is not. *We have* a law regulating the practice of medicine in this state, passed by the last legislature, which went into effect June 1, 1879. By the operations of this law three medical boards were recognized, viz., Regular, Homœopathic, and Eclectic, to be appointed by their respective state societies as having authority to license the following persons to practice medicine: first, physicians having a diploma from a medical school in good standing; second, persons passing an examination before the Boards. By a paragraph in the law, persons who had been in continuous practice within the state, for five years, were exempted from these provisions.

It will be observed also that since the 1st of April, 1880, the Boards have no authority to grant license to others than graduates of medical institutions. The Boards received from candidates, as fees, in case of diploma five dollars, where examination was made, twenty dollars. These fees, after paying salary and expense of Board, were turned into their society. Now as to its practical workings:—I have before me a report of the examining board of the Kansa Medical Society, made to that society at its last annual meeting in May, 1880, from which it appear that up to that time 663 certificates to practice had been issued by the Board to graduates of medica schools, 148 persons had been examined by the Board and received permit to practice, and 11 persons had failed in examination. The report say "many of whom we found ignorant of the firs principles of medicine." The law provides that a applicant failing to obtain a permit from eithe Board is debarred from reapplying for one year, th "report" on this subject says: "They (the Electi Board) have also issued certificates to numerou persons who were previously rejected by you Board," and this in direct violation of the words o the statute, and further the "report" reads, "W venture the remark that no reputable physician ha taken a certificate from the Eclectic Board." Thi *remark* will doubtless be taken *cum grano salis* b persons outside the profession, and is not entirel correct, but unfortunately very nearly so.

Shortly after the law went into effect, the bullet headed individual who holds the office of Attorney General to the state (and who pre-eminently confirm the oft-repeated assertion that Kansas was neve guilty of electing a lawyer to that position), formulated an "opinion" that the Kansas Medica

Society "had no legal existence" (having been chartered while the state was a territory), and was therefore incompetent under the law to grant permits to practise.

This *opinion* was at once published broadcast over the state by the Eclectic Board who had obtained it, who also addressed circulars to the physicians that had been licensed by the Kansas Society, notifying them that they were practising in violation of the law, and *offering to issue an Eclectic Board license on receipt of the proper fee.*

The Eclectic Board had become, it seems, a sort of "home for friendless," and in *consideration* of the fees allowed by law threw its protecting mantle over the irregulars of all shades and complexions. The *report* says: "twenty-nine applicants were rejected by the Eclectic Board," a number of whom *have since* received certificates from said board. It is possible that their legal adviser, the Attorney-General, furnished them another "opinion" that permitted this. From my knowledge of the personnel of some of their licentiates, I can conceive nothing but a *deficiency in the consideration* that would cause the rejection of a candidate.

The salutary effects of the law, thus far, has simply been *nil*; it has probably not prevented fifty persons in the state from practising medicine. Its future effects are yet to be seen. The granting of "permits to practise" on examination by Boards of different schools of medicine is pernicious in the extreme, as has been fully demonstrated here, and although it might work hardship on sparsely settled communities to be deprived of the service of a physician by reason of his not being a graduate, in a short time this would have been remedied and the enforcement of proper laws would have sent those who really possessed qualifications for the practice of medicine to the schools for diplomas and relieved the state of its quacks and impostors.

I remain
Yours very truly,
M. F. Leary, M.D.

Gaylord, Kansas, Oct. 19, 1880.

Obituary.

EDOUARD SEGUIN, M.D.,

NEW YORK.

Dr. Edouard Seguin died at his residence in this city on the 28th ult., at the age of sixty-eight years.

He was born at Clamecy, France, January 20, 1812. Soon after completing his education at the colleges of Auxerres and St. Louis, in Paris, he began his studies upon the physiological education and training of idiots, a study of which he was the originator, and in which he became the master. It was in 1837 hat he first undertook the treatment of an idiot boy, n the study of whose case he benefited from the advice of Itard and Esquirol, his teachers. Before 839 Dr. Seguin instituted the first school for idiots, which was the parent establishment of seventy-five nstitutions for idiots since opened in civilized countries. Of these, the eleven schools in the United States which he helped to organize are among the most prosperous. Shortly after the revolution of 848 Dr. Seguin came to this country, spending the ensuing ten years in Ohio, at first in Cleveland, and atterly in Portsmouth. He subsequently revisited France, and on returning to the United States settled in this city, where he completed his studies, graduating an M.D. at the University College in 1861. A year later he was elected a member of the American Medical Association. In 1866 he began to devote much of his time to a special study of medical thermometry, and to his work and writings in this direction the profession of this country is greatly indebted for the introduction and popularization of the clinical thermometer.

In 1873 Dr. Seguin was made United States Commissioner on Education at the Vienna Exposition. At this time he examined the educational systems in nearly all parts of Europe, but paid especial attention to the kindergartens of Germany, and the *salle d'asyle* of France. His studies included also the education of deaf-mutes and of idiots. To this work he brought the qualities of intelligence, enthusiasm, and extensive scientific knowledge, and his final report forms one of the most valuable of educational documents. It has been reprinted and has gone through several editions, the last of which was published quite recently. His studies at that time led to the production of his memoir on Garden Schools, recently read before the New York Academy of Sciences. In this he proposed to incorporate with our existing public school system a method of outdoor training, to develop alike the muscles, the special senses, and the intellectual faculties, by means of natural history studies at the Park. The essay met with a cordial reception by the Academy, but it was in advance of the time, or at least of our municipal politics, and it awakened no general interest.

Of late years, Dr. Seguin had been interesting himself in efforts to introduce the metric system into medicine in this country. His work in this direction is familiar to all. As delegate from the American Medical Association in 1879, he did much toward starting the movement in England. He also presented the subject, during the same year, at the International Medical Congress, and at the French Association for the Advancement of Science.

A list of the writings of Dr. Seguin best gives an idea of the extent and direction of his studies. They are as follows: "Hygiène et Education des Idiots," 1843; "Images Graduées à l'Usage des Enfants Arriérés et Idiots;" "Traitement Moral, Hygiène, et Education des Idiots et des autres Enfants Arriérés," 1846; "J. R. Pereire, Premier Instituteur des Sourds et Muets en France," 1847; "Historical Notice of the Origin and Progress of the Treatment of Idiots," translated by Dr. J. S. Newberry, 1852; "Idiocy and its Treatment by the Physiological Method," revised by a son of the author, Dr. E. C. Seguin, in 1866; "New Facts and Remarks Concerning Idiocy," 1870; "Medical Thermometry," 1871; "Prescription and Clinic Records," 1865–1877; "Mathematical Tables of Vital Signs," 1865–1877; "Thermomètres Physiologiques, Manual of Thermometry for Mothers, Nurses, Teachers," etc., 1873; "Official Report on Education at the Vienna Exhibition of 1873," published in 1875; "International Uniformity in the Practice and Records of Physic," and "Medical Thermometry and Human Temperature," 1876; "The Physiological Training of the Idiot's Hand," 1879.

Although Dr. Seguin was intelligently informed on all medical matters, and although he interested himself specially at times in medical thermometry, the metric system, and other subjects, his claim to permanent remembrance will lie in the work he did for the education of idiots. He was the first to introduce a system of intelligent training for these unfortunates, based upon thorough knowledge of their physiological and anatomical peculiarities. The problem which, at the very first, he set before himself, was to develop to its utmost the scant nervous centres of the idiot. To this problem he brought an unflagging enthusiasm, constant industry, a well-stored and original mind; and his work resulted in the wide establishment of a system of educational training which will remain a perpetual monument to him. By an enthusiasm that could not be dampened either by lack of sympathy or the approach of old age; by an originality which could conceive and an ability which could create a new and beneficent educational system, Dr. Seguin has won a name which will not be forgotten.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from October 24, 1880, *to October* 30, 1880.

Baily, E. I., Lieut.-Col. and Surgeon. When relieved by Surgeon Moore, to proceed to Wilmington, Del., and report, by letter, his arrival to the Surgeon-General. S. O. 232, A. G. O., October 28, 1880.

Moore, Jno., Major and Surgeon. Relieved from duty with Army Medical Examining Board in New York city, and to report in person to Commanding General, Department of the Columbia, for duty as Medical Director of that Department. S. O. 232, A. G. O., October 28, 1880.

Spencer, W. C., Major and Surgeon. Assigned to duty at Fort Snelling, Minn. S. O. 129, Department of Dakota, October 25, 1880.

White, C. B., Major and Surgeon. To report in person at the expiration of his present leave of absence to the Adjutant-General of the Army, for special duty in connection with the Recruiting Service. S. O. 229, A. G. O., October 25, 1880.

Caldwell, D. G., Capt. and Asst. Surgeon. Assigned to duty as Post-Surgeon at Fort Fred. Steele, Wyo. Ter. S. O. 98, Department of the Platte, October 20, 1880.

Wood, M. W., Capt. and Asst. Surgeon. At the expiration of his present leave of absence, to report in person to Commanding General, Department of the East, for assignment to temporary duty. S. O. 232, C. S., A. G. O.

Burton, H. G., 1st Lieut. and Asst. Surgeon. Granted leave of absence for two months, with permission to apply for one month's extension. S. O. 230, A. G. O., October 26, 1880.

Cunningham, T. A., 1st Lieut. and Asst. Surgeon. Granted leave of absence for six months, with permission to go beyond sea. S. O. 227, A. G. O., October 22, 1880.

Intestinal Obstruction for Seventy Days, from Stricture of the Rectum.—Dr. D. W. Coble, of Westerville, Ohio, reports a case of the above occurring in a farmer aged twenty-eight. The stricture was annular, non-malignant, and apparently the result of the dysenteric ulcerations. Strange to say, there was no stercoraceous vomiting during the whole sickness. Lumbo-colotomy was performed by Dr. J. W. Hamilton, of Columbus, Ohio, but too late to save the patient.

Dr. Roosa's Lecture on Constitutional Diseases.—Dr. Geo. T. Stevens writes: In the Record of October 9th is published a lecture by Dr. D. B. St. John Roosa in which he criticises certain of my views that have appeared in various publications. To sustain and strengthen his criticisms, he cites a case which he attributes to me and which he calls a "specimen case," and "which," he says, "induced me to speak to you on this subject."

In a letter from the author of the lecture I am informed that the case thus recited is one concerning which I have perfectly clear recollections; and I am prepared to say that the advice which Dr. Roosa represents me as having given was never rendered by me in this case.

It is hardly necessary for me to criticise further a paper the central supposed fact in which is a case concerning which the author had no correct information; and it is perhaps not surprising that an author who bases his criticisms upon supposed advice, of which he is only informed by rumor, should suspect that the views of others may be "founded upon incorrect observations."

The Cartright Lectures.—The first course of the Cartright lectures of the Alumni Association of the College of Physicians and Surgeons will be given by Prof. Roberts Bartholow, of Philadelphia, at the college on Tuesday evenings, November 9th, 16th, 23d, 30th, and December 7th and 14th.

Reception by the Council of the National Association for the Protection of the Insane, and the Prevention of Insanity.—There will be a reception given by the above council at parlor (D. R.), Fifth Avenue Hotel, Thursday evening, November 11th, at eight o'clock. A paper giving an account of visits to many of the large asylums in England, Scotland, Germany, and France, will be read by Dr. G. M. Beard. There will be remarks and discussion by other members of the council and society. Among those expected to be present are: Dr. H. B. Wilbur, of Syracuse; Dr. Nathan Allen, of Lowell; Dr. E. C. Seguin; Dr. J. C. Shaw; Dr. Putnam-Jacobi; Hon. Vincent Collyer; A. A. Chevaillier, and others.

All who feel any interest in the vital questions relating to the present rapid increase of insanity, and the treatment of its victims, are cordially invited to be present.

American Academy of Medicine.—The next meeting of the American Academy of Medicine will be held in this city on the third Tuesday in September, 1881.

Original Communications.

AN ACCOUNT OF A SERIES OF COMPLICATED CASES OF TYPHOID FEVER TREATED AT THE EPISCOPAL HOSPITAL, PHILADELPHIA.

Service of Dr. Louis Starr.

By T. H. CATHCART, M.D., Ph.D.,

EX-RESIDENT PHYSICIAN, EPISCOPAL HOSPITAL.

The following cases of typhoid fever, which I wish to present for consideration, show complications which, if not unique, are still uncommon. They have been selected from a number treated in the wards of the Episcopal Hospital, Philadelphia, during my residence there as an interne. It is my desire to simply place them on record, to establish the fact that such departures from the ordinary ensemble of typhoid fever symptoms do occur, to give to each just that amount of consideration to which its importance entitles it, and not to advance any theory or new line of treatment for the subject in question.

Case I.—*Typhoid fever complicated with hysteria and vicarious menstruation.*—Ida W——, aged seventeen years, a domestic, was brought to the hospital on December 25, 1879. At the time of admission she was in a semi-unconscious condition, and the only history that could be obtained from her friends was that the attack had begun one week before with malaise, headache, fever, and diarrhœa; that she had been greatly agitated when told that she was to be taken to the hospital, and had soon after passed into the semi-unconscious state. Her body was well nourished, her skin hot and dry, her face flushed, and her pulse feeble. Her tongue was moist, covered with a heavy white fur in the middle, and tremulous. Her abdomen was distended, and there was slight gurgling, on pressure, in the right iliac region. The typhoid eruption was well marked. The lungs and heart were healthy. The urine contained a slight trace of albumen. On the evening of admission the axillary temperature was 105° F., the pulse 102 and feeble, and there was active delirium. A diet of milk and beef-tea was ordered, four cachets (each containing five grains of sulphate of quinia) were administered in the course of an hour, and ten grains of carbonate of ammonia were given every three hours during the night.

Next morning, December 26th, the temperature had fallen to 103°; the pulse was very weak. She was apparently comatose, but, her eyes being wide open and fixed, the pupils dilated, and the lids tremulous, her face had rather a hysterical expression. After great coaxing she could be induced to swallow a small quantity of milk, but there was so much delay and difficulty about the process that both food and medicines were administered by the rectum. The bowels were loose. The urine was now free from albumen.

On the following day, December 27th, the patient, while still refusing to speak, to protrude the tongue, or to swallow food, was so restless that it was necessary to remove her from the ward and allow her to lie upon a mattress placed on the floor in a separate room, and even then it was difficult to keep her covered with the bed-clothing. In this condition, seemingly unconscious of all that took place about her, she remained until the evening, when her mother, who had not visited her before, came into the room. The girl instantly recognized her, spoke rationally, giving an account of many of the occurrences of the previous twenty-four hours; eagerly swallowed milk and punch, taking the cup from her mother's hands; and voided a quantity of colorless urine. During the night, though responding to questions only in monosyllables, she put out her tongue when requested, and swallowed freely; as morning approached she relapsed, and so remained until her mother reappeared in the evening.

On December 29th she was much more quiet, and was put into bed again. From this time there was no trouble in getting her to swallow food (milk, beef-tea, milk-punch) and medicine (15 gtt. tr. digitalis thrice daily, and five grains of carbonate of ammonium every four hours), quinine being administered by the rectum. Her bowels continued loose for five or six days. The hysterical complication was occasionally evinced by "laughing-spells," though there was no return of the grave symptoms. The temperature ranged from 103° in the morning to 105° at night, and the pulse from 104 to 120 until January 1st, the beginning of the third week of the fever.

During the third and fourth weeks there were no unusual symptoms, the fever gradually subsiding, and the hysterical manifestations entirely disappearing. On January 15, 1880, the commencement of the fifth week, the temperature was normal and the pulse was strong and full, counting from 80 to 100 beats per minute. On January 23d the patient was seized with cramps in the lower part of the abdomen and inability to retain her urine. The temperature rose from normal to 100.5°, and the pulse became frequent. Twenty-four hours later she vomited twelve ounces of bloody liquid and complained of weakness and abdominal tenderness. Now, as there had been no hemorrhage from the bowel, nor from the nose into the pharynx, it was difficult to fix upon the cause of the hæmatemesis, until it was ascertained that it was the time in the month for the catamenial flow; the bleeding was then considered to be vicarious. The subsequent course of the case was a steady progression toward health. She left the hospital strong and well—weighing 111 pounds—on March 10, 1880.

The clinical history of this case is interesting from the fact that in none of the journals or text-books have I been able, after diligent search, to find any record of the occurrence of vicarious menstruation during the course of typhoid fever, nor any statement of the existence of hysteria as a complication of the latter. That the semi-comatose state was really hysterical in nature was demonstrated by the girl's rapid transit from a condition of oblivion to one of complete consciousness, in which she recognized her mother, talked rationally, and swallowed freely. Minor items in proof are the mode of onset and cause of the first attack, the peculiar expression of the face during its continuance, and the passage of a large quantity of colorless urine at its termination. Dr. Gairdner ("Clinical Medicine," Edin., 1862) has called attention to a condition simulating this, and Murchinson ("Continued Fevers," Lond., 1873) states that he has met with cases answering more or less to his description; but nowhere have I been able to find any account of hysteria and vicarious menstruation complicating the progress of an attack of typhoid fever.

Case II.—*Typhoid fever followed by pleurisy.*—Henry K——, aged twenty-two years, a native of

Germany, was admitted to the medical ward, Sept. 1, 1879. He was a butcher by occupation, temperate in his habits, and had had only one illness since childhood, namely, an attack of tonsillitis in the spring of 1878.

The typhoid fever began four days before admission. It was ushered in by rigors, lassitude, headache, epistaxis, and diarrhœa. It ran a course of moderate intensity, the axillary temperature never running higher than 104°, the pulse ranging from 96 to 100 beats per minute, and the nervous system being little affected. The abdominal symptoms, however, were very well marked. The treatment consisted of a prescription containing four grains of sulphate of quinine with fifteen minims of dilute muriatic acid, and a mixture of five minims of oil of turpentine and an equal quantity of dilute muriatic acid, administered alternately at intervals of two hours; the diet was exclusively milk, and from two to six fluid ounces of whiskey in the form of milk-punch were given daily.

On September 20th, 21st, and 22d the temperature was normal, ranging from 98° to 98.5°, and convalescence seemed to be well established. On September 23d, however, there was a sudden change in his condition. The face became pale and anxious, he moved about uneasily in bed, and complained of a sharp pain in the left hypochondriac region. The respirations were shallow and much increased in frequency, counting 44 per minute, but a physical examination of the heart and lungs furnished negative results. The abdomen was tense and tympanitic, there was tenderness on pressure along the left costal border, and the abdominal respiratory movements were suppressed. His tongue was coated, there was anorexia, and during the preceding twenty-four hours there had been one scanty evacuation from the bowels. The pulse rose from 84 in the morning to 120 in the evening, and the temperature from 98.5° to 104° ; notwithstanding this rise in the temperature, several times during the day the hands and feet felt cool. Peritoneal inflammation being suspected, one grain of opium was ordered every three hours, a light flaxseed poultice was applied over the lower part of chest and the whole of the abdomen, and the milk diet and milk-punch were continued as before.

On the 24th the temperature fell several degrees, but the pulse became more frequent—136 per minute. The coolness of the extremities was no longer noticed, the respiration was less hurried, and as the opium asserted its influence he grew much less restless. On account of the frequency and weakness of the pulse, moderate doses of digitalis were added to the other treatment.

On the 25th the temperature at both the morning and evening observations was 100°, the pulse 124–128, and the respiration 28. Tenderness on pressure was still present in the left hypochondrium, though the abdomen was more flaccid, and there was some movement of the abdominal muscles on the right of the median line in respiration; over the lower third of the left chest, antero-laterally, a loud, rasping friction-sound and a well-marked friction-fremitus were perceptible, and percussion elicited diminished elasticity and transmitted gastric tympany; the cardiac apex was elevated and pushed to the right.

September 27th, while there was little change in the temperature and pulse, the repirations became more frequent. On the left side of the chest there was flatness and increased resistance on percussion from the third to the seventh rib, and below this point increased resistance and tympanitic percussion-sound; near the upper margin of flatness friction-sounds and fremitus still existed, and at the base there was tubular breathing. The heart was forced still farther to the right, the apex-beat being situated just to the left of the left edge of the sternum, in the fourth interspace. There was much improvement in the appetite, and the abdomen was more natural in appearance, the abdominal respiratory movements being re-established. The pain was less and the opium was reduced to half a grain every three hours.

September 30th the opium was discontinued and the prescription containing quinine and dilute muriatic acid resumed. From this date to October 15th the pleuritic effusion gradually disappeared and the heart returned to its normal position. The temperature varied from 98° or 99° in the morning to 100° or 101° in the evening, the pulse gradually fell to 96, and the respirations numbered from 20 to 28 per minute. Despite every precaution a large bed-sore formed over the sacrum. After October 15th the temperature fell to the normal line, and he improved steadily, but very slowly. The doses of digitalis and the stimulants were gradually reduced, the diet cautiously increased, and the quinine mixture steadily continued.

He left his bed for the first time on December 1st, and weighed 117 lbs. He was discharged December 30th in excellent general condition; the heart was in its normal position, no evidences of the pleuritis remained, the bed-sore was entirely healed, and he weighed 136 lbs.

Pleurisy with more or less effusion is a sequel of rather rare occurrence. Louis[*] reports that it existed in 2 of 46 of his cases; Murchison[†] in 6 out of 19; and Liebermeister[‡] states that in 1743 cases of typhoid fever treated in the Basle Hospital it was observed in 64. It is apt to terminate, unless early recognized and treated, in empyema, and of course the prognosis is made by its presence more unfavorable and uncertain. As causes, irritation due to the blood being charged with fever-poison, the adynamic state of the system, and exposure to draughts of air, may be cited. Cold baths, wet packing, or sponging, do not, according to the extensive observations of Liebermeister, favor its development, but rather tend to make it—as well as other affections of the respiratory apparatus—occur more rarely, and cause it to run its course with less severity than any other treatment which is not antipyretic.

Case III.—*Typhoid fever with albuminuria.*—Jacob ——, aged nineteen years, a butcher by occupation, was admitted to the hospital, October 13, 1879. He had suffered from bronchitis during the winter of 1878, but stated that he had never had any other severe illness. The first symptoms of typhoid fever were noticed two weeks before admission, though he did not become ill enough to quit work until about one week later.

When first seen, on October 13th, his face was flushed, both the upper and lower eyelids were puffy, he complained of headache, thirst, and anorexia, and his tongue was heavily coated in the centre with a white fur. The bowels were loose, and there was some abdominal distention, with tenderness and gurgling in right iliac region. The axillary temperature at 6 P. M. was 105.3° and the pulse 94.

The morning urine of October 14th was acid, had a spec. grav. of 1.016, was cloudy and highly albuminous; no casts could be found on careful microscopic examination.

---

[*] Recher. sur gastro-entérite. fièvre putride, adynamique, Paris, 1829.
[†] Murchison, op. cit., p. 634.
[‡] Ziemssen's Cyclop. of Medicine, New York, 1879, p. 173.

The type of the fever proved to be quite severe. The evening temperature for the first four days of treatment was above 104°, and for the succeeding eight days above 103°, the morning remissions being slight. The pulse ranged about 90, and only on one occasion reached 108. The eruption was well marked. There were several profuse hemorrhages from the nose, a harassing, spasmodic cough, resulting from catarrh of the larger bronchial tubes, and a tendency to wakefulness and occasional delirium. The tongue soon became dry and the teeth covered with sordes; the abdominal distention increased, and the diarrhœa gave place to constipation. There was rapid loss of flesh.

The patient was fed entirely upon milk; he had four fluid ounces of whiskey, in the form of milk-punch, during the day, a mixture of sulphate of cinchonidia and dilute muriatic acid at intervals of four hours, and also, in the second and third weeks of treatment, five drops of oil of turpentine with an equal quantity of dilute muriatic acid every four hours, alternating with the cinchonidia mixture. Hypodermic injections of $\frac{1}{6}$ to $\frac{1}{4}$ gr. of sulphate of morphia were administered when required to produce sleep, and enemata were employed every twenty-four or forty-eight hours when the bowels became confined.

The temperature commenced to remit on October 29th, the beginning of the fourth week of the fever, and fell to the normal line on the 4th of November. The diet was now cautiously increased; he was placed upon citrate of iron and quinine, and a small quantity of sherry wine (four fluid ounces) was substituted for the punch. He left his bed for the first time on December 2d; at that time he weighed 131 pounds, and the albumen had entirely disappeared from his urine.

After this he improved rapidly. On December 30th, the date of his discharge, he weighed 160 pounds, and felt perfectly strong and well. His eyelids had still rather a full appearance, which, he said, had always been the case. The urine was voided freely, was clear, acid in reaction, with a specific gravity of 1.022, contained neither albumen nor other abnormal ingredient, and was free from casts.

The presence of albumen in the urine of typhoid fever patients has been mentioned by Solon[*], Friedrich[†], Griesinger[‡], and many others. In a list[§] of 547 recorded cases it was present in 157, or in 28.6 per cent. Albuminuria is seldom observed before the second week, and is most apt to appear coincidently with cerebral symptoms. In typhus fever it generally occurs earlier and lasts longer. Cases in which the albuminuria is great and persistent generally run a severe course, and the prognosis is *pari passu* more indeterminate and grave. It is to be referred to the febrile attack, provided there be no history of antecedent renal disease. Whether any peculiar structural alteration of the kidneys is produced is uncertain. Most probably not, or we should not find the evidences of kidney lesion so transitory in their character. It is due to the altered condition of the blood and to hyperæmia of the kidneys, induced by the pyrexia, and is indicative of an obstruction to the channel by which the increased amount of urea and other products of retrogade tissue-metamorphosis are eliminated from the system. The prognosis[*] is always dependent upon the quantity and the date of appearance of the albumen; thus, the earlier its appearance, the larger its quantity and the longer its persistence, the more unfavorable will the prognosis be, and *vice versa;* hence the importance of daily examinations of the urine during the course of the fever. In this patient, the albuminuria being associated with a natural fulness of the eyelids, closely simulating œdema, pointed at first to some structural lesion of the kidneys, a suspicion dispelled by the subsequent course of the case.

CASE IV.—*Typhoid fever followed by diphtheria.*—G. A——, aged twenty-one years, a Norwegian sailor, was admitted to the medical ward on October 8, 1879. His habits were temperate, and his health had been good until six days before he entered the hospital, when the first symptoms of typhoid fever were noticed. The fever was very mild in type, the evening temperature in the axilla ranging about 102°, and only on two occasions reaching 103°, while the morning remissions were well marked, usually amounting to 2° or 2.5°. The pulse was, if anything, slower than normal, varying from 68 to 76 beats per minute. There was some occasional hebetude, a constant sense of muscular weakness, partial anorexia, with moderate abdominal distention, and gurgling in the region of the cæcum, but with a tendency to constipation. The eruption was ordinarily well developed. The urine was normal. The treatment comprised a milk diet, two fluid ounces of sherry wine daily, and a prescription containing four grains of sulphate of cinchonidia and fifteen minims of dilute muriatic acid, administered every four hours.

On October 24th, the twenty-second day of the disease, the temperature was normal and remained so on the 25th, 26th, 27th, and 28th. During these five days the patient's general condition was good, and he had a much better appetite, though he made some complaints of headache and weakness. The diet was increased by the addition of a moderate quantity of farinaceous food; no other change was made in the treatment, and he was not allowed to leave his bed.

On the 29th the headache was more intense, and there was a recurrence of fever, which rapidly increased as evening approached, the temperature at 6 P.M. being 105°, and the pulse 132. The milk diet was resumed. On the 30th and 31st, and on November 1st, the following notes were made:

October 30th, 8 A.M.—Temperature at six o'clock this morning, 104°; pulse, 124. Face dusky, with a peculiar, anxious expression; headache intense; thirst great; tongue heavily coated; appetite greatly impaired; abdomen slightly distended, gurgling and tympany in right iliac region. Has had two liquid stools during the night. At 12 M., while swallowing a mouthful of water, an expression of pain was observed to pass over his face. Pressure beneath the angles of the jaw caused pain, and an inspection of the pharynx showed redness of the half-arches, redness and moderate enlargement of both tonsils, and the presence of two white patches, scarcely larger than pin's heads, upon the left tonsil. The breath had a heavy, offensive odor. Chlorate of potassium was ordered, together with the cinchonidia mixture. Directions were given to wash out the mouth every hour with a solution of the potassium salt, and twelve fluid ounces of milk-punch (one to two) were substituted for the sherry. At 6 P.M. the temperature was 105.3°, the pulse 116. The bowels had been evacuated four times during the day and the stools were liquid. The abdomen was distended and tender.

[§] Murchison, op. cit., p. 532.

[*] *Vide* Brit. and Foreign Med.-Chirur. Rev., 1852. p. 316; Prag. Viegteljahrsch.. 1847. iii., p. 28; Schmidt's Jahr., 1868, Bd. 131, S. 44; Deutsch. Archiv f. klin. Med., 1866; London Med. Times and Gazette, vol. i. 1864, pp. 590, 666.

October 31st.—Morning temperature, 103.5° (perhaps reduced by 30 gr. acid. salicylic., administered in the night); pulse, 134, very weak. Face pinched and livid. The whole of left tonsil covered by a diphtheritic membrane; deglutition difficult. Complains for the first time of pharyngeal and abdominal pain. Retention of urine. Evening temperature, 104.6°; pulse, 140, thready. Five large liquid stools during the day.

November 1st.—In a condition of collapse. Skin livid and bathed with sweat. Hands and arms up to the elbows cold. Temperature, 101°; pulse not perceptible in radial or brachial arteries. Consciousness retained. Death occurred at 11 A.M.

An *autopsy* was made six hours after death. The surface temperature to the hand was higher than it had been for several hours before death. Both cavities of the heart contained firm ante-mortem clots, and the blood in the veins was more fluid and much darker in color than usual. The lungs were healthy. The mucous membrane of the stomach and small intestine presented evidences of congestion. The patches of Peyer were indurated and swollen, and several of those toward the lower end of the ileum showed cicatrizing ulcers. The mucous membrane of the cæcum and colon was thickened and studded with follicular ulcers. These ulcers extended only as far as the muscular layer; they were about one-eighth of an inch in diameter, with moderately cleancut edges and yellowish white floors, and were most numerous in the cæcum. The mesenteric glands were enlarged.

The liver, kidneys, and spleen were engorged with blood, the latter being about twice its usual size.

The above case recalls the theory advanced by Hunter,* that "no two of the so-called specific diseases can exist in the same person at the same time." A great deal of controversy has been held on this subject at various times. Much has been said for and against it, and a number of able authorities and skilled clinicians, notably Murchison,† have adduced cases and given a *résumé* of evidence in point to prove its falsity. Without going into the details of the discussion, it may be stated that the fact is proven that two specific diseases can coexist in the same individual, and that, furthermore, each will preserve its own characteristic symptoms. An analysis of this case would lead one to suppose that the diphtheria commenced after the typhoid fever was over (twenty-eight days); but when it is recollected that the patient was so situated that he could not have received the diphtheritic contagion after coming under observation (since there was no case of diphtheria in the ward at that time, nor had there been any in the hospital for many months), we are led to believe that it must have been absorbed before he entered the hospital. In other words, that the two specific poisons must have been taken into the system simultaneously, one to develop, the other to remain latent; and that that disease first manifested itself whose poison was received in greatest quantity or virulence. In the case detailed by Murchison,‡ the diphtheria appeared after the thirty-fifth day from the beginning of the typhoid fever.

CASE V.—*Typhoid fever with sudden and great rise of temperature during convalescence, caused by impaction of the rectum.*—Harry C——, aged twenty-seven years, a brakeman, was admitted to the men's medical ward of the Episcopal Hospital on November 24, 1879. He stated that he had always enjoyed good health until the beginning of the present attack, about November 10th. This illness proved to be typhoid fever.

The fever pursued a regular course, and was mild in type. The eruption and the abdominal symptoms were well marked, and the spleen was enlarged. The pulse throughout was slow and occasionally dicrotic. The axillary temperature, which on one occasion alone—the evening of the day of admission—reached 104.5°, fell to the normal line on December 11th, the seventeenth day of treatment and about the twenty-first of the disease, the patient having taken to his bed on November 20th. There were no nervous symptoms except slight hebetude. The treatment consisted of a milk diet, stimulants in moderate quantities, cinchonidia with dilute muriatic acid, and oil of turpentine. For a short time before convalescence became established, a tendency to sluggishness of the bowels was observed.

On December 13th two stools were obtained by a dose of castor-oil aided by an enema. These were large, formed, putty-like in consistence, and light yellow in color, the act of defecation being difficult and somewhat painful.

December 14th.—No evacuation. Temperature: morning, 98°; evening, 100°; pulse 68 to 76. Complained of coldness of extremities. Treatment: liquid diet (milk and beef-tea), fifteen fluid ounces of milk-punch, four grains of cinchonid. sulph. with fifteen minims ac. muriat. dil., three times daily.

December 15th.—No evacuation; belly indolent; tongue becoming coated again. Anorexia and nausea; skin hot, but moist. Temperature: morning, 98°; evening, 101°. Pulse: morning, 68; evening, 80, very feeble. Quantity of food reduced, cinchonidia mixture stopped, and an effervescing draught ordered every two hours.

December 16th.—No evacuation; some distention and tenderness of the abdomen, with dulness and a feeling of resistance in the left iliac fossa. Tongue coated white; breath heavy; face anxious in expression; sense of general discomfort and restlessness, and disturbed sleep. Temperature: morning, 103°; evening, 100.5°. Pulse: morning, 96; evening, 76. Treatment continued, with the addition of a cacao-butter suppository every six hours, and a large enema—the latter to be repeated if necessary.

December 17th.—Bowels evacuated in the early morning, stool very large and passed with great difficulty; its expulsion was followed by a short period of prostration. Belly less prominent—the tenderness has disappeared; a few lumps of fæces can be felt above the brim of the pelvis on the left side. Had a second stool at 11 A.M. At 6 P.M. his general condition was much improved; tongue cleaning, appetite returning, and face natural in expression. Temperature, morning, 96°; evening, 98°. Pulse, 76.

On the 18th the effervescing draught was discontinued and the cinchonidia mixture resumed.

For the succeeding eight days the temperature remained normal and there was a steady improvement, though an occasional laxative or an enema was required to keep his bowels open.

On the 25th it was noted that the patient was doing well. He had one large, lumpy stool, brought about by a dose of castor-oil given the day before.

---

* Hunter's works. Palmer's edition. Vol i., p. 313.

† Brit. and Foreign Med. Chir. Rev., 1859, p. 178.

‡ Op. cit., p. 585.

He consumed nearly eight pints of milk daily, together with twelve fluid ounces of beef-tea.

On the 26th there was no passage; his tongue was lightly coated; his breath was heavy; there was anorexia, thirst, and slight nausea. On palpation a few fecal masses were detected along the course of the sigmoid flexure. Temperature: morning, 98°; evening, 98°. Pulse: morning, 68; evening, 104. At 9 P.M. he had a severe chill; the thermometer at that time indicated 105°, and the pulse counted 104.

On the 27th, at 4 A.M., the temperature was still 105°. The same treatment was instituted as on December 16th. At 9 A.M. the temperature had fallen to 104°, and at 6 P.M. to 102°, while the pulse fell from 112 to 86. He vomited several times during the day.

On the 28th there was a large light-colored, formed stool. Temperature, morning and evening, 99°; pulse 86 to 88.

After this time convalescence proceeded uninterruptedly, though slowly, the patient not being discharged fit for work until February 13, 1880.

Impaction of the rectum, with consequent rise in temperature during convalescence, is a clinical feature in the course of typhoid fever which merits our attention and study. No reference is made to it in Liebermeister's exhaustive article in "Ziemssen's Cyclopædia of Medicine," nor have I been able to find record of it in any of the journals. Sudden great rise in temperature, feeble pulse, tender abdomen, and symptoms of prostration occurring in a convalescent typhoid patient, would warrant the supposition either of a relapse, a perforation of the intestine with peritonitis, or some pulmonary inflammation. Of course minute differentiation of the attendant symptoms, with careful examination of the patient's abdomen and chest, would put one on the right track. This case demonstrates the value of these examinations and also of careful attention to the state of the bowels. The causes of the constipation were a natural sluggishness of the intestines and the use of milk[*] diet. If the impaction had occurred higher up in the bowel and at a time when Peyer's patches were ulcerated and had not cicatrized, death from perforation or hemorrhage would have been almost inevitable. In fact, Wilks[†] mentions a case where death occurred during the third week from perforation due to obstinate constipation; and Hudson[‡] describes a similar one, in which there was profuse hemorrhage. So also Murchison,[§] who makes record of a death in typhoid fever from perforation and peritonitis on the forty-second day, preceded by prolonged constipation. The hyperpyrexia in the case under consideration was due no doubt to reflex irritation, and the prostration, to the exhausting and unavailing attempts at defecation.

The treatment necessarily consists in a prevention or removal of the cause. This is best done by the administration of a teaspoonful of castor-oil every third or fourth day when the bowels become confined, or by the use of simple enemata. Under no condition, however, should any of the drastic purgatives be given.

The tendency to produce constipation during convalescence is almost the only disadvantage of an exclusively milk diet; it may be usually overcome by allowing the patient from six to twelve fluid ounces of beef-tea during the day in addition to the milk.

CASE VI.—*Typhoid fever—Complete obstipation from paralysis of large intestine.*—A. A. S——, aged twenty years, bartender, of ordinarily temperate habits, was admitted to the men's medical ward on December 17, 1879. Throughout his life he had been subject to attacks of epistaxis, but nevertheless considered himself healthy; he had rubeola in 1874. His friends gave December 13th as the date of the onset of the fever, as this was the day on which he was obliged to give up work. The symptoms were rigors, a sense of great muscular weakness, headache, epistaxis, heat of skin, anorexia, vomiting, and a sluggishness of the bowels. From December 13th until his admission to the hospital he rather fought against his illness, was very imperfectly cared for, and was given one or more purgative pills, which acted inordinately.

When admitted his condition was very grave. He was greatly prostrated, had evidently lost much flesh, his face was dusky and expressionless, and there was hebetude and subsultus tendinum. His tongue was red and clean at the edges and tip, while the centre was covered with a dry, brown, fissured coating; it was protruded slowly and was tremulous. His lips and teeth were covered with sordes, his pharynx was reddened, food was taken with reluctance, and there was occasional vomiting. His abdomen was tympanitic, there was tenderness in the epigastrium and gurgling in the right iliac region, and the area of splenic dulness was extended; the bowels had been confined for twenty-four hours. Fifteen or twenty characteristic rose spots were counted on the abdomen and anterior suface of the chest. There was retention of urine, and a specimen removed by the catheter was found to be clear, high-colored, acid in reaction, 1.026 in specific gravity, to contain an abundance of urates, and a quantity of albumen equal to nearly one-fourth of the bulk tested; no casts could be discovered by the microscope. The axillary temperature at 6 P.M. was 104.5°, the pulse 116 and very weak. During the night there was muttering delirium.

On December 18th his general condition was unchanged; he vomited several times, the ejecta consisting of curdled milk and mucus tinged with bile; the epigastric tenderness continued, and when roused he complained of pain in this position; he could be induced to take but little food, on account of a constant sensation of fulness of the stomach. The constipation and retention of urine continued. A profuse epistaxis began at 11 A.M. and lasted for an hour and a half. The temperature at 6 A.M. was 101.5°, at 6 P.M. 104°; the pulse at the same hours was 100 and 120, and was very compressible.

On December 19th the hebetude was less decided and the face had a better color. There was more vomiting, a few dark-colored clots of blood being rejected; the epigastric tenderness and pain remained. There was no evacuation from the bowels, and the urine had to be withdrawn by a catheter, and showed no diminution in the amount of albumen. Temperature: morning, 101.6°; evening, 103.5°; pulse, 116, somewhat stronger; respirations, 37, shallow.

On December 20th the hebetude was again very marked, and the face was more dusky and expressionless than on any of the previous days. The constipation and retention of urine persisted. The abdominal distention was noticed to be somewhat irregular, the outline of the colon being indistinctly traceable. At 4 P.M. and at 8 P.M. he vomited a large quantity of red, clotted blood. Temperature, 101° to 103°; pulse, 100 to 120, after the hæmatemesis it was very feeble. At 6 A.M. on December 21st the temperature was 103°, the pulse was imperceptible in the radial arteries, and the patient had passed into a state of coma. There was a slight discharge of blood from the anus. Death occurred about two hours later.

[*] Stillé and Maisch's Dispensatory, Philadelphia, 1879, p. 792.

[†] Guy's Hospital Reports, third series, 1855.

[‡] Lectures on the Study of Fevers, Dublin, 1867, p. 290.

[§] Op. cit , p. 575.

During the short period that the case was in the hospital every effort was made to maintain the strength by the administration of liquid nourishment, and of stimulants in the form of alcohol, carbonate of ammonium, and digitalis. Twenty grains of quinia were given in four doses between seven and eight o'clock in the evening of each day. Hypodermic injections of gr. ¼ to gr. ⅛ of sulphate of morphia were employed with moderate success to induce sleep, and enemata repeatedly given without any effect upon the constipation. A hypodermic injection of ♏ x. of the fluid extract of ergot quickly arrested the epistaxis of December 18th, after the application of ice, of powdered alum, and the injection of hot water up the nostrils, had failed; but the same procedure seemed to have little influence upon the hæmatemesis which occurred later. Attempts were made to lessen the epigastric pain by mustard plasters and flaxseed poultices.

At the *autopsy* the *colon* was found to be altered in position, the transverse portion of the gut being curved downward nearly to the pelvis, overlaying and concealing the small intestine. From the ileocæcal valve to the sigmoid flexure the large gut was dilated, its diameter being increased at least one-half. This distended portion was filled with dark-colored, coagulated blood, and its mucous membrane was thickened and dusky red in color, the redness ending abruptly at the lower extremity of the dilatation. In the cæcum and ascending colon there were, in addition to the intense congestion, a number of superficial follicular ulcers. The *sigmoid flexure* and *rectum* were empty, quite contracted, and without alterations in their mucous surfaces. The *small intestine* was nearly empty, and the mucous membrane in the duodenum and jejunum was normal; in the ileum it was injected, and the Peyer's patches were ulcerated, these characters becoming more and more marked as the ileo-cæcal valve was approached. The *stomach* was empty, its mucous membrane presented the changes observed in chronic catarrhal conditions, and scattered over its surface were a few ecchymotic patches, none of which were larger than the head of an ordinary pin. The *spleen* was about four times the usual size, and was engorged with blood. The other viscera presented no important alterations.

Constipation due to paralysis of the large intestine is quite a rare complication of typhoid fever. With this there was also in this patient retention of urine, caused by paralysis of the coats of the bladder. The varieties of paralysis that occur most frequently during the febrile stages of this disease are involuntary evacuations of the bladder and rectum (paralysis of the sphincters of the anus and neck of the bladder), inability to protrude the tongue, dysphagia, inarticulate speech, and lack of power to close the eyelids. Those which happen in the post-febrile stage[*] take the form either of paraplegia, hemiplegia, strabismus, paralysis of the facial or of other individual nerve. Temporary aphasia[†] has also been reported to have occurred.

In connection with this case, Dr. Starr stated that it was the first instance that had ever come under his notice where obstipation from paralysis of the bowel existed as a complication of typhoid fever. In his opinion the paralysis was due to the intense inflammation of the coats of the gut, the inflammation having undoubtedly been set up by the active and ill-advised purgation of the early days of the illness, before entering the hospital. He considered the case of great interest, also, because it illustrated the fact that paralysis of a segment of intestine is capable of presenting an obstruction quite as impassable to the intestinal contents as an invagination or stricture.

Case VII.—*Typhoid fever complicated by an eruption of taches bleuâtres, and followed by cystitis.*—James C——, aged twenty-four years, weaver by occupation, was admitted to the men's medical ward, December 24, 1879, very ill and prostrated. He stated that he had had variola ten years previous, but with this exception had enjoyed good health until the present attack. It commenced on December 10th, with headache, malaise, muscular soreness, anorexia, abdominal pains, and diarrhœa, which had so weakened him that he was incapacitated for work, and took to his bed one week before his admission to the hospital. At this time he was pale and drowsy, the skin was hot and dry, the pulse was frequent and feeble; the bowels were loose (six watery passages daily), the belly distended, and there was pain and gurgling on pressing over the cæcum. The tongue was dry and coated, protruded with difficulty, its edges trembling; organs of respiration healthy; urine normal. Over the belly was a characteristic eruption of rose-colored spots, and in addition a number of light bluish spots, the "taches bleuâtres" of French writers. These were also noticeable on the inside of the thighs and forearms. They were of an irregularly rounded form, one-fifth to one-third inch in diameter, not elevated, not affected by pressure, and most noticeable by candle-light.

At 6 P.M. on the evening of the day of admission his axillary temperature was 103°; pulse 94. He slept very little during the night; was restless, but not delirious.

On December 25th the morning temperature was 100°; pulse 80, feeble. He was put on liquid diet, with twelve ounces of milk-punch (1 to 2), and a mixture of 3 gr. quiniæ sulph. with 10 gtt. ac. muriat. dil., every four hours. Moderate doses of ammonii carb. and tr. digitalis were administered when the pulse indicated their use, and hypodermic injections of morph. sulph., ¼ gr., were ordered p. r. n. Pain over the abdomen was so great that a flaxseed-meal poultice was applied.

The fever pursued a course of moderate severity; the diarrhœa subsided, the heart's action improved so that the ammonii carb. and tr. digit. were soon discontinued. The temperature during the second week fluctuated between 102.5° in the evening and 100° in the morning, the pulse at the corresponding times being 100 and 88.

On December 29th retention of urine occurred, which persisted for six days and required the use of a catheter three times daily. Sleeplessness was the only other unfavorable symptom present, but was readily overcome by the use of morph. sulph

On December 31st, the commencement of the third week of the fever, the symptoms began to amend. The tongue became more moist, was protruded with ease, and its coating, as well as the sordes around the teeth, gradually disappeared. The typhoid eruption had faded away, and the blue spots above noted were not visible on the forearms, while those on the abdomen and thighs were lighter in hue. The pulse had become feeble, but was soon strengthened in force and fulness by an increase to fifteen ounces of the milk-punch. The axillary temperature did not run to a higher point than 102° in the evening and fell to 100° in the morning; pulse: evening, 96; morning, 84. The bowels were inclined to constipation, but the occasional use of enemata provoked easy passages, natural in consistence and color. Toward the end of the week the temperature began to make marked remissions, and by January 6th, the close of the third week, it had fallen to the normal line both in the evening and morning.

---

[*] Deutsches Archiv für klin. Med., 1872, ix., p. 480.

[†] Gaz. hebdom., 1865, p. 140–591.

All the symptoms indicated a rapid convalescence. There was no pain in the abdomen, the organs of circulation and respiration were healthy, the urine was voided spontaneously, bowels regular, sleep natural, and the patient, though emaciated and weak, felt well and was hungry.

On January 8th the diet was cautiously increased and consisted of milk, beef-tea, chicken-broth, two soft-boiled eggs, farina and soft bread; the milk-punch was reduced to twelve ounces, and in a few more days to six ounces.

On January 11th, however, the patient complained for the first time of tenderness over the bladder, with burning pain during urination, and from this time until the 24th suffered severely from cystitis.

On January 28th he sat up for the first time, and though weak, was able to walk to the end of the ward to be weighed. His weight was 123 lbs. There were present no unpleasant symptoms, except loss of flesh and weakness. He was put on a mixture of iron, quinine, and strychnia three times daily. From this time he made decided and rapid improvement, and by February 17th, the date of his discharge, he weighed 144 lbs. and felt perfectly able to resume his work.

The presence of "taches bleuâtres," retention of urine, and cystitis, are the features of interest in the clinical history of the above case. The first have been occasionally observed in typhoid fever, and also in simple continued* fever, and they hence do not constitute a specific characteristic of either. They are apt to confuse the physician and lead him to suppose the eruption to be that of typhus fever, or that the two diseases—typhus and typhoid—co-exist. In typhus fever, however, the spots are first pinkish or florid in hue, and disappear by pressure; subsequently they become reddish brown or livid, according to the amount of pigment, and do not disappear on pressure. The "taches bleuâtres" do not pass through these successive stages, but are always of a uniform delicate bluish tint; they are not elevated above the skin, are of an irregularly rounded form, and are not affected by pressure. Trousseau† described them and made the observation that, when present, the case generally ran a mild course.

Retention of urine has been noted by Murchison in 2 out of 100 cases, and was present in two of the cases here recorded. It does not occur so frequently as in typhus fever, and is due, most probably, to paralysis of the coats of the bladder. Neglect to daily examine the hypogastric region by palpation and percussion, and to question the patient concerning his urine, may lead to serious results, such as convulsions, catarrh, or ulceration of the bladder. It also must not be forgotten that incontinence may coexist with retention—the "incontinence of retention" of some writers, the urine dribbling away from a distended bladder.

Cystitis, like other catarrhal affections of the mucous membranes, is not a very uncommon sequel of typhoid fever. Its symptoms are so marked that it can scarce fail to be early recognized, and it generally yields to judicious treatment. Its direct causes are unknown, but retention of urine and the constant use of quinine* may be cited as elements in its production.

A CASE OF EPILEPSY

Depending Probably upon Hypertrophic Cervical Pachymeningitis.

By HORATIO R. BIGELOW, M.D.,
WASHINGTON, D. C.

The above hypothesis is, possibly, more absolute than it should be. The patient is still living, so that a diagnosis, while it may wear the semblance of probability, cannot be confirmed by actual demonstration. It is sufficiently interesting, however, to warrant publication, as it seems to be confirmatory of the views of Charcot, as given by him in his "Leçons sur les Maladies du Système Nerveux." The word "epilepsy" in this connection does not convey precisely the meaning intended, but for want of a better nomenclature I use it as indicative of a train of symptoms constituting an "epileptic condition." The minutest inquiries from the patient and from the father failed to elicit any history of syphilis, although there had been suspicious symptoms in the grandfather.

About twelve months ago I was called to see F. H——, a young man, twenty-three years old, of bilious habit. I found him lying upon the floor with an epileptic seizure. The father is a hale, hearty man, fifty-five years old, somewhat eccentric in conversation. The mother is a few years younger, thin, angular, and sallow, and an ardent spiritualist. There are two daughters of this parentage, the younger of whom is chlorotic in a marked degree. The elder is, seemingly, in perfect health.

Early History.—From infancy my patient had suffered with similar attacks, coming on periodically. For many years they appeared every four months, but latterly they manifest themselves oftener—every three months perhaps. They have never supervened upon the ingestion of a full meal, neither have they been preceded by any "especial aura." His first remembrance of any precursory symptom was that of a whirling and dizziness in his head. Latterly he has suffered with loss of muscular power in the arms, and with erratic "rheumatic pains" of so severe a nature that he often cries out. He has no will-power over the arms, which jerk about in all directions.

Condition at time of Examination.—He is of medium height, dark hair and eyes, and with a peculiarly vacant, wandering look. His conversation is childish—as from arrested cerebral development. He has but little power of mental concentration, although he does not lose the thread of the discourse. There is no aphasia or agraphia, neither is his speech faltering. He delights more in the things belonging to childhood than in the mature discussion of ideas appertaining to manhood. His gait is uncertain and tottering, which, he says, has come upon him lately. The power of pressure in both hands is so small as to be almost unappreciable. The protruded tongue shows no deviation to the right or left, and there is no loss of symmetry in the face. His sight is bad—worse at some times than at others. He complains of much pain all around the head, at times most severe over the eyebrows, and at other times over the occiput. He has "numbness" in the arms, with sharp, wandering pains. The heart and lungs are both healthy, and his digestion pretty good. Of late his parents have noticed a loss of memory, chiefly of recent and present events. His urine is normal. There is no responsive muscular excitability to the faradic current. The hands and feet are cold and colorless, with much muscular wasting. His fingers not responding, he is unable to write well. The "patella tendon reflex" responds at about .12 interval. He has electric sensations in various parts of the body. In the left axilla the temperature is 100°; in the right, 101°; in the rectum, 101.5°. In the right parietal region it is 101.2°; in the left parietal, 99.9°; over the occiput it is 101°. which temperature remains as far down as the last cervical vertebra, when it commences to fall slightly. There is no tenderness upon pressure along the spine. The pupils are contracted.

Such, in brief, were the points of diagnosis which I had for guidance. Upon my first visit I confess that I was puzzled to make out either cause or localization, and so administered a gentle placebo, bromide of potassium I think, and returned to my office to study and to think. The salient features in the case were:

1. Contraction of the pupils.
2. The peculiar gait.
3. The condition of the muscles, wasting, loss of electric irritability, loss of pressure power.
4. The periodicity of the attacks.
5. The peculiar and painful sensations of the patient.
6. The temperature.
7. The absence of essential paralysis.

All of these symptoms accompany intra-rachidian tumors, vertebral cancer, thrombosis with softening, gummata, and Pott's disease. The periodicity of the attacks, together with the youth of the patient and the absence of a syphilitic history, would seem to render the presence of pachymeningitis improbable. But while Charcot admits that periodical seizures in this disease are rare, and not at all characteristic, he has met with five cases in which they occurred. The age of the patient excluded the existence of *senile* arterial degeneration, but such degeneration *occasionally* exists in the young. The muscular condition indicated a pressure upon the interior roots of nerves—pachymeningitis? But these same muscular phenomena also occur in meningo-myelitis. This latter disease being very usually of syphilitic origin. My patient, so far as I could learn, had not had inherited or acquired syphilis. Reasoning by exclusion chiefly, I formed the conclusion that it was either a case of cervical pachymeningitis or of meningo-myelitis with which I had to deal. It must be remembered, however, that there was *no* tenderness along the spinal column, no dysphagia or difficulty of breathing, no marked sensation accompanying the application of heat and cold along the spine, no sexual derangement, no parasthesia, and no sense of constriction. The muscular conditions common to both of these diseases were present, and in either case might be caused by compression of the cord. The contraction of the pupils pointed to a lesion in the upper part of the cord.

The next day I called at the house and applied the actual cautery at three different points in the upper cervical region, and ordered pills of the iodide of iron and ergot. I also advised daily shampooing of the affected muscles, salt baths every morning, the body to be well rubbed with a crash towel afterward. The blisters made by the cautery I kept open, applying to them an ointment of the iodide of calcium. For three months there was no appreciable change in the condition of the patient, although the disease did not seem to be progressive. The pains were quieted with full doses of the bromide of potassium. As time went on, however, and the treatment was persisted in, there was considerable return of power to the hands, the pains became less severe, and the sight was somewhat improved. During the past twelve months he has had but one epileptic seizure, and his gait is much better, although still uncertain. His mental powers are unaltered. The disease seems to be held in abeyance. The swelling and thickening of the cord, should such a condition really exist, chronic in nature, manifests no tendency to increase, but judging from the improved action of the anterior roots of nerves, the inference is a proper one that the pressure is becoming less. This pressure was not due to inflammatory products, as I believe, for such products always manifest a tendency to increase in severity, unless they happen to be of a specific nature, and then, if the case be seen early enough, they will disappear under specific treatment. The temperature which was so unequal and interesting when I was first called in, has greatly improved and is normal everywhere, save at the occiput, where it is very slightly elevated.

◆

A CASE OF

EXTRACTION OF A FOREIGN BODY FROM THE VITREOUS CHAMBER,

WITH RETENTION OF USEFUL VISION IN THE INJURED EYE.

By HENRY S. OPPENHEIMER, M.D.,
RESIDENT SURGEON NEW YORK EYE AND EAR INFIRMARY.

L. R——, a healthy smith, aged nineteen years, came to me on July 2, 1880, with the request to have his eye looked at. He said, three days before, while striking one hammer with another, he felt something fly into his right eye. He had no pain or other inconvenience from it, and had been at work, as usual, but concluded to come to the infirmary "to be sure that it was all right," as he expressed himself.

On examination, I found, immediately below the limbus, down and inward, a slight elevation above the sclera of a minute nodule of tissue, consisting of the conjunctiva and underlying tissues. Expecting to find the foreign body imbedded there, I lifted this up with a needle and found instead an opening through the sclerotic. The front of the eye appeared otherwise perfectly normal. The ophthalmoscope showed a faint opacity in the vitreous. A few drops of an atropine solution soon dilated the pupil widely. During this process of dilatation a few drops of blood made their appearance in the anterior chamber. Through the enlarged pupil could be seen two or three red streaks (blood) in the vitreous extending from the region of the wound out, up, and backward. No foreign body could be seen. I informed the patient that the piece of steel was in his eye; that either it or the eye had to be removed, and that I should try to extract the former with a magnet. He consented at once. Dr. Emil Gruening very kindly lent me the magnet devised by himself for this special purpose, and I am also indebted to him for his kind assistance and moral support during the operation. The patient was etherized, and it was noticed that during this process the anterior chamber filled with blood. The eye was adducted at maximum, and an incision was made as far back as practicable, on a level with the lower border of the rectus externus. This incision was carried to the sclera, and from this time the overlying tissue were well dissected back over a space the size of a small lozenge. When all bleeding had stopped, I carried a lance-knife, about 4 mm. in width, into the vitreous chamber the whole length of its blade.

I then introduced the magnet, revolving it carefully, and, after a time, removing it slowly. Nothing came with it. A powerful magnet was then held to the edge of the wound without evident effect. These movements were repeated three times, the magnet being revolved each time in a different portion of the vitreous chamber. Great care was taken to avoid the lens and the fundus. After the third withdrawal the foreign body appeared in the wound, and was withdrawn by the magnet. The lips of the wound had not been held apart, and probably the foreign body (which proved to be a scale of iron about a grain in weight) was stripped from the magnet on its exit through the wound. *Not a particle of vitreous was lost.*

The conjunctiva was united over the wound by three sutures. Union per primam occurred. Immediately after the operation the anterior chamber was densely black, so full was it with blood, and it remained in this condition for over three weeks. When the blood was finally absorbed, a dense, dark greenish deposit could be noticed on the posterior surface of the cornea. This has gradually disappeared since then from the periphery, but can still be seen over the centre of the cornea, although even there it has become much thinner, and is evidently being absorbed slowly. The patient suffered no pain during the healing process. On September 1st, two months after the operation, he was permitted to resume work. His condition was then as follows: Conjunctiva and sclera normal; cornea clear, excepting the thin central opacity above mentioned. Iris normal in color and easily dilatable with atropine, but recovers its normal contraction somewhat readily. Lens clear; on its anterior capsule a fine, thread-like stellate marking can be traced. Vitreous filled with dark stripes. Details of fundus cannot be made out clearly. Tension normal. Vision=20/C on clear days (V. L. E.=20/xx). Field contracted somewhat in all directions, but markedly so upward and inward. The interesting points in this case to me are:

First.—The demonstration of the usefulness of the *magnet* in similar cases. Before its application in ophthalmic surgery the foreign body, as it could not be seen, would therefore either have been left in the eye—a source of permanent danger to it and its fellow—or the eye would have been enucleated. Attempt at extraction of a foreign body which could not be seen out of the vitreous chamber without a magnet would not have been thought of.

Second.—The bleeding into the anterior chamber began only after the instillation of the atropine and seriously precipitated by the administration of ether. This hemorrhage seems to have been from the wound in Fontana's space, or the extreme periphery of the iris. The scale seems to have passed through this region and through the zonula without touching the lens.

Third.—The peculiar deposit on Decemet's membrane, which remained so persistently. The coloring matter of it must have been deposited from the blood, but very probably some plastic material was united with this, else the absorption must have gone on much more rapidly.

Fourth.—The dense masses of blood in the vitreous absorbing so very slowly, as they usually do, go to strengthen the opinion generally held that the introduction into the vitreous of instruments is, at best, a matter of very serious moment, and should not be resorted to lightly.

Fifth.—The limited field, to all but light perception, seems to me to indicate the probability of changes in the peripheral portions of the choroid, thus interfering with the nutrition of the lens. The slight marking on the anterior capsule could not have been caused either by the foreign body or the manipulations. The prognosis for a further improvement in vision within the field seems to be good.

Reports of Hospitals.

HOSPITAL OF UNIVERSITY OF PENNSYLVANIA.

CASE OF DOUBLE ANEURISM OF AORTA AND DESCRIPTION OF TREATMENT OF INTERNAL ANEURISMS BY ELECTROLYSIS.

By WILLIAM PEPPER, M.D.,

PROFESSOR OF CLINICAL MEDICINE IN THE UNIVERSITY OF PENNSYLVANIA.

GENTLEMEN: I show you first, this morning, the specimen from a case of a very interesting character—a case, in fact, of double aneurism of the aorta; and I propose to discuss with you, for a few moments, the subject of electrolysis with reference to the relief and cure of aneurism. The man from whom this specimen was taken was always a hard-working man, plying an occupation which required a great deal of muscular exertion, and who also showed a distinct syphilitic history. He first came under treatment for supposed intercostal neuralgia, but the pain remained so constant and severe that a more thorough examination was given, and a prominence at the spine in the thoracic region was discovered, whose pulsating and heaving character, and whose thrill warranted the diagnosis of aneurism. To make sure it was no other form of thoracic tumor, the exploring-needle was used to confirm the diagnosis.

At this point let us discuss the treatment of internal aneurisms. As they are internal and not in reach of the surgeon, so that the main arterial trunk may be ligated, the following medical means have been thought of:

First.—Specific remedies, and those that will favor clotting of blood, as the mineral salts, lead, etc.

Second.—Physicians, finding that as people were starved the blood became very rich in fibrin, thought that there was more likelihood of a clot being formed under a plan of partial starvation than when the patient was allowed full diet.

Third.—As all increased muscular exertion causes increased action of the heart, and hence, the more immediate danger of rupture by the increased force of the blood-current through the sac, rest was considered beneficial.

In reality, the last two, namely, perfect rest and as low diet as is consistent with absolute life, are the most important elements in our medical treatment; and, as you never find aneurisms without atheromatous changes in the coats of the arteries, alterative remedies, as potassium iodide, become valuable, more especially when syphilis is an element in the disease.

In the case before us, potassium iodide did not check the progress of the affection.

But supposing, despite the treatment referred to, the aneurism goes on growing larger and larger, protruding more and more against the chest, so that the thoracic walls and ribs are giving way before it, the tissues over it are growing thinner, and the thrill and pulsation more evident each day, the question will then come up, and is often anxiously asked by the patient, "Can nothing else be done to relieve me, to ward off this impending result, and save the life just hanging by a thread?"

This is often very difficult to answer, except when the aneurism is of a vessel so located that the main trunk can be ligated; but of course, when situated in the thoracic aorta, or arch of the aorta, this cannot be done.

There remains, then, nothing to do but to put something into the sac that mechanically will form a clot in it. Needles, horse-hair, threads, etc., have been tried with little advantage. The galvanic current alone has proved a success.

You know that if two needles, connected with the poles of a battery, be placed in a dish of albumen, it will be soon coagulated. I take here two needles so connected, and by placing them into this white of egg you see immediately the needles become coated; and as I continue the process, a firm, strong clot is formed at the negative pole, and a small, friable one at the positive pole. This process has been taken into consideration in the operation of electrolysis.

The mode of operating is very simple. You need two sharp platinum needles, coated with gutta percha, and after freezing the skin with ice or with ether-spray, you should plunge one needle, previously connected with the galvanic battery, boldly in with a single stroke, until you feel all resistance cease. The second needle is to be introduced in the same way.

Thus far it will cause but little pain, but the moment the current is turned on the heart will give a great bound and the pulse become greatly accelerated. This should not, however, be any cause for alarm.

Gradually turn on the full current and leave it on for some minutes, when the operation is completed by withdrawing your needles.

Electrolysis is only appliable when the medical treatment has been tried, and when the aneurism comes up close to the thoracic walls; but this is so often the case, that it can be frequently applied.

Here is a specimen from a case in which the operation had been performed twice in this hospital, at the urgent request of the patient.

The needles were introduced, and almost immediately were followed by great relief of pain and great reduction of pulsation and thrill.

In a short time, however, all these bad symptoms returned, and the operation was repeated, with the same beneficial results. The man finally died from exhaustion, and at a post-mortem examination large fibrous clots were found at the points of insertion of the needles, which no doubt prevented rupture of the sac. The operation was therefore perfectly satisfactory, so far as relief of pain and comfort are concerned.

The last fact is the same as is shown by the study of the result of about one hundred cases, in whom, in about two-thirds of them, temporary relief from pain and suffering was given, and in only a very small per cent. had it a curative effect; still, in no case had it ever done any harm. I think, myself, that the operation under such circumstances as I have stated is perfectly justifiable, and I would be perfectly willing to have it performed upon myself.

To return to our first patient, I would say that he came into the hospital for such treatment; but the day before yesterday, while standing at his bedside, he commenced spitting blood, and in less than two hours he was dead.

In looking at the aorta, it shows disease of the coats of the descending portion, and a double aneurism: a small one coming from the descending arch, about the size of a walnut, unruptured, and one ruptured sac, as large as a child's head, springing from the posterior wall of the thoracic portion. This large sac had hollowed out the surrounding lung, and in bursting had torn the adjacent structures and opened a bronchial tube. Of course, in this case the process had gone on so long that the operation of electrolysis would have been perfectly negative in its results, and, as upon it might have rested the blame of this unfavorable termination, I am glad it was not performed.

PRESBYTERIAN HOSPITAL, NEW YORK.

TRANSPOSITION OF VISCERA.

SERVICE OF DR. GEO. F. SHRADY.

Reported by J. W. STICKLER, M.D., House Surgeon.

H. TIPP, aged twenty-seven years; single; farmer; native of United States, enjoyed good health until two years ago, when he had an attack of cystitis. For the treatment of this disease he entered the Presbyterian Hospital, in the service of Dr. Geo. F. Shrady, attending surgeon.

A physical examination revealed the following remarkable deviations from the normal positions of the viscera of the thorax and abdomen. Heart: apex-beat directly under the right nipple; impulse and rhythm normal; no valvular murmurs. Surface measurements: vertical—from the second intercostal space to the fifth rib, 4¾ inches; from the median line to the right on the third rib, 3 inches; on the fourth rib, 4 inches; on the fifth rib, 4½ inches. Liver occupied the left hypochondrium and part of the epigastrium. Its vertical measurements were, so far as could be ascertained by auscultatory percussion: on the left of the median line in front, 3½ inches; on a line with the left nipple, 2½ inches; in the axillary line, 2½ inches; posteriorly in the dorsal region, 2¼ inches. Spleen was behind the ninth, tenth, and eleventh ribs, on the right side in the axillary line, and measured, in length, 4 inches; in breadth, 2½ inches.

While listening to the patient swallow, it was found that the œsophagus passed down in front of the spine to about the fifth dorsal vertebræ, at which point it was deflected toward the cardiac orifice of the stomach in its abnormal position. The position of the stomach was ascertained by performing percussion in the epigastric region after giving the patient a seidlitz powder. The area of tympanitic resonance corresponding to the cardiac end of the stomach was on the right side, while the resonance diminished toward the left extremity of the viscus. The right testicle was the lower of the two. The rectum passed from the right side of the sacrum to its left side.

Patient says he has never had an inflammation of the pleura, lungs, pericardium, or peritoneum, and a careful physical examination would confirm the statement. His present excellent health, fortunately for him, will preclude the possibility of verifying the diagnosis in the manner usual with such interesting cases.

Progress of Medical Science.

Experimental Study of the Valvular Lesions of the Heart.—By means of a sound passed through the carotid artery of an animal, Dr. Otchakowsky produced perforation or entire separation of one or more aortic valves. As the result of this artificial valvular insufficiency the blood-pressure in the arterial system was very much lowered in proportion to the degree of the valvular defect. This effect was most marked at first, gradually subsiding, and entirely disappearing in five or six weeks. If the animal was killed at that time, hypertrophy and dilatation of the left ventricle were always present; these two conditions were always associated, the hypertrophy being more prominent at first, and the dilatation later on. All the abdominal organs were found congested, the liver the most, and the kidney the least; the congestion was in inverse proportion to the length of valvular lesion, except in the case of the liver, which always contained an abnormally large amount of blood.—*Vratch*, 1880, No. 12.

Influence of Alcoholic Baths on the Perspiratory Function of the Skin.—Dr. S. Wassilieff found that, after the skin had been thoroughly rubbed with alcohol, hot baths induced much more profuse perspiration, exceeding sometimes four and five times the amount of water lost without previous treatment with alcohol. Hence, the two processes should always be combined when there is indication for extraction of a considerable quantity of water through the skin. Dr. W. explains the action of alcohol by an rritation of the sensitive, and, perhaps, also of the secretory nerves of the skin, and also by the removal of fat from the surface of the skin and the glandular pores.—*Vratch*, 1880, No. 13.

Two Consecutive Lithotomies on a Boy.—Dr. Orloff removed a stone weighing one ounce, by the ateral method, from a boy twelve years old, and another stone weighing 100 grains, by suprapubic operation, eighteen months later. The wounds in he latter case healed in nineteen days.—*Meditz. Obozrenie*, p. 726, May, 1880.

Alkaline Treatment of Cancer.—Dr. Reier exhibited to the St. Petersburg Medical Society, three patients who had been treated in the above manner, as proposed by Dr. Busch. It consisted in scraping off all cancerous tissue, and in the systematic use of a saturated solution of soda. The first patient was ixty years old. On the left side there was an absence of the eye, orbit, superior maxilla, also hard palate and greater part of the nose. Five weeks before, hese parts presented cancerous infiltration with a endency to rapid extension and ulceration. When exhibited, the surface presented healthy granulations nd cicatrization was already beginning at the anle of the mouth. The second case was also an old man. Destruction less extensive. Healing more advanced. Surface granulating, and general peripheral cicatrization. Third case was a woman nearly ninety years old, cured. Former seat of cancerous growth showed a cicatrix of a uniformly solid appearance. The growth was examined microscopically six months ago, and had every feature of a malignant tumor. This treatment is based upon the power of strong alkali to dissolve the cellular elements.—*Vratch*, 1880, No. 23.

Continuous Intra-uterine Antiseptic Irrigation in Septic Puerperal Diseases.—This method, proposed by Dr. Schücking in 1877, was very favorably received by all the prominent obstetricians in Europe, and its use is rapidly increasing. In Russia, it has been but little used, and Dr. Levenstein has sought it this paper to bring it to the favorable notice of his compatriots. He uses an ordinary black rubber tubing fastened by tapes to the belt. The irrigating fluid is the dilute tar-water (1–20), but other antiseptics can be employed—salicylate of soda (1–250), chlorate of potassium (1–200), chlorinated lime (1–350), carbolic acid (1–100), etc. The temperature of the fluid in the febrile conditions is lower, in apyrexia higher, the subjective feelings of the patient being always considered. The fluid enters the uterus drop by drop, and escapes per vaginam through a hole cut in the mattress into a receptacle under the bed. Irrigation is kept up continuously during the entire sickness, two to eight and sometimes eleven days. It is borne very well by the patients and does not cause any inconvenience whatever. The cases where this treatment is indicated are various septic processes following labor: purulent, croupous, and diphtheritic endometritis, acute para- and perimetritis, and particularly pyæmic metro-phlebitis. In the course of three months Dr. L. treated 41 such cases, with only 34 per cent. of mortality, while the usual death-rate in his institution had been 50 to 57 per cent. Of these 41 patients, 16 were treated in November; 14 recovered. They were mainly cases of septic endometritis, frequently complicated with para- and perimetritis, but several were cases of pyæmic metro-phlebo-thromboses; some of the cases were very severe, presenting as many as nine rigors, and a temperature as high as 41°. During December, the cases of diphtheritic endometritis made their appearance, frequently complicated with general peritonitis. Usual death-rate, according to Winkle, is 65 per cent. for this disease. Eleven patients were treated during this month; 7 recovered. In January diphtheritic endometritis became still more common, and the malignity of the epidemic reached its maximum. Seven cases appeared in one ward, all attended by the same nurse. Fourteen cases were treated by irrigation, of which 6 recovered. All cases, with the exception of those of diphtheritic endometritis, were treated exclusively by irrigation, the latter also by special treatment peculiar to this disease. Constant irrigation of uterus is recommended not only as the treatment for these diseases, but also as a prophylactic measure.—*Vratch*, 1880, No. 25.

Effects of Electric Light on the Accommodation.—Very extensive experiments with Jablakoff's candle lead Dr. Liubinsky to the conclusion that electric light, by its brilliancy it has the same effect on accommodation as an insufficient light, namely, producing temporary myopia. As the light is never absolutely even, the changes in its intensity produce a very fatiguing effect on the eye, as with the variations of light accommodation has to be constantly readjusted.—*Vratch*, 1880, No. 26.

Experimental Contributions to the Question of Spontaneous Hypertrophy and Dilatation of the Heart.—To determine the extent of the etiological importance of increased cardiac activity in the formation of hypertrophies and dilatation of the heart, Dr. Zassietzky undertook the following experiments: He selected four male kittens belonging to the same litter, and after they had grown up two of them were chased daily for one-half to two hours. At the end of six months all were killed and their organs examined. He found that the hearts of the chased kittens presented some peculiarities indicating that essential structural changes occurred as the result of the experimental conditions. They were longer, a trifle wider, but weighed less; the thickness of the right ventricles and auricles was greater, but the walls of the left ventricles and auricles were thinner. The aorta at its junction with the heart was wider; no difference was observed in the pulmonary arteries. The muscular fibres of the left side of the heart were less wide, while those of the right side were thicker. The lungs, spleen, and brain were found to weigh less. No difference in the other organs.

These changes were explained by an earlier occurrence of hypertrophy and subsequent atrophy and dilatation on the left side of the heart, than on the right, so that at the time of *post-mortem* examination the first had entered already the stage of atrophic preponderance, while the second bore still all the signs of hypertrophy.—*Vratch*, 1880, No. 28.

On the Reunion of Isolated Pieces of Long Bones.—Dr. Jakimowitch states that thin pieces of long bones entirely separated from periosteum and marrow can again be reunited with the adjoining parts.—*Vratch*, 1880, No. 29.

Treatment of Bromide Rash by Salicylic Acid.—Mr. Prowse, of Cambridge, says that salicylic acid, applied locally, is a very effective and certain remedy for the pustules and peculiar ulcerations that are caused by the prolonged use of bromide of potassium. He uses a saturated solution of the acid (one grain to the ounce of water) and applies it frequently, and where possible, constantly by means of lint and oiled silk. He states that he has seen sores as large as the palm of the hand, due to the bromide, heal soundly in less than seven days under the use of this lotion.—*British Med. Jour.*, July 24th.

The Arciform Fibres of the Medulla Oblongata.—M. Luys has made an interesting communication to the *Société de biologie* on the subject of the connections of the arciform fibres of the medulla oblongata. He maintains that they are nothing more than the terminations of the inferior cerebellar peduncles. After these have reached the lateral parts of the medulla, the fibres pass obliquely into this region and increase its size by passing between the ascending fasciculi from the spinal cord. Some of the fibres, however, pass into the interior of the medulla, and these are the concentric fibres which form so conspicuous a feature in all transverse sections of the medulla. That part of the fibres which apparently remains on the external surface of the medulla, and extends on the restiform bodies and anterior pyramids, presents great variations in direction and terminal distribution. Some of the fibres surround the olivary bodies and penetrate the median raphe, while others have a serpentine direction toward the pons. The conspicuous fact regarding these fibres is that, whatever be their course, all seem to decussate at the middle line, and this decussation in fact constitutes the median raphe, the significance of which has not been accurately estimated. The ultimate destination of these fibres is still uncertain. M. Luys thinks it possible that, after decussating, they enter one of the deposits of gray matter which are seen close to the raphe, and which are composed of large cells with interlacing processes. Others probably pass to the network of cells of the olivary bodies on the side opposite to that on which they entered the medulla from the cerebellum. In support of these views, he showed sections from a case of congenital atrophy of one lobe of the cerebellum. The inferior cerebellar peduncle on that side was completely atrophied, and so also was the olivary body on the opposite side, which contrasted strikingly with the full development of the olivary body on the same side. This important observation speaks strongly for the view advanced by M. Luys, that there is an intimate connection between the olivary bodies and the cerebellar fibres.—*The Lancet*, July 24th.

Treatment of Respiratory Diseases by Means of a Portable Inhalation Apparatus.—Dr. Hansmann, of Mesan (Tyrol), has devised a little apparatus which he calls an "inhalation respirator" and which he has found very serviceable in the treatment of various affections of the organs of respiration. Its action is said to disinfect, deodorize, and also diminish expectoration. This little contrivance is made of tin, and consists of a mouth-piece and a receptacle for the medicine, the two portions being separated by a sieve. The receptacle also has external perforations, so that the external air may have ready access to it. The medicine is dropped upon cotton, and this is placed in the receptacle, so that with each inspiration the breathed air carries with it the volatile elements of the drug. The whole apparatus is conveniently small and has a pleasing shape, besides being readily adjusted to the mouth. Patients may wear it during their promenades. Among the medicaments which the writer has employed in various affections, such as putrid bronchitis, bronchiectasis, phthisis, may be mentioned rectified tar, the unguentum picis (1:4), carbolic acid solution (five to ten per cent.), and turpentine. The author finally cites typical cases, which exemplify the gratifying results which he has obtained from the persistent use of his little apparatus.—*Berlin. klin. Woch.*, August 23, 1880.

Resorcin and its Antipyretic Action.—In a series of articles (*Allgemeine med. Cent. Zeitung*, July 28t and 31st, and Aug. 4, 1880) Prof. Lichtheim, of Berne, calls attention to this powerful drug, which, althoug discovered several years ago by the chemist Hlasiwet in Vienna, has not hitherto received the attention o the medical world. Dr. Andeer, of Würzburg, quit recently studied the therapeutic value of resorcin and Lichtheim has supplemented this study by series of clinical observations, which certainly meri professional consideration. Resorcin has derived it name from its similarity to orcin (contained in coloring moss termed orseille) and certain resins especially galbanum. The chemical formula o resorcin is said to be C_6H_4 (OH_2) and it belongs t the series of phenols. Its antiseptic properties ar in every way equal, if not superior to those of carboli acid. In febrile conditions its administration pr duces a rapid and considerable lowering of the tem perature, which exceeds that of quinine and sali cylic acid, but this effect is of short duration. dose of two or three grammes produces, after a fe minutes, vertigo, tinnitus aurium, facial congestion, an accelerated respiration, and an increased pulse-rate. In ten or fifteen minutes perspiration begins, and about fifteen minutes later the patient is bathed in sweat. About one hour after its administration the patient's pulse and temperature are normal. This antifebrile action is, however, not invariably so marked, and in this respect resorcin appears to be subject to the same variations that characterize other antipyretics. Besides its very temporary effects (pulse and temperature generally attain their former height some three or four hours after the cessation of the drug), resorcin appears to have certain other drawbacks, which until now have not been remedied. Phenomena of excitation usually precede its febrifuge action, and these may sometimes assume the the shape of active delirium or other cerebral manifestations. Coma was also observed in one case. On the other hand, all these acute symptoms are quite evanescent, and in no case was any deleterious "after-action" noticeable. Lichtheim thinks that if we should succeed in doing away with these unpleasant symptoms, resorcin would soon become as widely known and used as quinine and salicylic acid.

In non-febrile conditions and on healthy subjects the new drug appears to have no action at all. The pulse and temperature show no change, neither were any cerebral phenomena observable, barring perhaps a slight vertigo and moderate tinnitus aurium. Resorcin is easily soluble and readily absorbed, and this appears to account for the rapidity of its action and its powerful effects.

Pneumonia, erysipelas, and typhoid fever are not much influenced in their course by the administration of resorcin, but on intermittent fevers it seems to have a specific antidotal action. As a disinfectant, and for external antiseptic application, resorcin may also be conveniently employed.

The Treatment of Rupture of the Uterus.—In a recent number of the *Zeitschrift für Gynækologie*, Dr. Frommel, of Berlin, reported a case of perforating uterine rupture, which had been successfully treated by establishing abdominal drainage and irrigating the peritoneal cavity with carbolized water. The author now reports two new cases, which, under similar treatment, likewise recovered. The first case was that of a small woman, aged forty, who had given birth to twelve children. Three of them had been delivered by artificial means. During her last confinement the labor-pains suddenly ceased, and a subsequent very painful examination showed that the child had partially escaped from the uterus into the abdominal cavity. With some difficulty a dead fœtus was extracted, and an examination now revealed a transverse rupture of the uterus at its lower segment near the cervical junction. The uterus was almost completely torn off, only anteriorly and to the left a bridge of tissue existed, measuring about five to six centimetres. The peritoneal coat, however, was not ruptured, but had been stripped off by the protruding fœtus. The entire cavity was cleansed by a copious irrigation of a warm aqueous solution of carbolic acid (two per cent.), and a thick drainage-tube was then inserted. Ice was applied over the abdomen. The patient never vomited, her pulse was always good, her temperature never rose above 100.4° F. Only one intra-uterine injection was practised through the drainage-tube, which was removed as soon as the discharge ceased. This occurred on the twenty-sixth day after the accident. Two days later the patient was able to leave her bed, and shortly afterward was discharged in apparently perfect health.

Case II. was that of a woman, thirty years old, who in her youth had suffered from rachitis. She had had three confinements, each with tedious labor. Uterine rupture took place, perhaps in consequence of the administration by a midwife of four ergot powders. Prof. Schröder succeeded in extracting the dead child, which, together with the placenta, was found lodged in the abdominal cavity. The treatment was in all respects similar to that adopted in the first case, with the difference that, in the present instance, carbolized injections were made through the drainage-tube every time the temperature rose above 100.4° F., which occurred on several evenings.

In his remarks on the successful termination of these cases, the author observes that this plan of treatment is much to be preferred to laparotomy. But he admits that it is applicable only to cases in which septic infection has not already taken place, though he adds that laparotomy under such circumstances would also necessitate a bad prognosis.-*Centralblatt für Gynæk.*, August 28, 1880.

The Hypodermic Injection of Alcohol and Similar Substances in Diseases of the Blood-Vessels.—Dr. Schwalbe, of Magdeburg (Virchow's Archiv, vol. lxxvi., p. 511), relates his experience with this method, suggested to him, as early as 1872, by V. Langenbeck's recommendation of the subcutaneous use of ergot dissolved in alcohol and glycerine. Schwalbe found alcohol injections serviceable in varices, varicocele, and hemorrhoids. Hasse also treated successfully several cases of telangiectasis. Schwalbe practised above 3,000 hypodermic injections with a solution of ethyl alcohol, varying in strength from fifteen to eighty per cent. In all these cases suppuration was observed only eight times: twice owing to the use of an unclean canula, twice because a blood-vessel had been pierced, and four times because the injections were made at insufficiently long intervals. Schwalbe's method is as follows: the hypodermic canula is first introduced under the skin, in the direction of the vessel, and at a distance from it of about three centimetres. Then, provided a blood-vessel has not been struck, the syringe is secured to the canula and its contents slowly injected. If the skin show considerable tension he immediately stops the injection, rapidly withdraws the canula, and places a finger upon the puncture. The subsequent pain varies in intensity, and may last two hours. Then the skin usually turns red, and begins to swell, sometimes for a considerable distance beyond the point of injection. After several days, however, all these symptoms disappear, and the operation may then be repeated, the point of injection being moved a little nearer to the vessel. In this way a cure is usually effected after from three to ten injections.—*Schmidt's Jahrbücher*, July 26, 1880.

A New Medical Journal, called the *Rocky Mountain Medical Review*, has recently been started at Colorado Springs, Col. It is a monthly journal and is the organ of the State Medical Society. The editorial announcements state that it will be devoted to encouraging a better knowledge of the state as a sanitarium, and to promoting the general interests of the medical profession there. The first number contains some very well written criticisms, and the general appearance of the journal is highly creditable to its editors.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, November 13, 1880.

THE CLIMATE-CURE OF PHTHISIS.

In a previous issue we made some remarks regarding climate-cure in general, and alluded at the time to the necessity of a closer study of the subject on the part of physicians. The importance of this question of climate-cure can hardly be overrated, and we make no excuse, therefore, for discussing it again in that particular phase which relates to phthisis. We have intimated that physicians were by no means sufficiently well informed, as a rule, upon this subject; and when it comes to exactly fitting the proper climate to each particular form or stage of phthisis, we fear that few, if any, can uniformly succeed.

This last fact, however, is not so much the fault of the physician as the fault of the science. Climate therapeutics has not yet reached even an approach to maturity as a practical science. There are, certainly, some general facts that are quite well established in regard to the proper kinds of climate for the sick, but an examination of the literature of the subject will be apt to leave the reader in a state of much confusion as to where are the ideal climates, and which he should most recommend.

There are five fundamental characters which are especially studied in connection with the therapeutic effects of any climate. These are its relative humidity, its purity, its temperature, equability, and density, the last being a quality that has been more especially investigated of late years. In addition to these there are various minor qualities, such as the prevailing winds, the diathermism, the electrical tension, prevalence of ozone, etc., which have also to be considered. At present, it is probable that cool, dry, and equable climates have received the strongest commendation. Dr. Henry Bennett claims that a climate of this kind is the ideal one for phthisis, and speaks strongly against cold of mountain sanitaria on the one hand, and the warmth and moisture of such places as Madeira and Florida on the other. Mentone and the neighboring places on the Mediterranean furnish, he considers, the conditions in question most perfectly. In this country the coast of southern California has, to some extent, the same desirable characteristics. But authorities are now arising, who, while not denying the value of coolness and equability, claim that a rare atmosphere, provided it is dry, is an element that is of very great importance in the cure of phthisis. The increase in number of mountain sanitaria in Europe, and the growing popularity of Colorado, furnish evidences that physicians are looking with favor upon this peculiarity of climate as a help in pulmonary disease. The fact that phthisis does not occur in localities at an elevation of 5,000 or 6,000 feet or more, is adduced as an *a priori* argument in favor of the special value of a rare atmosphere. Some statistics have been compiled to support this view, and ingenious physiological theories advanced to satisfy the craving for scientific explanations. Now, while it cannot be denied that the climate of elevated regions often does a great deal of good to phthisical patients, its real value is far from being perfectly determined, and we are by no means sure that it has not been exaggerated. It is true that phthisis does not exist at high altitudes, but neither does it exist at certain low altitudes, such as that of the islands to the north of Scotland, and in other places along the north coast of Europe. And yet these localities would probably be the last to be recommended as sanitaria for the phthisical. Furthermore, although high altitudes may have a monthly or yearly equability of temperature, yet the rarity of the air makes it impossible that there should not be sharp diurnal rises and falls, corresponding with the rise and setting or even clouding of the sun. The theories to explain the special physiological effects of a rarefied atmosphere, contain, doubtless, some elements of truth, but they are incomplete and conflicting. We may instance the theory of Jourdanet, who believes that the inhabitants of high altitudes have a deficient supply of oxygen and an excess of carbonic acid in the system, a condition which secures to them immunity from phthisis. Dr. Wm. Marcet has recently tried to prove that at high altitudes oxygen penetrates the pulmonary tissue more rapidly and easily. In this way he would explain his observations to the effect that as a person ascends to a higher level, the amount of oxygen inspired decreases, while the amount of carbonic acid expired increases. A prevalent belief is that a rare atmosphere acts upon the pulmonary surface like a cupping-glass. In this way it hurries on the blood, and relieves stasis and threatened inflammation. We can only conclude from all this that there is as yet neither sufficient physiological knowledge or statistical evidence to settle definitely the true value of high altitudes.

We would not be understood, however, as inclined to underrate the efficacy of these regions. The atmosphere always presents the essential elements of purity and dryness. It is also either cool or cold, and has a certain kind of equability. There is, just now, hardly any more popular health-resort than Colorado. And this state furnishes a much better kind of high altitude than can be found in Europe, since at the same level the temperature is milder and vegetation flourishes.

But while climates, such as Mentone and Colorado represent, are claiming so much superiority, it should not be forgotten that there are other regions which have very strong advocates and which undoubtedly are in many cases preferable. The cold, dry balsamic, and tolerably equable climate of the Adirondacks in winter has a well-attested value in the treatment of phthisis. The low temperature and dryness of Minnesota, the pine districts of Georgia, and the warm and equable climate of Florida, have given these places a deserved reputation as sanitaria. Despite the statements that warmth and moisture are bad for phthisis, there is no question whatever as to the efficacy at times of sea-voyages, or of a winter in Florida or Madeira.

With all these facts before us, it is easy to see how difficult it may often be to form a good judgment regarding the best place to which a phthisical patient should go. There is but one common element underlying the whole of climate therapeutics, and that is the change of air. In each individual case there are, of course, certain facts which make the determination of a suitable climate easier. These are well enough known, and we need not dwell upon them. But we would insist that, with the present increasing tendency to treat phthisis by climate-cures, the physician should be aware of the responsibility he is under in deciding where the patient shall be sent. There is undoubtedly a best place for each case of phthisis; and there is not any ideal spot as yet known which meets all conditions and is suitable for all phases of the disease. The problem is to fit the proper climate to each patient. And that this may be done intelligently and successfully, further study of climate therapeutics is needed. We can only say now that probably dryness, purity, coolness, and equability meet the most indications, but that atmospheric rarity, coldness, warmth, ozone, electricity, balsamic odors, and various local conditions or personal idiosyncrasies, must often be given a high prominence in the selection of the best climate for a particular case of phthisis.

THE RATIONALE OF NERVOUS SLEEP.

SEVENTEEN years ago, in 1843, Mr. James Braid, M.R.C.S., of Manchester, England, wrote a book entitled "Neurypnology; or, the Rationale of Nervous Sleep." A few years later the same author published a work on trance, and in 1852 a second work on hypnotism.

Mr. Braid wrote these books at a time when the excitement over mesmerism was at its height. Harriet Martineau had become a convert, and, though unable to believe in a God, was profoundly convinced that some people could see through a board, and that her abdominal tumor had been dissolved by magnetic fluids. Mesmerism had fastened itself upon medicine. There were mesmeric infirmaries, mesmeric hospitals, and a vast crowd of medico-magnetic healers. Even educated physicians of high standing endorsed it and used it in their hospital wards.

In Mr. Braid's first book, while some of the phenomena were accepted as facts, the theory of a magnetic fluid, or of any occult influence, or *deus ex machina*, was denied; and the work was an effort to show what phenomena were genuine, and how these might be explained by natural laws. But Mr. Braid was too skeptical for the mesmerists and too liberal for the conservative members of the medical profession. The consequence was that his work was ignored by subsequent physiologists, and it dropped into oblivion, along with the delusions which it exposed. Mr. Braid's memory is handed down to posterity by Mr. Allibone, with the single comment, quoted from Dugald Stewart, "Too great skepticism is equally the child of imbecility with credulity."

The author of Neurypnology was thus forgotten, but his memory has been recently and unintentionally revived. A short time ago, Professor Rudolf Heidenhain published, at Leipsic, a treatise on hypnotism. The facts and conclusions given in this treatise were very similar to those of Braid, though Heidenhain appears to have been entirely ignorant of that author. This recent work on hypnotism, however, was at once noticed by physiologists, and the subject received prominent attention at the last meeting of the British Medical Association.

Professor Heidenhain made most of his experiments upon medical men and students. He found that, out of ten persons, three or four were susceptible of the hypnotic influence, these being generally of a nervous temperament, though not abnormally so. He distinguished, as did Braid, three stages of the condition, which differ chiefly in intensity. The patient, being subjected to gentle and continuous sensory stimuli, and his attention being fixed, falls into a hypnotic state. If this is slight in degree, he remembers what has passed when he returns to his normal condition. If the sleep is deeper, his remembrances are partial. If he reaches the third stage, all memory of what occurs in it is lost.

A patient in the third stage of hypnotic sleep presents many curious phenomena. His consciousness and volition are in abeyance. These faculties seem to be inhibited, leaving the subject mostly under the control of the basal ganglia. His sensory perceptions remain, but are much changed. He is very sensitive to some kinds of stimuli, such as cold and heat, a breath of air, gentle strokes, the sounds of the voice. On the other hand, he may be cut, pinched, burned, or a pistol may be fired off close to his ear, and there is no response.

There is a strong tendency to imitation. He repeats sentences that are uttered, follows a person about the room, imitates muscular movements. There is a tendency to perform such actions as the habits of the individual have accustomed him to; the proper initiatory stimulus being given, the patient becomes an automaton. Reflex sensibility is greatly heightened, as might be expected, from the lessened authority of consciousness. There is a tendency to tonic spasms; and, what is curious, such spasms may last for days after the patient has come out from the hypnotic condition. Stimulation of different parts of the skin brings out different reflex effects.

Braid tried to deduce from this a certain law which he called that of the "anatomy of expression." His theory was, that if the muscles oftenest used in connection with the expression of a certain emotion were stimulated, such emotion, by association, would be called out. In other words, he believed that in the hypnotic state the higher faculties were set at work by stimulating some of the lower organs. He asserted that facts proved his theory. Heidenhain found that when he stroked the back of the neck, between the fourth and seventh cervical vertebræ, the patient emitted a gentle sighing sound. By stroking the left side of the head, he produced aphasia; by stroking both sides, the patient became cataleptic. There were many other interesting reflex phenomena. Thus, the hypnotized eye is color-blind and its accommodation paralyzed. By pressure on, or by speaking against the seventh cervical vertebra, or the epigastrium, imitative sounds were produced. So, a tuning-fork, placed on the same regions, produced a like effect. By this latter instrument the sensitive regions could be mapped out.

It is stated by Heidenhain that the respirations of the hypnotized persons are increased fourfold, and the pulse is also more rapid than usual. Braid, on the other hand, asserted that the respirations were lowered, and he believed that the carbonization of the blood thus resulting was one of the factors in producing the hypnotic condition. The other factors were absorbed attention and gentle sensory stimuli. Among other phenomena which this latter author pointed out as belonging to hypnotism, were an exaltation of the imagination, the excitation of memory by sensory stimuli, an extraordinary sensitiveness to heat and cold, and the existence of "double consciousness." By this latter was meant that a person, when hypnotized, might do things which he had no remembrance of when he returned to his normal condition. When hypnotized again, however, he recalled, with perfect readiness the acts done in his first hypnotic state. This phenomenon, which is well enough known now, Braid claims to have first discovered.

We have no intention of giving any complete account of the phenomena of hypnotism. There is much yet to be learned in regard to it, and much to be inferred from it. As it appears now, the condition at the base of it all is one in which there is an inhibition of consciousness and volitional control, with extraordinary exaltations, depressions and perversions of the sensory apparatus, both special and general. Even apart from Braid, hypnotism is not a new thing, and, although since his time no one has studied it so thoroughly as Heidenhain, there have been contributions by Carpenter, Huxley, Beard, and others, which should not be forgotten. But no one has ever spent so much time and labor, or had so wide an experience with hypnotic persons, as Braid; he was the first and largest contributor to its literature, and it is but justice that his name be not forgotten.

Reviews and Notices of Books.

Diseases of the Pharynx, Larynx, and Trachea. By Morell Mackenzie, M.D., London. Pp. 440. New York: William Wood & Co. 1880.

Diseases of the Throat and Nose, including the Pharynx, Larynx, Trachea, Œsophagus, Nasal Cavities, and Neck. By Morell Mackenzie, M.D., London. Vol I., pp. 570. Diseases of the Pharynx, Larynx, and Trachea. Philadelphia: Presley Blakiston. 1880.

Hygienic and Sanative Measures for Chronic Catarrhal Inflammation of the Nose, Throat, and Ears. Part I., pp. 166. By Thomas F. Rumbold, M.D. St. Louis: Geo. O. Rumbold & Co. 1880.

A Practical Treatise on Nasal Catarrh. By Beverly Robinson, A.M., M.D. (Paris) pp. 182. New York: William Wood & Co. 1880.

The two books first named are the same, but the titles differ slightly. The work of Dr. Mackenzie has been wisely chosen as one of *Wood's Library of Standard Medical Authors* in the series for 1880, for there is a demand for a treatise on this subject which shall bring the latest literature before the profession. The volume before us is to be shortly followed by a second and concluding one on the Œsophagus, Nasal Cavities, and Neck. The author of this work has had a large experience in both private and hospital practice extending over the past twenty years, a period of time that has witnessed the development of a special practice in laryngology. His methods for recording the details of history and treatment are known to have been accurate, and when the large number of cases thus observed is taken into account, we have a right to expect that the author's book will be one of the best of its kind that has yet been produced. An exhaustive review of such a book, however desirable, must give way to some practial views concerning its salient points, and it may, therefore, be stated in general that its plan of construction is a good one. At the beginning there is a condensed but sufficiently complete scheme of the special anatomy most needed in connection with the text, followed by brief but clear directions for the examination of the pharynx, the subject first treated of in the book. Illustrative woodcuts are introduced where it seems desirable to make the description of the instruments recommended for use more easily understood; and it may here be stated respecting the illustrations throughout the book, that they appear to have been well selected, without the unnecessary profusion that characterizes some literary efforts.

The arrangement of the diseases treated of appears to be very satisfactory, the nomenclature adopted being calculated to make the subject clear to the reader; but all doubts respecting this point vanish under the author's *definition of subjects*, which comes next in order, and is remarkably clear and succinct. The systematic treatment of each subject is strictly adhered to throughout, and the entire text is well written—it is, in fact, a marvel of good English, the clear and precise style rendering the book's perusal easy and pleasant, although the matter is by no means unscientific.

The author exhibits a discriminating judgment in availing himself of the literature at his command, bringing most effectively into the text the thoughts of others, yielding full credit either in the text or in the foot-note references, the latter being numerous and conveniently arranged.

Many of the chapters in Dr. Mackenzie's work are monographic in merit, and in themselves would command attention. The chapter on diphtheria may be cited as an example of this kind, its history being given from Hippocrates to the present time. Of the etiology, symptoms, pathology, and prognosis under which, respectively, each subject is treated, we can in general only speak in praise, but as regards treatment, Dr. Mackenzie's methods will not, we feel sure, command the same endorsement here that will be most heartily awarded to most of his writings. There is here a growing dislike for ready-made preparations such as Dr. Mackenzie recommends in his book for almost every symptom. These may serve for the hasty, not to say superficial, treatment of hospital patients, but it is safe to predict that they will not be generally accepted by physicians for use in private practice; and, indeed, it may well be considered a reflection upon one's intelligence to have thrust into prominent notice, on almost every page of the book, the preparations of the "Throat Hospital Pharmacopœia." That the author should become, from strong contemporaneous influences, partial to local treatment is not strange, especially when we consider how strong the tendency to such methods has been. That this is notably a weakness in specialism generally goes without saying, and we allude to the matter here but briefly, feeling that, whatever the practices abroad may be, upon the whole the abuses of local treatment among physicians here is daily becoming less popular. We shall have to be content with citing a few examples only of the author's treatment: in tonsillitis, for example, the tincture of aconite, in doses of two to five minims every three hours, is recommended as sometimes efficacious. For this remedy, he informs us, we are in great measure indebted to homœopathy. The homœopathicity of this drug is claimed by homœopathic writers to lie in its power of setting up the essential phenomena of fever, and of its action upon the same parts and in a similar manner, that it controls this condition when already present (Hughes). With this therapeutical idea for a guide, infinitesimal doses are administered by the exclusive system of practice, and we are unable, therefore, to understand why Dr. Mackenzie uses such large doses—one might hesitate long before thus administering the drug "in doses of two to five minims every three hours," especially as the British pharmacopœia directs that the tincture shall be prepared from the root.

The author speaks of controlling, in all cases, the hemorrhage following excision of the tonsils by the use of a tanno-gallic acid gargle, which is composed of the following ingredients: ℞. Acid. tan., gr. ccclx.; acid gallic, gr. cxx.; aqua, ℥ j. M. Half a teaspoonful of this mixture is to be sipped at short intervals in order that during the act of deglutition the styptic fluid may be worked into the cut surface of the tonsil, "and," he then says, "the hemorrhage is effectually restrained in all cases." We should hesitate to allow a child to swallow many sips of this mixture, and, indeed, we are inclined to doubt its infallibility "in all cases." In taking leave of Dr. Mackenzie's book, we can but say that it will justly take its place among the standard medical publications of the day, and whatever we may think of its therapeutics, it is, to say the least, a faithful record of the least objectionable features of a period in special practice when the local treatment of some affections has been greatly overdone.

We speak thus regarding this matter from a strong conviction that other specialties must eventually undergo the same reformatory elimination as to treatment that the past twenty years has witnessed in gynecology, where the shameful practice once existed of applying cauterizing agents to the os uteri of every confiding woman who submitted herself for treatment. The book under review is well made in both editions; the first-named is uniform with the other works in Wood's library, and the last-named is well printed in plain type.

The two little books of Drs. Rumbold and Robinson, although touching on the same topic so extensively treated of by the Englishman just noticed, are, perhaps, better suited for popular reading than the use of the physician, for they both show considerable thought in the hygienic aspect of the subject. Dr. Rumbold's book is to be followed by Part II., which will be devoted to "therapeutic and operative measures." As far as chronic inflammations of the throat and nose are concerned, this author's methods (hygienic?) do not greatly vary from those recommended by others, but he has, as a laryngo-aurist, carried into the field of aural surgery some views that are quite novel in their character. As such literature in this country has not hitherto had an existence, we may be pardoned for drawing upon Dr. Rumbold's book for some examples of its earliest efforts. The author dives into the subject rather abruptly, for he begins with a chapter on cleansing the ears. He says: "Whenever the secretion of an inflamed middle ear is so excessive that the mucous membrane cannot absorb it, then it must be removed by mechanical means. The means taken to accomplish this should not cause the least irritation, and it should apply the irrigating fluid to every portion of the tympanic cavity." The author's means for the accomplishment of this irrigation consists in forcing warm salt water into the middle ear through a tight-fitting appliance introduced into the meatus externus, that permits the water to rather slowly escape again from the ear through a small opening; this irrigation is to be continued while the patient performs a complete circle with his head from five to ten times, the number of revolutions depending on the size of the opening in the drum (drum-head?). The object in performing these circular movements is to allow every portion of the tympanic cavity to be, at some stage in the procedure, in a position to favor the escape of the retained air that otherwise would prevent the water from coming in contact with all portions of the cavity. The author's allusion to the absorption of the secretions of an inflamed middle ear by the mucous membrane implies a greater confidence in the curative powers of nature than most physicians possess; and his method for removing the unabsorbed secretions is certainly a very wide departure from that confided to nature in the first instance. It is not likely that this teaching will become popular either in domestic or other practice. In the next chapter the author introduces the subject of the teeth. He says: "I have observed for many years that diseased teeth and gums tend to maintain the catarrhal inflammation of the mucous membrane of the nasal and pharyngo-nasal cavities, the throat and ears." In what manner diseased teeth produce these effects the author does not make clear, nor does he state why he has kept this important knowledge from the profession for so many years. The book is printed on good paper, but is full of typographical errors, etc., showing an undue haste in preparation and publication.

Dr. Robinson, at the outset, enters into a consideration of the prophylaxis of the subject, which, however, seems intended to cover the same ground occupied by Dr. Rumbold under the head of Hygiene and Sanative Measures. If the author intended this portion of the book for the instruction of physicians it could well have been abbreviated, or even omitted altogether; if for the nursery, it would bear simplification. Space will not permit a lengthy examination of the merits of this work, but before quitting the subject we would again draw the reader's attention to some points that will further illustrate the influence some of the tendencies of special practice have in the direction of bringing our therapeutics into further disrepute: we hope that pointing out the defects in the book before us may have some influence upon those who are interested in these matters and thus hasten a much-needed reform in this direction. We shall, therefore, begin by an examination of Dr. Robinson's treatment of the acute coryza of infants. It will not be necessary to bring in here all that is said concerning the management of these cases; we will only allude to a local method described on page 68. This treatment consists in blowing into the anterior nasal passages of the infant, by means of a powder-blower, the following mixture: ℞. Camph. pv., sacch. alb., āā ʒ ss., acid. tannic., grs. xl.—lx. After one or two applications of this powder the infant, it is asserted, is enabled to sleep, and the mucus is prevented falling back into the throat. The author says: "Another great advantage to be gained by a thorough application of this powder is the power which it gives to the infant by opening its nasal passages to suck its mother's breast, or take the feeding-bottle without being obliged to let go its hold with a distressing cry every few minutes." This will, perhaps, be considered a doubtful procedure by physicians, although the author gives some encouragement to the timid who may feel disposed to try the treatment on his recommendation; on page 153 he says: "In my opinion local treatment (no matter what may be its conditions) is *never* so efficacious as it is frequently believed to be." And on page 154 the author states that it is *physically impossible* for powders to reach the numerous folds and infractuosities of the mucous membrane lining the nasal fossa. Thus, in speaking of parts long affected by chronic processes, but respecting the acute coryza of infancy, the author says: "So soon as these passages (the nasal) are at all inflamed, they become rapidly almost impervious to air" (page 57). Further on, in the treatment of acute coryza in general, the author says (page 61): "In my own experience, however, I have found it preferable in these instances to give the first night a full dose of some simple diuretic and diaphoretic medicine which acts upon the skin and kidneys, but is not followed by almost absolute loss of appetite and great dulness of intellect the next morning." We shall not pause here to quote the formula that possesses the power to act as a diuretic and diaphoretic at the same time, believing, as we do, that the skin and kidneys cannot be thus influenced by treatment.

In speaking further of acute coryza the author gives the following advice: "If one is compelled to go out into the open air when it is cold, during an attack of coryza, it is wise to protect the ears by some outer covering, as it prevents, in a certain degree, the coryza from extending itself into the pharynx, and still further along the respiratory *tract*." This statement will be quite new to many, but further confirmation will be required before it is generally accepted.

We rise from a somewhat careful perusal of these works impressed with the belief that the sooner a line is drawn between medical works intended for the instruction of the profession and those apparently written for their use, but really intended for the laity, the better it will be for the interests of scientific medicine.

Diploma-Mills in San Francisco and Boston.—The *Pacific Medical and Surgical Journal* gives an exposé of a certain "eclectic" medical school in Oakland, California. From its account this school does not appear to furnish very much more education than did Dr. Buchanan's colleges. Eleven persons were graduated, it is said, in 1879, and only one of these had had more than a year's training. Furthermore, three of these medical yearlings have been appointed to professorships in the college. There are still worse facts regarding this institution which the editor of the *Journal* holds in reserve. As the existence of a bogus college must entirely neutralize the effects of the medical law in California, the profession of that state ought to do everything possible to put a stop to its work.

The Boston *Herald* has recently exposed a bogus institution known as "The New England University of Arts and Sciences," which has flourished in the modern Athens for several years. The "dean" in this case was a "Dr." Henry C. Stickney. The University was incorporated by the New Hampshire Legislature in 1875, but the charter was repealed the next year. The diplomas were chiefly medical, and cost from $100 to $145. Some of them had been presented to the Board of Health of Illinois. Stickney acknowledges most of the charges made against him, and his business will doubtless be permanently closed.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, October 13, 1880.

Dr. Satterthwaite, President, in the Chair.

CASE OF DOUBLE INTUSSUSCEPTION—POLYPOID GROWTH OF INTESTINE.

Dr. E. C. Wendt presented a specimen of the above, for which he was indebted to Dr. Haupt, House Physician to the St. Francis Hospital, who was one of the attending physicians during the patient's last illness.

A tinroofer, æt. 24, who had previously enjoyed perfect health, was suddenly seized with severe abdominal pains. This occurred on Thursday, the 30th of September last, while the patient was walking the streets in search of employment. Although, as he stated, the pain continually increased, he was nevertheless able to return to his home, and subsequently to consult a physician. The pain meanwhile had grown so intense that he lost all mental control, and even attempted suicide by jumping into the East River. Dr. Haupt saw him for the first time on the evening of the following day, *i.e.*, October 1st. The following observations were recorded by him: Patient found in dorsal decubitus, with knees drawn up, complaining of nausea and pain over the entire abdomen. This was most severe in ileo-cæcal region. It was further learned that since Wednesday no movement of the bowels had taken place, nor had the escape of flatus been noticed. The urine had been scanty, and there was pain on micturition. Pulse was 118, but a febrile movement was not noticed. He complained very bitterly of a distressing thirst; but, though he drank repeatedly, the swallowed fluid was almost immediately returned. Acute intestinal obstruction was diagnosed, and opium and quinine ordered. On the following morning the patient was again seen, and though he complained less of pain, the symptoms of obstruction were now more marked. Spontaneous vomiting of fluid matter, having an unpleasant intestinal, though not decidedly fecal odor, now occurred. The oppressive thirst continued. There had been no rectal evacuation, no escape of flatus; the urine was almost suppressed. Pulse feeble, 152; temperature still normal. Dr. Haupt then advised him to enter a hospital in order to have laparotomy performed, as this was his only chance of getting well. Another physician having been summoned, who gave his opinion that the patient would get well shortly, Dr. Haupt saw no more of the case until Sunday morning, when curiosity prompted him to make another visit. The vomiting was now almost incessant, the fecal odor of the vomited matter was more pronounced, and the patient was evidently much worse. The case was thought to be one of intussusception at this time. On Monday the patient was brought to the St. Francis Hospital, a distance of about ten blocks, but he died very shortly after his admission.

At the autopsy, performed shortly after death, the following appearances were noted: The body was somewhat emaciated, the face looked pinched, the abdomen was but slightly distended, rigor mortis incompletely developed. Palpation of the supple belly revealed nothing in the nature of a tumor, not even a conspicuous hardness was anywhere discernible. On opening the abdomen all the viscera appeared to be normally situated. A coil of small intestine in the hypogastric and left inguinal regions was at once remarked from its conspicuous reddish brown discoloration. In this neighborhood slight adhesions of recent origin existed, so that the loops of intestine were here loosely matted together. Elsewhere the signs of peritonitis were less marked. There was slight general congestion, with occasional areas covered by delicate pseudo-membranes, and the peritoneal cavity contained about three ounces of a turbid, sanguinolent fluid. Upon closer examination it was ascertained that the small intestine was invaginated at a point about midway in distance between the duodenum and ileo-cæcal valve. A constriction was found in the gut at a point corresponding to the site of most intense congestion and discoloration. Above this spot the intestines were distended with gas and fluid. A soft, sausage-like tumor was felt below the constricted portion, extending downward somewhat over eight inches. Beyond this point the intestine was still of a purplish hue, and appeared to be distended by thick contents for the distance of several feet, where the distention stopped rather suddenly Below this place the intestine was completely empty, constricted, and shrivelled up into thin, cord-like masses. The invaginated portion was then removed, together with a piece of intestine on either end of it. On opening the gut above the constricted portion, ordinary intestinal contents of a somewhat fecal odor escaped. The other end of the gut, however, contained only a grumous bloody mass without any marked odor, and some fluid blood.

The intestine covering the invaginated portion was then opened, disclosing the latter, which appeared to be bathed in the bloody grumous matter above mentioned. After washing the mucous coat of the inclosed part it was seen to be somewhat roughened, and the entire piece of intestine was deeply congested, greatly swollen, and somewhat macerated. A further examination showed that the entire eight inches of invaginated gut contained a second intussuscepted piece of gut having about the same length. The constricted portion was found to correspond to what appeared to be a superficially ulcerated mucous polypus about the size of a hickory-nut. The intestinal walls opposite this polypus were extremely attenuated, and in fact, while the specimen was being removed, they ruptured, allowing a very small quantity of pus to escape. The most internal of the invaginations, judging from the absence of extensive pathological changes, was apparently the more recently formed of the two.

This case appeared to have a two-fold interest: first, as regards its etiology, and second, as regards its surgical aspects. Laparotomy was evidently indicated from the first, and its performance would probably have saved the patient's life.

Dr. Briddon remarked that there were several cases of intussusception on record which were associated with polypoid intestinal growths as a cause. Such an one formed the text of an exhaustive monograph by Dr. Samuel Whitall, of this city. In regard to the indication for laparotomy, he did not think that there was any question.

Dr. Howe concurred in the latter opinion, and expressed the belief that many patients were allowed to die whose lives could have been saved by the operation.

Dr. Satterthwaite asked if the injection of air and of water were not sometimes successful. He had read of such cases.

Dr. Briddon believed that such measures should be resorted to before performing laparotomy.

Dr. Ripley remarked that a large number of cases were relieved by injection. He had recently seen a case in point. The patient was a child six months old, who had suffered from symptoms of invagination for twenty-four hours. The injection of warm water was made by means of a No. 13 catheter, attached to the india-rubber tubing of a bulb-syringe. The symptoms subsided immediately thereafter, and the child made a good recovery.

In regard to a question as to whether an injection could pass the ileo-cæcal valve, he stated that such a possibility had been proven on the living subject. He had frequently verified it upon the cadaver. He considered that water was better than air, as the latter tended to keep up an uncomfortable tympanites afterward.

Dr. Briddon remarked that it was generally easy to discover a tumor before tympanites set in.

Dr. Ripley remarked that in his opinion the presence of a tumor could not always be made out. A case of invagination had occurred a few weeks before the meeting, in which the whole question of diagnosis turned upon the existence of a tumor. An accomplished surgeon was called in, but because no tumor could be discovered he declined to operate. An autopsy of the child a few days afterward showed well marked intussusception.

Dr. Howe suggested the advisability of puncturing the intestine in doubtful cases where tympanites existed, with a view to removing the gas.

Dr. Briddon presented, on behalf of Prof. Detmold, a specimen of ungual exostosis of the distal phalanx, which that gentleman had removed by amputation through the proximal joint. Dr. Briddon also exhibited, on behalf of Dr. Hardrich, of Brooklyn, a specimen of

CALCIFIED DEGENERATION OF THE MUSCULAR WALLS OF THE HEART.

I. S——, aged twenty-six years, married, brewer by occupation, German; entered St. Catherine's Hospital, September 11, 1879.

History.—Parents died when he was young, he had two attacks of acute rheumatism before marriage, which occurred two years ago. Has been sick since last April with his present illness, having had but slight temporary amendments at short intervals; this last attack began with vomiting, dyspnœa, præcordial and lumbar pain, and palpitation, rigors and fever, scantiness of renal secretion, œdema of the feet, restlessness, and marked irritability.

Present condition.—Is anasarcous, has orthopnœa, irregular action of the heart, and says he has not voided urine for forty-eight hours.

Physical signs.—Eyes protruding, face cyanotic and tumid.

Chest-expansion deficient on both sides; præcordial region retracted in inspiration; percussion reveals diminished resonance over entire surface; area of cardiac dulness increased, but it was not possible to map it out with accuracy on account of the infiltration of the parietes. Auscultation revealed small crackling râles over entire chest; the heart-sounds were obscure, neither first nor second could be distinguished, being masked by a peculiar swashing sound such as might be produced by walking in shoes filled with water. Abdomen-walls œdematous, fluctuation obscure; legs were swollen, but the scrotum was free from infiltration.

Pulse intermits every tenth beat, irregular in force and volume.

His condition gradually became worse, without marked change in any of the physical signs, and he died September 19th, eight days after admission to hospital.

Autopsy twenty-four hours after death.—Rigor mortis incomplete.

Chest.—About a pint of clear serum in each pleural sac; lungs collapsed and in condition of marked hypostatic congestion.

Heart.—Pericardium firmly adherent to chest-wall and its enclosed viscus; all attempts at separation were of no avail. There were a number of hard nodules in the structure of the heart itself, varying in size from a pea to a hickory-nut. A section of the largest of these presented a cavity filled with disintegrated pus. The walls of the cavity were brittle and in a condition of calcific change; the smaller ones were of the consistency of cartilage, the larger projected into the left ventricle.

Abdomen partly filled with serum; liver enlarged, friable; capsule non-adherent, color dark blue.

Kidneys five inches in perpendicular, three in horizontal, diameter; capsule non-adherent; cortical substance increased and distinctly separated from pyramidal portion by a line of a deeper hue than that adjoining, but the entire organs were deeply congested.

Dr. Briddon also exhibited a malignant tumor of the left breast that he had removed from a married colored woman, aged thirty-five years, a patient at the Colored Home. It presented the usual appearances of carcinoma, but in the centre of the diseased mass was a quantity of effused blood. The specimen was accompanied by a detailed history furnished by Dr. Burke, resident surgeon.

Dr. Ridlon presented an encysted thread which had encircled the penis of a boy, aged seven years, since last Christmas. It was not tight enough to produce any degree of strangulation, was discovered by accident, and was removed without difficulty.

INTERMITTENT HEPATIC COLIC FROM GALL-STONES.

Dr. Satterthwaite presented, on behalf of Dr. Castle, a specimen of multiple abscess of the liver, the result of intermittent obstruction of the common duct by gall-stones. The patient was a widow, aged forty-five, a native of New York. She enjoyed good health until four years ago, when, after an attack of intermittent fever, she began to suffer from attacks of nausea, constipation, and vomiting. Eighteen months ago, during one of these attacks, she became jaundiced, and so remained. At the time of her admission to the Presbyterian Hospital her skin was of a greenish hue, and emaciation was marked. Her stools, for the most part, were clay-colored, but occasionally they would contain bile, especially after an attack of hepatic colic, from which she would suffer at stated intervals. She finally died from exhaustion, September 30th.

At the autopsy the liver was found to be studded with small abscesses and deeply bronzed. At the first division of the hepatic duct were two biliary calculi the size of marbles, lying in each duct. It was supposed that these stones caused an obstruction to the flow of bile by closing the ducts, and when the gall-bladder was sufficiently distended, that the bile overflowed alongside of these calculi.

The Society then went into executive session.

NEW YORK SURGICAL SOCIETY.

Stated Meeting, October 12, 1880.

DR. H. B. SANDS, PRESIDENT, IN THE CHAIR.

NOTES OF CASES OF DISEASE OF THE UPPER CERVICAL VERTEBRÆ.

DR. LEROY M. YALE read the notes made in three cases of disease of the upper cervical vertebræ, and presented one of the patients for further examination and opinion.

CASE I.—J. C——, aged forty-two years, admitted August 12, 1880, to Ward 9, Bellevue Hospital.

Family history unimportant. Father died of heart disease at the age of sixty-six. Patient does not give a history of syphilis. He has had several attacks of inflammatory rheumatism, the first one twenty years since.

Four and a half years ago (March, 1876) patient fell from a trapeze, and was rendered unconscious for a time. He also sustained from the fall a cut of the forehead and lip, a fracture of the nasal bone, and a fracture of the left clavicle. There was pain and loss of power in the left arm for some time. The patient is not aware of any injury to the neck, and after the recovery from the injury to the shoulder was well until August, 1879, when he began to suffer from shooting pains in the back, neck, and forehead. A week later (about August 10th) his neck became stiff, like an ordinary "stiff-neck," as far as he can remember. He was then admitted to Ward 19 in Bellevue Hospital—a medical ward—and treated for "muscular rheumatism." He remained in the hospital three weeks, but without benefit. After leaving the hospital his pains became more severe, especially in the back of the neck. At this time muscular spasms first occurred. They have troubled him ever since, and are excited by a sudden touch, a false step, and the like. On account of these spasms he again entered Bellevue Hospital in December, 1879, and was again sent to a medical ward (No. 26), where he remained until March of the present year. During this stay in the hospital the symptoms were very marked, and during February the rigidity of the neck became greater, and he noticed a lump in the back of the neck in the mesian line. Shortly after this his jaws became stiff, and the lower one protruded. When he left the hospital in March, his head was drawn backward, as at present. He thinks the lump was a large one; that he had greater difficulty in swallowing, and that he could separate his jaws less widely than now. Certain movements of the jaws, as in rolling over a morsel, excite a shooting pain, which seems to start from the temporo-maxillary articulation and to shoot through the shoulder and down the inner side of the left arm.

Appetite good; eats very little solid food, owing to the difficulty of chewing it.

Examination.—Head inclined to left; chin depressed. The latter can be flexed against the sternum, and can be raised till the head is erect, but no farther. Rotation of head not over two inches. Movement from side to side about half normal. Jaws cannot be separated above half an inch. Slight lateral motion of jaws. Has no facial anæsthesia or hyperæsthesia. No marked atrophy of spinal muscles.

In the median line of the neck is a prominence larger than a horse-chestnut, the most prominent part of which apparently contains the spinous process of the axis. No tenderness on pressure. Concussion gives very slight pain. Some slight grating on moving the head.

The finger introduced into the pharynx detects a depression opposite the prominence in the neck, and a relative prominence immediately below it.

There is slight lateral curvature.

On the left side there is some loss of power, more of extensors than of flexors.

No hypertrophy of heart or murmurs.

Dr. Yale remarked that he subsequently learned that two members of the society, whose opinions he valued, had made diagnoses so diverse from his own, that he thought it better to present the patient for examination before stating his own diagnosis.

[The patient was then presented for examination.]

DR. L. A. STIMSON stated that when he saw the patient first, there was some difficulty in opening his mouth, perhaps more marked than at present; that there was great difficulty in swallowing, and that the position of his head was not materially different from what existed when he was presented to the society. He made an examination first with the finger, which encountered, behind the base of the tongue, a hard, prominent swelling that reached forward as far as the base of the tongue. The finger caused a great deal of gagging, and he was unable to carry it down over the base of the tongue. He then introduced a needle to the depth of half an inch into the projecting mass, but no cavity was encountered. The patient was then anæsthetized, and, with the finger, Dr. Stimson was able to feel distinctly a large, smooth, hard mass occupying, apparently, the entire pharynx. He then reintroduced the needle a little more directly than at first, and it struck bone almost at once. He thought it probable that, when the needle was introduced the first time, it passed by the side of the mass. The mucous membrane of the pharynx had a deep, red color, almost livid, and, apparently, was roughened and thickened. Posteriorly, there was a prominent spinous process, just below the occipital bone, which he regarded as the spinous process of the *second* vertebra. There was considerable thickening of the tissues on both sides of the neck, which was not painful, neither did pressure downward produce pain. The motions of the neck were quite free, both rotation and flexion, and were painless. His diagnosis at that time was tumor of the pharynx. None of the symptoms, however, had remained which then led to such diagnosis.

DR. T. M. MARKOE thought that the general features of the case were those of caries with displacement.

DR. G. A. PETERS inclined toward the impression expressed by Dr. Markoe.

DR. LANGE suggested the importance of determining, if possible, whether the elevation posteriorly corresponded with the projection anteriorly.

DR. YALE thought that the prominence in the pharynx was a little lower than the prominence upon the back of the neck, and it gave to him an impression as if one vertebra had slipped backward upon another.

DR. STIMSON thought that the prominence in the throat was lower than the one behind.

DR. YALE stated, with reference to diagnosis, that his own impression was that it was a case of disease of the spinal column, and, without too much insisting upon differential diagnosis, he was inclined to think that it was much more akin to spondylitis deformans than to ordinary caries, and that the nervous symptoms were the result of pachymeningitis.

DR. MCBURNEY remarked that the difference between the present and the previous condition of the patient's throat was very marked. At the time he made his first examination the impression made upon his finger was that the posterior wall of the pharynx was evenly and universally thickened. There was neither a special point of prominence nor depression, and no softening, but the entire posterior wall of the pharynx had a bony feel, and projected forward so as to touch the base of the tongue. Now, he could feel distinctly that the upper portion of the pharynx was quite deep, and that from a level with the upper surface of the tongue downward the pharynx was quite prominent, the difference in depth between the upper and lower portions of the pharynx being from one-half to three-fourths of an inch. He thought the present condition pointed very strongly toward caries with displacement.

Dr. Markoe asked whether the prominence in the back of the neck could be referred to the original injury?

Dr. Yale said the patient believed there was no connection whatever between the two, because, for three years after the receipt of the fall he was as well as ever, and he felt sure that the tumor did not appear until last February.

Dr. C. T. Poore referred to a *post-mortem* case in which he saw a swelling as low as the second dorsal vertebra, covered with very thick, hard integument, and the tumor came forward quite prominently. It was a case of caries, but there was no evidence of fluctuation at *post-mortem*, and there was scarcely any pus. In that case the patient suffered from spasm.

Dr. Markoe believed that Dr. Yale's case could be placed in the category in which there was caries with displacement without any appreciable quantity of pus, but with great thickening of the tissues about the seat of the disease.

Dr. Yale next presented the history of a case which he saw but a few times, but in which he was exceedingly interested. He was enabled to give the termination of the case and to show the specimen obtained at the autopsy, through the great courtesy of Dr. D. M. Stimson. He gave the history as it stands in his case-book, with some additional or explanatory notes (enclosed in brackets) regarding the earlier history of the case copied from the case-book of Dr. Willard Parker.

Case II.—B. D. P——, New Canaan, Ct., aged thirty-three years, occupation carpenter. Seen November 8, 1879. Family history good. Parents both living —one sister living. Patient says that he was always well until three years since, except that, when about eighteen years old, he had a carbuncle upon the back of the neck, scars of which remain. His present trouble dates back three years. About that time he fell from an apple-tree, striking upon the back of his head and shoulders. He was not rendered unconscious nor much hurt. He is not certain whether this fall preceded the pain in the occipital region or not, but is inclined to think that it did.

[Drs. Parker and Stimson subsequently learned that seven years earlier still—*i.e.*, ten years before the time of the taking of this history, the patient had fallen from a building, striking upon the head and shoulders. He speedily recovered from this fall, and continued well until after the second fall.]

This pain [experienced two or three days after the fall]—at first rather a grating sensation on motion—was dull in character. It was, and still is, referred to the neighborhood of the superior curved line of the occipital bone, and rather to its outer part (splenius and sterno-mastoid insertions). It began on the left side, but during the past year the
right side has also been affected in a similar wa
This pain has recently rapidly increased in severit
The patient informs me that he has, during t
course of the disease, been seen by Dr. Willard Pa
ker, whose country-seat is near his home, and th
the doctor considered the case one of deep-seate
cervical inflammation. [From Dr. Parker's notes
learn that he first saw the patient in June, 187
The symptoms then complained of were a stiffnes
pain on jarring the head or on walking, althoug
the man slept and ate well and worked at his trad
"Diagnosis: inflammation of the deep fibrous stru
tures connected with the upper cervical vertebr
Recommended counter-irritation, iodine, and blis
ters. I wished to make a *deep issue*, it was decline
In the summer of 1879 I often saw Mr. Purdy at hi
work; he seemed better; he became worse as col
weather came on."]

Recently he has been troubled with spasms in th
neck, associated with the pain already described.
he is lying in bed he is perfectly easy and slee
well. If he is well placed in a chair, with the hea
supported, he is also comfortable. If, however, h
attempts to move, more especially if to rise, he
seized—this symptom varying in severity—with
jerking of the head backward, a kind of backwar
nodding. He is obliged to steady his head with hi
hand. He has devised for his relief a splint of lig
board to support the head behind and at the side
It rudely resembles the head-piece of an operatin
chair, and is more firmly fixed by tying about it an
the neck an ordinary comforter scarf. Quite recentl
since he has supported his head in this manner, h
has observed a tendency of the head to turn to th
left, and the position is as if the right sterno-cleid
mastoid were the acting muscle.

Patient's general condition is good. Appetite an
sleep good. Muscular system well developed. Ha
worked at his trade until within three weeks. E
amination shows a thickening of the tissues in th
back of the neck, which make a mamma-like eleva
tion at that point. The middle of it is quite prom
nent and suggests a kyphus, but on handling it seem
to be made up of the subcutaneous tissue. Th
muscles of the back are tense, so are the stern
cleido-mastoid and omohyoid.

Concussion on head not painful. Percussion o
spinous processes not painful. Rotation to left no
painful; to the right slighty painful after it has bee
carried a little way. No other motion painful, ex
cept when it is caused by the spasms of the muscle
Has had no pain of any sort except that in the occ
put already described.

No heart-murmur; no history of rheumatism.

On the history and examination I thought I coul
exclude caries of the vertebra for which I was search
ing particularly. As I considered the evident symp
toms to be those of the nervous system rather tha
the osseous, I requested the gentleman who ha
brought the patient to me (Mr., since Dr. W. H
Mahler) to consult Dr. Janeway. The latter referre
the case back to me, calling my attention to th
pharynx, which I had strangely forgotten to examine
There is felt in the pharynx a depression which seem
to correspond to the third cervical vertebral body
This depression Dr. Janeway was inclined to attribut
to a loss of substance from a caseous ostitis. In dis
cussing the case with Dr. Janeway, the possibility o
fracture was suggested, but dismissed as incredib
from the history. Personally I could make no diag
nosis, as I still thought the case unlike any case o
Pott's disease I had seen, and yet was unable to ac

count for the depression. But it was agreed that I should apply a plaster jacket with a head-sling, with the hope that it would steady the head, while the doubt as to the nature of the disease was explained to the patient. I invited Dr. Gibney to examine the case, which he did at my office, but he declined to venture a diagnosis.

The plaster of the first jacket proving to be bad, it was removed and another applied (November 10th) two days later. The patient returned home and I did not see him again. From Mr. Mahler and from Dr. Janeway, with whom the patient's physician communicated, I learned that the head-sling did no good, that it had been abandoned, that the patient was trying the support of a chair on the principle of a barber's chair, and that he was growing worse. Mr. Mahler spoke with me about visiting the patient at his home, but I could see no good that I could do by the visit.

The remainder of the history is from notes furnished by Dr. Stimson.

The spasms being violent, and increasing, the patient was obliged to rely upon morphia, only large doses procuring relief. He seized the pillow or sheet between his teeth, to prevent spasm, so constantly that his teeth were loosened and drawn to one side. The patient tried other methods, apparently extravagant, to control the spasms.

On or about the 10th of May, 1880, Dr. Stimson, assisted by Dr. Brownson, of New Canaan, and Dr. F. S. Gould, of New York city, performed an operation, with a view of preventing the twitching of the head.

The patient needed but little ether, since he was continually under the influence of morphia. An incision was made about one-half an inch to the left of the mesial line, and parallel to it, and about four inches long, and carried down to the laminæ. The cutis and areolar tissue were excessively hypertrophied, probably on account of the previous irritation (carbuncles, blisters, and hypodermic injections), and was not far from one and one-fourth inch in thickness. The obliquus inferior, and the rectus capitis posticus major were reached after no little difficulty, and found to be extremely enlarged. Their attachments to the spinous process of the axis were broken up, and three-fourths of an inch of the second cervical nerve (of left side) was removed. During the course of the operation the patient ceased to breathe on account of the combined effects of morphia and ether, and only very vigorous treatment re-established respiration.

The operation did not accomplish the purpose intended, for when the patient came out from the effects of the ether, the twitching recommenced. The next day Dr. Brownson divided the complexus and the splenius, under the impression that this would prevent the twitching. This proved to be futile. Although the operation was extensive, it was attended with little hemorrhage. Three ligatures were applied to small vessels. The patient died three days later from exhaustion.

The autopsy, made forty-eight hours after death, in the presence of Dr. Brownson and Dr. Allan McL. Hamilton, showed areolar hyperplasia, the condition of the vertebræ exhibited in the specimen, which shows the atlas dislocated forward and slightly downward in such a way that the left side of the atlas is slightly lower than the other, and the tubercle is slightly rotated to the right. On the left side the lip of the superior articulating surface is a little lower and more prominent than that of the right side, but not more so than may be a normal difference. The odontoid process has been fractured and is displaced forward and to the right with the atlas. The bodies have not been sawn through, but externally no appearance of caries exists. The depression felt during life in the pharynx was caused by overriding of the atlas; the bottom of the depression corresponding to the body of the axis. No actual depression existed.

Dr. Stimson adds: "My diagnosis, as given to Dr. Brownson, was pachymeningitis from extension of inflammation from without inward to coverings of the cord. I had no idea of fracture of the odontoid process, although I thought some other portion of the bones might have been injured at the time of the last fall, *i.e.*, that from the apple-tree."

Dr. Yale then added the history of one more case, which he did not see, but in which I was interested by Dr. Gibney's account of it during life. Dr. Gibney has been kind enough to place the notes of the case at his disposal, and he, therefore, presented so much of them as bore upon the cervical disease.

Case III.—J. J. B——, aged thirteen years. The patient had been in the Hospital for Ruptured and Crippled since October 21, 1875, and under treatment for infantile paralysis.

January 19, 1880.—For at least a week has had a stiff neck, thought to have come from a cold. Later it was discovered that a week before the appearance of the symptoms he had fallen backward, striking his head against the floor with considerable force. Liniments ineffectual. No infiltration; tenderness along ligamentum nuchæ; blister to nape.

January 21st.—No relief from blister. Ergot, ʒ ss. t.i.d. No appreciable rise in temperature; pulse and respiration normal. Keeps bed simply from difficulty of holding head erect.

January 22d.—Ergot not retained.

January 26th.—Still unrelieved. In fact, there now appears to be a subacute cellulitis, probably involving the cervical fascia. No enlargement of vertebræ to be felt in the fauces, and no prominence to be felt posteriorly, and, indeed, a careful examination fails to detect any vertebral disease.

January 28th.—Belladonna lotion. Ergot again, not borne, followed by a blister.

On February 8th the entry is continued: "No material change. . . . . Can this be a case of pachymeningitis cervicalis hypertrophica, with extension of disease along nerve-sheaths, causing a peri-pachymeningitis, or is it simply a rheumatic form of an inflammation affecting cervical fascia?"

February 9th.—On right side, just back of mastoid process, is a tumor barely perceptible.

February 10th.—Spinal brace and head-spring applied.

February 11th.—Out of bed.

February 15th.—Gets much support from head-spring, but dislikes the body brace very much. Tumor enlarging slowly. Some tenderness.

March 30th.—Incision made an inch deep before pus is reached. Tent and poultice. Temperature, P.M., 103°.

March 31st, A.M.—Attempt made to enlarge opening. A branch of occipital artery (probably priceps cervicus) was divided. ʒ ss. of blood lost. Compress. Brandy. Temperature, P.M., 103°.

April 2d.—Discharge very slight. He suffers so much that he begs to sleep in his rolling-chair, the pain on lying down being excessive.

April 5th.—A probe inserted fully two inches into the sinus touches bare bone. Parts kept open by passing probe three times daily. Complains of great pain in left side of neck, but nothing more than glandular enlargement can be seen there.

April 9th.—Pain so great as to require the constant application of iced cloths. Patient dislikes morphia. Potassium bromide forty grains used instead.

April 11th.—Delirium due apparently to anæmia. Discharge freer. Looks better in every way.

April 17th.—Hot fomentations used in place of poultices. Complains of difficulty in breathing, of soreness of throat, and for a week or two has been unable to take solid food. Takes liquid with a tube. Breathes heavily in his sleep.

April 19th.—Complains this morning of being unable to breathe through his nose. Examination shows a post-pharyngeal abscess. Incision with a bistoury, about ʒ ij. of pus evacuated. Pus thick, and toward the end about ʒ j. of caseous material like bone detritus flows out. Parts washed with carbolic solution. Immediate relief of dyspnœa.

April 22d.—Tumor near mastoid not discharging to-day, and is much smaller. Fomentations left off. By 10 P.M. it had increased in size, was red and painful.

May 2d.—No poultices for two or three days. Discharge not very great, but neck is just as tender as before. Emaciation continues. Still sleeps in rolling-chair in sitting posture.

May 3d.—Brace fits badly, and boy appears to sit uncomfortably. He leans to the right side nearly all the time, and occasionally backward. Boy, much against his will, was accordingly put to bed and all apparatus removed. No excoriations caused by brace. As he is turned to the left side of the bed he screams and the agony is so great that the eyes seem to start from their sockets. The helpless condition of the limbs is very notable, the left lower one hangs perfectly limp, seemingly devoid of all vitality, and the right is very little better. Discharge from the pharynx very slight, though the sac seems a little distended. After a while boy found an easy position, and lay with little suffering all day.

4 P.M.—Nurse reports speech difficult. He lost strength and then rallied.

5 P.M.—Became deathly pale, the respiration suddenly ceased. On reaching his bed found life nearly extinct. He was lying on his back, chin on sternum. After a few pulse-beats and gasps he died. After death, finger in pharynx found sac of abscess empty and glottis clear.

Autopsy, twenty hours after death, Dr. Janeway, superintending. Present: Dr. Poore and house staff. Thorax and abdomen not examined.

Spinal column exposed by sawing through the processes and exposing canal throughout its whole length. The cord carefully removed. No evidence found at any point of meningitis, acute or chronic; no tubercles; in the upper portion of the cervical region anteriorly the dura was a little thickened externally, which Dr. J. explained as an old pachymeningitis externa. Sections of the cord were made in the lumbar enlargement, and all that could be seen, macroscopically, was a cloudiness of the gray horns anteriorly and a diminution of these and, apparently to a slight degree, of the whole lumbar cord. No very marked changes, however, were discovered. The cephalo-rachidian fluid normal in quantity and appearance.

Bodies of the vertebræ were carefully examined from behind, and no evidence of caries found. As the mastoid abscess was enlarged and explored by the finger there could be distinctly felt one or two bits of roughened bone, probably separated by sav and chisel. The condyles of the occiput were fel bare and eroded.

On opening the calvarium the dura was found ver firmly adherent. In removing the brain nothing abnormal was found until the medulla was reached Against its anterior surface, just below the decussation, a bony process was found projecting, whic proved to be the odontoid. After the removal of th brain quite a depression could be recognized in th medulla at the point named. On flexing the hea upon the spine the odontoid could be plainly see to move backward and forward. On inserting th finger through the foramen magnum there could b felt toward the right side a small bit of eroded bone decided to be the insertion of the check ligaments both these and the transverse ligament being to al appearance separated from their attachments by disease of the bones at their insertion, thus allowin the displacement described. The mastoid proces seemed to be normal.

The condition, then, was one of caries of the occipito-atloid articulation and of the body and odontoid process of the axis. Both the pharyngeal an the external occipital abscess were dependent upo the caries.

FRACTURE OF THE EPITROCHLEA (INTERNAL CONDYL OF THE HUMERUS).

Dr. L. A. Stimson narrated a case as follows: boy, eleven years of age, while sitting astride of fence, fell upon the right side and, as he said "caught his arm under him." Within half an hou from the time of the occurrence of the accident he entered the hospital, and it was stated by the attendant that he had dislocation backward of both bones of th forearm. After the dislocation was reduced, it wa noticed that on the inner side a piece of the humeru was loose, and diagnosis of epitrochlean fractur was made. On the next day, when he saw him fo the first time, there was no swelling, no ecchymosis the movements of the forearm upon the arm wer almost perfectly free, and there was no pain. small fragment of bone, however, could be graspe between the thumb and fingers on the inner side o the arm, and it could be moved forward, backward upward, and downward, with slight crepitus, whic was not distinctly bony in character. On the following day the patient was seen by two members o this society, and on the day following that, the elbo in the meantime being kept in a right-angle splint there were some blebs upon the inner side of th arm and elbow, there was considerable swelling, an the limb was quite painful. A lead and opium was was applied, the swelling diminished, and on Monday the boy was seen by another member of thi society. Dr. Stimson thought that there had undoubtedly been fracture of a portion of the bon involving the epitrochlea; and he further said tha Dr. Frank H. Hamilton stated very positively tha he could feel distinctly that a fracture followed th line of the conjugal cartilage of the epicondyle, at leas its upper portion, and therefore had no questio that it was a pure fracture of the epicondyle. Dr Stimson was not able to make out those points i diagnosis, and limited his statement to fracture of small portion of bone, perhaps one-third of an inc in diameter, upon the inner side of the condyle o the humerus. The piece was distinctly movable and the injury did not seem to involve the joint a all. In other words, he regarded it as an extra articular fracture, occupying the seat of the epitrochlea.

Dr. Markoe remarked that he examined the patient's elbow with a great deal of care, but it was when the parts were considerably swollen and tender, and he did not feel that he was entitled to speak positively with reference to a diagnosis. He, however, noticed that the lateral motion between the forearm and arm was greater than it should be if the internal condyle was entirely intact. The arm being held firmly, he made motion backward and forward, and he thought that he could move the internal condyle. Although not entitled to speak positively, he inclined to the opinion that the fracture involved the joint.

The President stated that he had an opportunity to examine the boy's elbow before there was very much swelling, and had no doubt whatever as to the existence of fracture of a very small, button-shaped piece of bone which was altogether outside and internal to the articulation. The piece was distinctly movable, and crepitus was distinct, but not bony. He did not make lateral movements of the joint, but such movements as he did make seemed to show that the articulation was unaffected. He thought that there could be no clearer evidence, clinically, of such a fracture than was offered in the present case. He was unable to conceive that it could be anything else than a fracture of the epicondyle.

Dr. L. A. Stimson remarked that in looking over the recorded cases he had been struck by the fact that in several of them there was simultaneous dislocation at the elbow-joint. In the case just reported, the house surgeon stated that he reduced the apparent dislocation by simply drawing upon the forearm, and that it was accompanied by no sound or jar similar to that which is usually found on reducing a dislocation. [A recent examination of the case gives reason to believe that there was partial separation of the epiphysis with angular displacement backward.] In all the recorded cases the injury was produced by a fall upon the palm of the hand.

Taking into account the difficulty of explaining how fracture of the internal epicondyle could be produced by that force, especially in children whose muscles are weak, it had seemed to him that a possible explanation might be found in the fact that the fracture might not be confined to the internal epicondyle, but might involve also a portion of the epiphysis corresponding to the ulna, and that when the epiphysis was torn off by the fall upon the hand, the muscular force might be sufficient to break off the internal epicondyle, which was attached only by a limited surface. That would also explain the prolongation of convalescence, and the stiffness and temporary general anchylosis which had resulted in one or two cases.

EMPYEMA TREATED WITH THROUGH-DRAINAGE.

Dr. T. M. Markoe narrated a case as follows: he was called in consultation to see a patient who had a history of having had, during five months preceding, three distinct attacks of pleurisy, from each of which he had partially recovered, but each had left him in a feeble state of health, with considerable soreness on the side, and evidently his pleuritic trouble not entirely eradicated. Gradually the lower part of the left side of the thorax became enlarged, and the symptoms seemed to point to accumulation of pus in that region. His constitutional symptoms were marked: high temperature, sweating, etc. An exploring-needle was introduced to a depth of three inches, but no pus was found, and no satisfactory relief was given. After the lapse of two or three weeks, during which time the patient's general condition deteriorated considerably, another exploration was made with an aspirating-needle, which was introduced in nearly the same place as was the first needle, namely, between the ninth and the tenth ribs, well back, and in the central portion of the general fulness, and this time pus was encountered and several ounces were withdrawn. The matter ceased to flow, and it was supposed that the abscess had been evacuated. The general condition of the patient, however, continued to deteriorate, and the encroachment of the tumefaction upon the abdominal cavity became more and more marked, and then Dr. Markoe saw him for the first time. He found a swelling extending well forward, tender, and, in the dorsal region, just at the outer edge of the quadratus lumborum; there was marked fluctuation. There was also a fluctuating spot in the anterior aspect of the chest at the level of the junction of the fifth or sixth ribs with the sternum, and he satisfied himself that the wave of fluctuation could be transmitted from before backward so that it could be felt in the loins. Dr. Markoe made an opening into the tumor in the lumbar region and let out two quarts of extremely fetid pus, and as it flowed away the prominence on the anterior aspect of the chest became more and more flaccid, and finally disappeared. He then introduced a long, leaden probe, pushed it carefully forward, doing as little violence as possible, and finally succeeded in causing the end of it to make an impression on the flaccid wall, when fluctuation was felt anteriorly. An opening was then made and a drainage-tube introduced, and the case was subsequently treated upon the plan of *through-drainage*—the plan of treatment originally suggested for this precise condition by Chassaignac. The cavity was first syringed with warm water, then slightly carbolized water from one to two per cent., never above two and a half per cent., and at no time using it very freely.

The effect of the operation was somewhat depressing, but within a few hours he rallied, his temperature soon fell from 103° to 100 F., and from that time on it had not again risen. There was no inflammatory reaction. The injections were continued. An abscess had since formed in the lumbar region, but it was evidently extra-thoracic, and after a time ceased to discharge. At present the general condition of the boy was greatly improved. He had spent some weeks in the country. Only a few drops of pus are now discharged, and only a few drops of fluid can be thrown into the cavities, and he seems in a fair way to recover. He heard from him last about the end of September, three months after through-drainage was established.

[At the next meeting of the Society Dr. Markoe added that he had examined Chassaignac's description of the method, which was very explicit, and consists in introducing the trocar between the sixth and seventh ribs, then turning it forward and bringing it out again at the distance of two fingers, and leaving the drainage-tube hanging from these openings. He thought that operation was very different from the procedure which he adopted where the drainage-tube traversed the entire pleural cavity, from one opening to the other.]

Dr. L. A. Stimson mentioned a case in which an abscess occupied a similar region, was very large, discharging more than a quart, and its contents were very fetid. He treated it by making a single opening in the loin, and without antiseptic injections. The cure was rapid and satisfactory. He refrained from injecting the cavity of the abscess in that case because of the termination of a case that had come to his knowledge, in which an abscess in the iliac fossa was evacuated, and then injected with a carbolic solution, and the patient died within two hours, with symptoms indicating carbolic acid poisoning.

Dr. Markoe thought that an essential feature of this plan of treatment was to secure not only free evacuation of the pus, but also of the fluid used in the injection. He would not be willing to inject a large empyemic cavity with carbolic acid solution, for fear of accident.

Dr. Yale referred to a case in which a simple large abscess of the thigh was hyperdistended with carbolized water, and the operation was followed by collapse, nearly complete suppression of urine and other alarming symptoms, and the patient's life was saved only by the most active exertions.

Dr. G. A. Peters alluded to a case in which he proposed to hyperdistend an abscess of the thigh with carbolized water, but the opinion given by several gentlemen was so decidedly against it that he abandoned the method.

Dr. Erskine Mason spoke of a case which occurred in Prof. Post's clinic, where an abscess was distended with carbolized water, and the operation was followed quickly by alarming symptoms, but the boy finally recovered.

With reference to injecting the pleural cavity, some years ago he made a free opening into a patient's chest in Roosevelt Hospital, and removed fifty-six ounces of fetid pus. The cavity was then washed out with a weak solution of salicylic acid, and at once the discharge was deodorized. He had done the same thing repeatedly since, using a solution of salicylic acid, 1 to 100, without bad effects. The man upon whom he used it first remained in the hospital for some time, but finally recovered. His chest was irrigated daily.

PROBABLE TWISTING OF INTESTINE.

Dr. L. M. Yale narrated a case which he saw in consultation with Dr. J. W. Pinkham, of Mt. Clair, N. J. It had the following history: A man, aged twenty-three years, had diarrhœa on a Tuesday and Wednesday, and on Wednesday night he summoned a physician who, from the severity of the pain, diagnosticated probable intestinal obstruction. On the day following the patient's symptoms were so much improved that he doubted the value of the diagnosis, but on Friday the symptoms returned with increased severity, yet did not seem urgent enough to warrant interference. The symptoms were constipation, vomiting of coffee-colored fetid material in excess of the quantity of liquids ingested, and frequent going to stool, particularly after enemas which were not followed by fecal evacuations, but by discharge more or less of blood. No tumor was recognized in the abdomen, none in the rectum. The next day the general condition of the patient seemed better, but on the day following that all the serious symptoms were again present. A more complete exploration was then made, and Dr. Berry introduced his hand into the rectum as high as the sigmoid flexure, and no tumor was recognized. On coming out from under the influence of the anæsthetic, the patient had a violent attack of pain, but it was spontaneously relieved. No further pain ensued. The patient's bowels began to move freely, and he made a rapid recovery. The symptoms were persistent constipation, vomiting o fetid, coffee-colored material, bloody discharges, pai localized, in a general way, in the lower part of the abdomen, but not always precisely in the same spot and the points at which tympanitic percussion or dulness existed were not always the same. The explanation which Dr. Yale gave of the symptoms was that there had been a twist of the intestine withou intussusception, and that the manipulation during the exploration had replaced it and caused a cure.

The President thought it quite probable that i was a case of twisting rather than intussusception He also mentioned a case on record, of reduction o intussusception by the introduction of the hand into the rectum.

MODE OF EXTIRPATING THE MAMMARY GLAND.

Dr. Lange presented a breast with its attachments, that illustrates a particular method of amputation. The essential point was extirpation of the breast, together with the fatty and glandular contents of the axilla, *in one piece*, including all the connective tissue between the borders of the pectoralis and the latissimus dorsi muscles, in order to include all the lymphatics which are in a state of carcinomatous degeneration.

Dr. R. F. Weir remarked that in a number of instances he had noticed a chain of lymphatics running across the pectoral muscle, forward from the axilla and reaching nearly to the sterno-clavicular articulation.

Dr. Peters said that he had noticed the same condition mentioned by Dr. Weir.

The Society then adjourned.

Correspondence.

THE TOXIC ACTION OF ERGOT.

To the Editor of The Medical Record.

Sir—In the Medical Record for October 23d, page 473, Dr. S. D. Radcliffe, of Washington, D. C., refers to a communication of mine that gave to your readers the details of a case whose symptoms I attributed to the toxic action of ergot. I will not take up your valuable space with a recital of the points that formed my diagnosis. Suffice it to say that I still believe the case to have been one of ergotism, the symptoms not merely due to loss of blood. Ergot is given by many in large doses—I believe even much larger ones than spoken of by Dr. Radcliffe, without bad effects (especially in uterine tumors, etc.); at the same time I do not see why we cannot occasionally meet with a case where intolerance to its action may exist to the same degree we often find present in connection with the use of other powerful drugs, as opium, cinchona, etc. I presume my case was one of these. Small, though often-repeated doses, given to a case where absorption is probably unusually rapid from bleeding, or the system susceptible either from prostration or inherent qualities, may, at times, be followed by alarming results, and as my case was one of these, I reported it as a warning.

In a series of experiments upon animals with the various preparations of ergotine,* the toxic symptoms were analogous to those witnessed in my patient. That ergot is a powerful and dangerous drug, no one, I think, will deny, and I earnestly hope that my few remarks will bring out the expression of the opinion of many who use ergot in large doses.

* Alumni prize thesis, University of Pennsylvania, 1873: "Physiological Action of Ergot."

Very respectfully yours,
JOHN M. KEATING, M.D.

PHILADELPHIA, October 29, 1880.

MEDICAL LAW IN WYOMING.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR—Allow me to correct an error in your editorial, "Medicine in the United States as Others see it," of the 16th inst. After quoting Dr. Hardwick as to the states having no medical laws whatever, you say, "In addition to these [names of states] must be included the District of Columbia and all the territories." The error consists in including Wyoming Territory, for we have a most excellent statute law, entitled, "An act to prevent the practice of medicine, surgery, or obstetrics by unqualified persons." As the law is too long for your columns, I will give the principal features.

Only graduates of chartered medical schools are allowed to practise, and, as proof, every physician is required to file a copy of his or her diploma, for record, with the registrar of deeds of the county in which he or she proposes to practise, exhibiting the original, and making an affidavit that he or she is the identical person named in said diploma. The penalty for a violation is a fine of from fifty to five hundred dollars, and imprisonment from thirty days to six months in the county jail. It is further made the duty of the police, sheriff, or constable to arrest all persons violating this act.

From the fact that there is not a single unqualified practitioner of medicine in the territory at present, we believe the law is all that can be desired.

Yours respectfully,
J. H. FINFROCK, M.D.

LARAMIE CITY, WYO., October 27, 1880.

SOME OF THE MEDICAL HISTORY OF GREAT BRITAIN.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR—*In re* your editorial of October 16th on "Medicine in the United States as Others see it," Dr. Hardwicke might have learned a useful lesson had he studied the medical history of Great Britain from 1806 to 1826. During this time the trade of granting degrees in physic by the Scottish universities was carried to such an extent that a royal commission was appointed to inquire into the general state of the Scottish universities. This commission "was astonished at the small increase of students compared with the large increase of graduates" during this time. The report of this commission goes on to state: "It does appear quite unreasonable that when there are belonging to the university a number of professors, who must be supposed equally skilled in medical science, there should be a monopoly of examinations to a particular part of them, apparently for no other purpose than that the persons so favored may receive the addition to their emoluments arising from the fees paid to the examiners." The universities of Edinburgh, St. Andrew's, and Aberdeen were alike guilty, and in this course the University of Edinburgh was upheld by the College of Surgeons of Edinburgh. St. Andrew's, however, in the end prevailed in "destroying this most odious monopoly that ever disgraced British legislation." So will it be here in time. The time is coming when the state, or better still, the American Medical Society, will have a voice in saying who shall and who shall not receive the honorable title of "Doctor in Medicine."

Those wishing to pursue this matter further might consult the report of His Majesty's commission on the state of the Scottish universities from 1806 to 1826, or the preface to "McIntosh's Practice of Physic" (2d Am. ed., 1837).

Respectfully yours,
M. A. MCCLELLAND, M.D.

KNOXVILLE, ILL.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from October 31 to November 6, 1880.

MEACHAM, F., Capt. and Asst. Surgeon. Granted leave of absence for one month. S. O. 234, A. G. O., October 30, 1880.

PATZKI, J. H., Capt. and Asst. Surgeon. Assigned to duty at Jackson Barracks, La. S. O. 126, Department of the South, October 29, 1880.

HEIZMANN, CHAS. L., Capt. and Asst. Surgeon. The extension of his leave of absence of September 28, 1880, from Headquarters, Division of the Pacific and Department of California, is further extended two months. S. O. 234, C. S., A. G. O.

LAUDERDALE, J. V., Capt. and Asst. Surgeon. Relieved from duty as Post Surgeon at Newport Barracks, Ky., and assigned to duty at McPherson Barracks, Ga. S. O. 127, Department of the South, November 1, 1880.

Medical Items and News.

CONTAGIOUS DISEASES — WEEKLY STATEMENT. — Comparative statement of cases of contagious diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending November 6, 1880.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro spinal Meningitis.	Measles.	Diphtheria.	Small-pox.	Yellow Fever.
Oct. 30, 1880.	0	19	66	5	5	98	3	0
Nov. 6, 1880.	0	18	100	2	13	83	1	0

LEECHES.—From five to six million leeches, costing a million and a half of francs, were raised in France during the eight years ending in 1836. One hundred and eighty-seven thousand pounds of blood were drawn annually during this same period.

TRICHINÆ IN RELATION TO THE PUBLIC HEALTH. By F. S. BILLINGS, M.V.—We have already commended this advisable monograph in a review of the Annual Report of the Massachusetts State Board of Health. With the inference from Dr. Billings' statistics that there are nearly 4,000,000 trichinous hogs in this country, the importance of scientific study, as well as of public supervision of the matter, must appear very great.

CONSTITUTIONAL DISEASES AND EYE TROUBLES.—Dr. D. B. St. John Roosa writes: "Dr. George S. Stevens, in the last number of the RECORD, states 'that the advice which Dr. Roosa represents me as having given was never rendered by me in this case.' From a note received from the doctor I learn that the case referred to is the one of Miss P., quoted in full in my lecture on the Cure of Constitutional Diseases by the Use of Glasses. In answer to this I have to state that the father of the patient, a physician, writes me as follows, in a note dated October 14th: 'I informed you that she had been under Dr. Stevens' care for some time; that she had been in Albany for several weeks, and that the doctor had exercised the muscles of the eye; that she had improved somewhat, but that her headaches had continued about the same as before the treatment commenced. Then Dr. Stevens proposed the same operation that he had performed on her cousin. I understood this to be partial tenotomy of internal rectus of one eye.'

"An oculist of this city, who knows the case and has talked with Dr. Stevens about it, tells me that Dr. Stevens said to him that he had recommended an operation on one of the recti muscles in this case. I think I have now cleared myself of the charge of basing my criticism upon 'supposed advice' of which I am 'only informed by rumor.'"

A NEW DEPARTURE IN TEACHING THERAPEUTICS has been introduced by Dr. Bartholow, at Jefferson Medical College. A laboratory has been fitted up, and the students are taught practically how to manipulate drugs and how to pursue experimental therapeutics.

STATISTICS RELATING TO MEDICAL EDUCATION OF WOMEN IN RUSSIA.—From the article of Dr. Hertzenstein in *Vratch*, 1880, No. 34 and 35, we learn that the St. Petersburg school of medicine was opened to women in 1872. During eight years 796 students matriculated. Under 22 years old were 72 per cent.; between 22 and 30, 24 per cent; above 30, 3 per cent. According to social condition they are classified: single, 89.4 per cent.; married, 9 per cent.; widows, 1.6 per cent.

As the course of studies is five years, only the first three classes had graduates; their number is 111, corresponding to 266 matriculates. During 1879 453 students pursued the study of medicine, and as 111 graduated and 30 died, 202, or 25 per cent., abandoned their studies. This large percentage is due to the fact that the majority of students are obliged, while studying, to earn their living by giving lessons, literary work, etc., a condition not favorable for a steady study of five years.

THE LIBRARY OF THE PHYSICIANS TO THE GERMAN HOSPITAL AND DISPENSARY OF THE CITY OF NEW YORK, which is located at the Dispensary Building, No. 65 St. Mark's Place (East 8th St., bet. 1st and 2d Aves.), contains nearly 8,000 volumes of German, English, and French periodicals, the series of which are constantly being completed. Having been put in perfect order, and a printed catalogue having been published last spring by the present librarian, Dr. Hermann G. Klotz, the library is now open to the medical profession. Those wishing to avail themselves of its advantages may apply to any member of the medical staff of the hospital or dispensary, except the librarian, for letters of introduction, upon which the librarian will issue, free of charge, tickets of admission, good for one year from date, which entitle the holder to visit the reading-room as well as to borrow books. The reading-room, where all the new journals, as soon as practicable after arrival, will be on file for at least one week before going into circulation, is open from 2 to 5 o'clock, Sundays and holidays excepted. Those wishing to borrow books must apply either personally or in writing to the librarian on Mondays, Wednesdays, and Fridays, from 4 to 5 o'clock (except in July and August), and sign their name and residence to blanks furnished for this purpose, a single blank to be used for each volume. Books ordered by letter may be obtained from the janitor of the dispensary after 5 o'clock, on delivery of receipts. Time allowed for keeping books not over two months. Catalogues at twenty-five cents are sold by the janitor.

CASES SHOWING THE IDIOPATHIC ORIGIN OF DEEP ABSCESSES.—We have received an interesting letter from Dr. J. P. Creveling, of Auburn, N. Y., in which three cases of deep abscess are related, the cause in each instance being non-traumatic. Dr. Creveling refers to the statement made by Dr. L. A. Sayre, at the last meeting of the State Medical Society, to the effect that it is doubtful whether deep abscesses ever occur with local injury. As evidence against this opinion the present cases are reported. The first patient, a young man of eighteen, had a scrofulous history. He had been suffering from general debility for several months. At length, swelling and pain appeared in the abdominal wall, an abscess developed and burst near the umbilicus. It burrowed down toward the left side of the pubes. It was between the abdominal muscles and the peritoneum. Three incisions and drainage were employed, and in about two months after being put under treatment, and five months after the first symptoms appeared, the patient was well.

The second case was that of a woman, aged fifty-five, who had suffered from a lumbar abscess. When brought to the hospital she was nearly moribund, and she soon died. The abscess had existed for about six months, and was attributed to a "cold." There was no history of traumatism.

The third case was that of a young woman, aged twenty-two, who gave a malarial and scrofulous history. She was first seen last April, when she was found to be suffering from debility and chronic diarrhœa. She also complained of soreness round the left side of the pelvis. She was seen again four months later, and was then found to be suffering with a large abscess in the left inguinal region, and another smaller one near the last lumbar vertebra. There had been no injury received. Under proper surgical treatment she recovered.

Dr. Creveling believes that these cases show very positively that deep abscesses can occur without traumatism.

A TÆNIA "IN SITU."—M. Laboulbène, in making the autopsy on a man who had died suddenly from the rupture of the pulmonary artery, was afforded the opportunity of studying a tænia "in situ." Nothing was found in the stomach or the duodenum of the subject. When the jejunum was reached, he found a tænia folded upon itself, and occupying a space of forty-eight centimetres (about a foot and a half). The head was directed superiorly. The worm was still living, thirty-three hours after the death of the patient. Several living cucurbita were seen. The tape-worm measured 412 centimetres in length. —Cor. of *Monthly Review*.

Original Lectures.

ON THE
PHYSIOLOGICAL ANTAGONISM BETWEEN MEDICINES, AND BETWEEN REMEDIES AND DISEASES.*

By ROBERTS BARTHOLOW, M.D.,

PROFESSOR OF MATERIA MEDICA AND THERAPEUTICS IN THE JEFFERSON MEDICAL COLLEGE, PHILADELPHIA.

(Special Report for The Medical Record.)

Lecture I.

GENERAL INTRODUCTION—THE PHYSIOLOGICAL ANTAGONISM BETWEEN OPIUM AND BELLADONNA.

Mr. President and Gentlemen—In this country private beneficence, although vast in its generous outlays, is seldom devoted to purely medical objects. It, therefore, behooves us to honor the memory of the founder of the Cartwright lectureship. In this gift, so rare and admirable in its provisions, the medical profession is offered an opportunity for honorable distinction; while it is replete with benefits not less to the founder than to the profession. By this means his benefactions are especially celebrated annually, and he is enrolled for all future time among the philanthropists who really benefit their fellow-men.

I cannot be insensible to the very high honor of having been selected to deliver the first course of these lectures; but I do not conceal from myself the difficulties and obligations of the position. In the Gulstonian, Lumlian, and other lecture courses which have done such good work in England, it is customary to expect that new facts, new truths, and new discoveries will be set forth; and brought into comparison with such admirable efforts, I can but feel how humble are the attempts to which I am to ask your attention. After careful consideration, however, I have selected a topic which has a strong interest at the present day, and to which I have been able of late to add some few new facts.

My subject is, the Physiological Antagonism between Medicines, and between Remedies and Diseases; and this antagonism or opposition of action may exist throughout the whole range of the relations of such agents, or it may be limited to a few points only. There are, however, few, if any, in which the antagonism is universal. The popular view of the doctrine of antagonisms in the profession is an opposition of action of poisonous medicinal agents, by which the effects produced by one are counteracted and rendered void by those of the other. A dose of one may thus be completely antagonized by a dose of the other. This conception of physiological antagonism is exaggerated; for such a perfect antagonism is as rare as exact similitude. It has been proposed by some to substitute the word antidotism for antagonism; but this implies a chemical, rather than a physiological action. Physiological antagonism means simply a balance of opposing agents.

Some such conception as our modern doctrine of physiological antagonism has existed from the remotest times, as is evident from some of the aphorisms of Hippocrates. Thus, he speaks of repletion being counteracted by depletion, and says that diseases are cured by their contraries. In another aphorism he says that some diseases are cured by contraries, and some by similar remedies. On this was founded the well-known criticism of Carus in his controversy with Hahnemann: "Whatever is new in homœopathy is not true, and whatever is true in it is not new." The doctrine of contraries was held by Theophrastus, and many others who succeeded Hippocrates; but it was opposed by some of the most distinguished of the Alexandrian school. Galen, however, was essentially a trimmer, and he "claimed to create a science of medicine in which every practical precept was deduced from some pre-established principle." But the only rational expedient in medicine applicable at that time was the doctrine of contraries, which controlled the practice of the whole profession until the sixteenth century. Fernel, the teacher of Vesalius, wrote an elaborate treatise in which he contended that every disease must be controlled by contraries. Some claimed, he stated, that certain diseases were cured by similars; but this *modus operandi* was only apparent, and not real, since remedies, which appeared to act in this way, in fact destroyed the disease by removing its cause.

This ingenious attempt of Fernel, however, could not prevent the final overthrow of the doctrine of contraries, and when Paracelsus burned the works of Galen and Avicenna, it vanished away in their smoke. After the discovery of the circulation of the blood many new theories were advanced, and the systems of Stahl, Brown, Rasori, and others necessarily attracted the attention of the profession. Then arose that eccentric and mystical enthusiast, Hahnemann, imbued with the fanciful ideas of Mesmer. Before the period of his senility, which was especially characterized by his spiritualistic tendencies, the law of similars propounded by him was merely a statement of the views of Hippocrates, to which allusion has already been made. Both the law of contraries and the law of similars were stated by Hippocrates, as we have seen. Hahnemann claimed that the disturbance in the functions caused by a drug must interfere with the course of a disease; there thus being two forces acting on the same tissues or organs.

The great epoch of modern physiological investigation was inaugurated by Bichat, and his discoveries were of vast importance. When he came on the stage, therapeutics were in a truly chaotic condition; there being no settled principles whatever which constituted reliable guides for practice. Some, he said, considered materia medica, of all sciences, that which showed to the fullest extent the contradictions of the human mind; but, for his part, he did not think it a science at all. "It is said," he continued, "that the practice of medicine is repulsive. I go farther. I hold that it is impracticable in the present state of our therapeutics." When Bichat, the founder of modern physiology, died, in 1802, Magendie was passing through his course of studies. Thoroughly imbued with the teachings of Bichat, he pursued investigations of similar character with great enthusiasm and success, and was the first to engage in a scientific physiological and therapeutical research. The subject of this was upon poisoning, and such an experimental investigation was only possible after the functions of the spinal nerves had been determined. He next pursued a brilliant series of experiments in regard to the new alkaloid, strychnia, and the result of this was the discovery of the first physiological antagonism, that between strychnia and paralysis. Many have supposed that the first use of this agent in the treatment of paralysis was entirely empirical; but this was not the case. It was prescribed with a definite and scientific view after Magendie had pointed out its exact physiological action, and the result proved how correct were the deductions concerning its therapeutic value which he based upon this.

---

* Cartwright lectures of the Alumni Association of the College of Physicians and Surgeons, New York. Course of 1880. Delivered Tuesday evening, November 9, 1880.

Having now advanced thus far, let us take up some special instances of physiological antagonism. As early as 1570 Pena and De Lobel published an account of the counteraction of the effect of belladonna berries by means of theriaca, a preparation of opium. Afterward theriaca was reported as a powerful antidote for poisons of all sorts; but later experience proved that it was for belladonna. By the beginning of the nineteenth century sufficient facts had accumulated to demonstrate the indisputable antagonism between belladonna and opium, and since then the evidence has been still more abundant and conclusive. In the year 1810 Joseph Lipp, and in 1855 Dr. Thomas Anderson, showed how the toxic effects of belladonna were overcome by the use of opium; the dilatation of the pupils which had been produced by the former at once disappearing. In July, 1859, Benjamin Bell, of Edinburgh, published a case of poisoning by atropia successfully treated with opium. In January, 1862, Dr. C. C. Lee published in Philadelphia the report of two cases, illustrating the antagonistic effects of the two drugs. The first was one of opium-poisoning, and the second one of belladonna-poisoning. In his paper Dr. Lee gave a *résumé* of the literature of the subject, and also entered with some detail into the history of the adverse experience of Brown-Sequard. Then Dr. William F. Norris, of Philadelphia, gave a complete tabulated sketch of every case, which he could possibly collect, that illustrated the antagonism between the drugs. In 1865 an admirable paper on the subject was published by Mitchell and Moorhouse, of Philadelphia, and since then the cases and papers had greatly multiplied.

The history of this subject is not complete, however, without some reference to the opinions and experiments of those opposing the view of such an antagonism. These authorities, it is well to know, have based their conclusions principally on experiments made upon animals. The most noted of them is Brown-Sequard, and he experimented upon guinea-pigs. Bois used cats for the purpose. Thus, to a cat he gave a dose of morphia almost but not quite sufficient to destroy life, and when the animal had entirely recovered from the effects of this he gave it a dose of atropia just short of producing death. Then when a sufficient time had elapsed to ensure complete recovery from that, he gave the cat the same doses of morphia and atropia together, and they proved fatal. Onsum, on the other hand, made his experiments on frogs; but whatever are the animals employed, or whatever the methods resorted to, the results were uniformly unfavorable to the existence of an antagonism between the two drugs. None of these experiments, however, were free from certain sources of error. Harley collected the largest number of facts, but his fundamental error was that he was willing to accept only those cases in which the antagonism extended throughout the whole range of effects.

Although the antagonism between opium and belladonna was the first to be discovered, these drugs do not by any means afford the only example of such physiological antagonism. There are, in fact, more perfect antagonisms than this, and such an instance is that between strychnia and disease. Magendie's experiments upon animals with this agent enabled him to suggest what its therapeutic effects would be, and Fouquier applied the suggestions successfully in practical medicine. Magendie said in advance that medicine would derive great benefit from an agent that was capable of producing certain special effects upon the spinal cord, and his opinion was afterward abundantly confirmed by the results of clinical experience. Could any fact more strikingly exhibit the benefit to be derived from physiological experiment?

Later followed the remarkable investigations of Claude Bernard, and the discovery of the physiological effects of woorara. This agent is essentially a paralyzer, and hence it is recommended in cases where spasm is to be overcome. Especially is it indicated in tetanus and hydrophobia, and experience with it thus far seems to show that it is the single remedy which has appeared to have a curative effect in the latter disease. Such discoveries ought certainly to have enough weight to silence forever the silly cavils of anti-vivisectionists.

Next we have the discovery of the antagonism between atropia and physostigma. In 1867 a single experiment was made by Bourneville in proof of this. He first gave a dose of calabar bean to a guinea-pig, and then followed it with a sufficient dose of atropia to counteract its effects. During that year I was engaged in making experiments in the same direction with a view to offering their results to the profession, in a paper to be presented in competition for the prize of the American Medical Association. This paper was published in 1869, and in it I distinctly asserted the existence of the antagonism. In the following year the remarkable paper of Thomas R. Frazer, of Edinburgh, appeared on the subject. In the meanwhile, Professor Preyer had published, in 1868, the first part of an elaborate treatise on prussic acid. In the second part, which appeared the following year, he contended that hydrocyanic acid and atropia were physiologically opposed to each other. That this was the case, however, was denied by a number of German authorities, and also by Hare and Keen, of Philadelphia, as well as by myself. In a second paper, more recently published, Professor Preyer pays his respects to us all, and proves to his own satisfaction, at least, that we are mistaken.

In 1869 Oscar Liebreich gave us chloral, and demonstrated its antagonism against strychnia. Noted results, in proof of this, were also obtained by the committee appointed by the British Medical Association, with J. Hughes Bennett at its head. The next year Dr. Fothergill, under the auspices of the British Medical Association, showed the antagonism between aconite and digitalis, and in 1877 Husemann's paper on the antagonism of chloral appeared. To such importance, then, has this subject attained, that no study of a medicinal agent is complete until its antagonisms have been determined. As we have seen, the doctrine of contraries was, for a very long period, the leading principle in the field of therapeutics, and it is evident that, even when this prevailed, many instances of antagonism must have been discovered by clinical experience.

(The lecturer then went on to show that the doctrine of physiological antagonisms found its counterpart in the mechanism of the functions of the brain and nervous system. Thus, in the brain, there were centres for the inhibition of reflex action, and reflex action was interfered with when coincident opposing impressions arrived from different points. In this way singultus might be checked by the application of a strong faradic current. In the medulla oblongata there was a centre of extreme sensibility, and above it a spasm centre; and if there were not this check upon the latter the most violent effects would be produced. Hence, the abnormal readiness to react when the influence of the cerebrum was withdrawn. In the same way the vascular tonus in the heart was maintained at the normal by the action of antagonistic influences.) The manner in which the cardiac action is affected by opposing influences, he continued, is admirably shown by the effect of cold and heat. If we place the heart of a turtle or a frog, freshly taken from the body of the animal, upon a metallic surface, and apply cold to the latter, we shall find that the organ gradually ceases to contract and dilate; but if we then apply heat in the same way, the heart-beats will at once be resumed. Again, if we drop upon the freshly-exposed heart of a frog a small quantity of serum, containing muscarin, the organ at once ceases to act, and apparent death is produced; but if we then drop upon the heart a little serum, containing two-tenths per cent. of atropia, it will begin to act again.

The reciprocity of action is a safeguard, and thus danger to the circulation is prevented by a quickening of the pulsations of the heart. A similar mechanism is found in the function of respiration, where the movements of inspiration and expiration are antagonistic, as well as in the control of the sphincters and other physiological phenomena.

We find also that the same principle obtains in the world of physics. I need hardly remind such an audience as this, that if two waves of light, of equal altitude, arriving from opposite directions, meet at half the distance of their respective elevations and depressions, so that the crest of one corresponds to the hollow of the other, both are obliterated, and the result is darkness; nor that if two equal waves of sound meet under similar circumstances, the result s silence. In the same way, when two bodies of equal weight and momentum come together, both are arrested at the point of impact. So, in electrici-y, when the positive and negative elements are equal, an exact equilibrium is maintained; and in chemis-ry, too, the great principle is the same. But why multiply examples, when nothing can possibly be more evident than that antagonisms exist everywhere?

I will now ask your attention more particularly to he physiological antagonism between opium and belladonna, and in what follows I shall use the terms opium and morphia and belladonna and atropia synonymously. In the investigation of any such supposed antagonism two inquiries present themselves: *first*, Does the antagonism exist? and *second*, What s its nature? Dr. Norris, of Philadelphia, in the paper before alluded to, presented to the profession he first complete tabulated statement of all the in-tances of the antagonistic action between the two drugs that had been recorded in clinical medicine up o the date of its publication. I have now added to his list all the cases that have appeared since that ime, as well as two others, occurring previously, which seem to have escaped the attention of Dr. Norris. One of these was published in 1854, by Lindsay, and the other, in 1855, by Dr. Sibson. The total number now on record is 120. Of these nly fifteen cases proved fatal, which is a percentage f 12.5 failures, a result which certainly indicates omething more than a *post hoc.* The antagonistic agents which were employed must undoubtedly have averted death; but at the same time it is also necessary to estimate the part that may have been played by other agents, such as emetics, the stomach-pump, coffee, flagellation, etc.

The history of the fatal cases is very instructive; for why should the antagonism fail? A number of elements must be taken into consideration in answering this question, and these can perhaps best be brought out by taking a rapid glance at the fifteen cases mentioned.

Case I.—This was reported by Ludwig Pollak in the *Wiener Presse.* The patient was sixty years of age, and four years before had had an apoplectic seizure. He took $\frac{36}{100}$ of a gramme, or about five grains, of atropia, with suicidal intent. The report states that a syringeful of morphia solution (strength not stated) was injected hypodermically, and that no apparent effect being produced by this, another dose, of half the quantity, was employed in the same way.

Commentary.—The condition of the brain in this case was undoubtedly very unfavorable for a recovery; but especially is the failure to be attributed to the inefficient method in which the morphia was administered. If we assume that the solution was of the usual strength and the syringe of the usual size, the amount could not have exceeded three grains altogether. The proper method to have pursued here would have been to inject one-quarter or one-half a grain of morphia every twenty minutes, until some pronounced effect had been produced upon the respiration and the pupils. The patient having had a cerebral lesion, however, there would of course have been less chance of a favorable result than if this had not been the case.

Case II.—Reported by James Seaton in the *Medical Times and Gazette*, in 1859. This was one of ten cases of poisoning by belladonna berries, the patient being a child. Eight minims of tincture of opium were given every half-hour at first, and afterward the dose was increased to twelve minims. Death ensued at the expiration of twenty-nine hours from the time the poison was taken. Altogether seventy-two minims of laudanum were taken—which is about equal to three grains of crude opium—and this quantity was entirely too little to counteract the effect of a lethal dose of belladonna. The post-mortem showed, however, that the heart was flabby and that there was pleural effusion and adhesions.

Case III.—Reported by Samuel W. Gross in *The American Journal of the Medical Sciences* for October, 1869. The patient was a lady, forty-three years of age, and she took four pills containing three grains of atropia, which were sent her through the mistake of a druggist. Among the other symptoms there was complete muscular relaxation, with the exception that there was trismus of the lower jaw. At first an enema and quantities of emetics were given, and then half a grain of morphia was administered hypodermically, after which the respirations became twenty to the minute. The effect being temporary, however, the dose was repeated, when the respirations again became twenty. The faradic current was also employed, and respiration was kept up artificially. Later, a third half-grain of morphia was given, but the respirations now becoming fourteen to the minute, and stertorous in character, it was decided not to give any more opium. Artificial respiration was continued, and the use of the faradic current and flagellation after a time seemed to restore the patient to partial consciousness. Subsequently she appeared to sink into a natural sleep, the respirations then being eighteen. Just as the medical men were about to leave her, however, the toxic symptoms returned. Veratrum ointment was now rubbed vigorously into the skin along the spine, and artificial respiration being resumed, she seemed to improve again. About this time some of the urine was injected into a cat, when it was found that the animal's pupils became dilated. No more morphia was given, and the patient finally expired. At the autopsy it was found that the superficial veins were congested and that the veins of the brain were also very full, while there was general softening of the cerebral tissue. The tissue of the heart was also soft and easily torn ; so that this case can hardly be regarded as a failure for the doctrine of antagonisms. In view of the considerable quantity of atropia taken, moreover, scarcely less than six grains of morphia were needed to counteract its effect. After the first dose of one-half grain, the trismus of the jaw ceased and the respiration became twenty. A little later no inconsiderable portion of the belladonna poison must have been already eliminated, since, as we have seen, the injection of the patient's urine into a cat was sufficient to produce one of the most marked physiological effects of the drug. It is of no little importance in such cases to estimate the quantity of the poison that is being eliminated. The case was a very unfavorable one, however, from the condition of affairs revealed by the autopsy, and there can be little doubt that the heart was in an advanced stage of fatty degeneration.

Case IV.—Reported by Dr. Southam in the *British Medical Journal*, in 1868. The patient was thirty-eight years of age, and took two ounces of laudanum. Nearly eighteen hours had elapsed before he came under treatment, and by that time the pupils were contracted to a pin's point, and the respirations had become reduced to four in the minute. The hypodermic injection of $\frac{1}{36}$ of a grain of atropia was given, with the effect of raising the respirations to nearly the normal number ; but this beneficial effect was very brief in duration. Accordingly, the dose was repeated, until five in all had been taken. At the autopsy there was found to be marked congestion of the lungs.

Commentary.—The poison had already been absorbed when the treatment was undertaken, and there was an obvious deficiency in the employment of the atropia. As the whole of the opium remained in the blood, the whole of the atropia ought to have been given at once instead of in divided doses, so as to make a more profound and prompt impression. In a similar case Milner Fothergill administered one grain of atropia at once, and with entire success. Of course the long duration of the toxic symptoms before the remedy was given constituted an unfavorable element in the case.

Case V.—Reported by Dr. Paget in the *British Medical Journal*. A child three and a half years old swallowed an unknown quantity of laudanum, and in order to counteract its effects, $\frac{1}{100}$ of a grain of sulphate of atropia was given in four hours after the taking of the poison. No appreciable result following this, a second dose of half the quantity was promptly administered, and after this it was noticed that the pupils dilated slowly, while the extremities grew cold and the respiration began to fail. Artificial respiration was then resorted to, and, in addition, coffee was given and ambulation and flagellation employed. There was then a temporary improvement, but death took place in twenty-eight hours.

Commentary.—The important effect of atropia on the pupil and the brain is well shown in this case. Here it is probable that the first injection of the remedy was sufficient, for after the second the coldness of the extremities was noticed. It would have been decidedly better to wait and see what the effect of the first dose was before resorting to a second. It seems altogether likely, therefore, that here the amount of opium taken was not very large, and that the too free use of the antagonistic agent, together with the other active treatment employed, proved too much for the strength of a child of three and a half years.

Cases VI. and VII.—Reported by Dr. Haynes, of Philadelphia. One of the patients took an ounce and a half of laudanum, and the other one ounce of crude opium. In both these cases the doses of atropia were much too small, and hence the source of failure was sufficiently plain.

Cases VIII. to XIII.—These were reported by James Johnson, and occurred in the Chinese hospital at Shanghai. In all there was profound opium-poisoning, and in each but one dose of atropia was administered, the amount given being totally inadequate to counteract the effects of the poison. All of the cases occurred in the practice of Dr. Johnson, whose experience has been exceptionally large in this class of cases. He considers the effects of atropia marvellous, and says that in the profound coma of opium narcosis he knows of no other remedy whatever that can produce a beneficial result.

Case XIV.—Reported by Horatio C. Wood, of Philadelphia. In this case one and a half grains, and afterwards one and a quarter grains of opium, had been given for the relief of cholera morbus. To antagonize the profound narcotic effect produced by it, fourteen hypodermic injections of atropia were administered, the whole amount given aggregating one-quarter of a grain. Here the underlying disease, no doubt, had much to do with the fatal result, and such a case is of small value, owing to the uncertainty which is thus introduced into any estimation of the antagonistic action of the two agents.

Case XV.—Reported by Dr. Beddoe. The patient took a teaspoonful of belladonna liniment, and death ensued in sixteen hours. Three injections of morphia of one grain each were given in all. It was found that decided stupor followed the second dose, and hence the third should have been withheld, for after that the patient breathed stertorously, notwithstanding the fact that the pupils remained widely dilated.

It was noted by the observers present that toward the last the case precisely resembled one of opium-poisoning, with the exception that the pupils were dilated instead of contracted ; and this leads me to say that the condition of the pupils in such cases cannot always be depended upon as an index of the actual effect of the antagonistic agents upon each other and upon the system. But, owing to the lateness of the hour, I shall have to defer until next week the further consideration of this subject.

Children's Summer Sanitarium.—The Treasurer of the Children's Aid Society reports that Mr. D. Willis James has given the society $10,000 for the establishment of a summer sanitarium for sick children.

The same society reports that at the Summer Home at Bath, during the past season, 3,084 sick children were treated.

Original Communications.

NOTES OF FOUR CASES OF PHARYNGEAL TUMOR (MYXO-SARCOMA),

With Remarks.

By GEORGE A. PETERS, M.D.,

ATTENDING SURGEON ST. LUKE'S HOSPITAL, ETC.

(Read before the New York Surgical Society, October 25, 1880.)

Case I.—My friend, Dr. Andrew H. Smith, sent me a patient named Annie Dermody, aged thirty-nine years, United States, single, laundress, who was admitted into St. Luke's Hospital September 27, 1878. Patient states that seven years ago a tumor about the size of an English walnut suddenly appeared inside the mouth, at the back part of the lower jaw, upon the left side, which she took to be a gumboil. The swelling was not accompanied with pain. There was no carious tooth in the jaw, nor was there any redness of the cheek opposite the site of the tumor. She consulted a physician immediately, who said it was an abscess, and treated it as such for three months, puncturing it seven times during that period, twice with an instrument resembling a long darning-needle, and five times with a lancet. There has been no discharge from it except a little blood and pus at the time of the first puncture.

For five years the tumor remained stationary and caused her no annoyance. Two years ago it began to grow, and has slowly increased in size to the present time. One year ago she became quite deaf in the ear on the affected side, accompanied with a roaring sound. This she attributed to a "cold," and it lasted but a few weeks. There is no family history worthy of remark in this connection. General health good, and menstruates regularly.

The only trouble she now experiences from the tumor is an increasing difficulty in deglutition, but not accompanied by pain. Is obliged to depend chiefly upon fluids for nourishment. Respiration is not interfered with. Voice nasal.

On admission, the tumor presented the following appearances, viz.: externally the left cheek is somewhat swollen, especially over the body of the lower jaw. The swelling extends slightly before the angle of the jaw, and downward into the neck for a distance of about two inches below the lower edge of jawbone. Forward, externally, the tumor extends as far as a point opposite the second bicuspid tooth. This swelling is quite hard, and the skin is freely movable over it. On opening her mouth, which she can do with ease, the tumor is seen to occupy about half the buccal cavity, pressing the tongue over against the teeth of the right side, and hiding the left tonsil from view. Forward, on the left, the tumor extends as far as the first molar tooth of the lower jaw, but lies back of all the teeth of the upper jaw, springing from the alveolar ridge behind them. From these points it extends across the roof of the mouth, slightly beyond the median line. The finger can be readily passed upward around its posterior border, but the longest finger cannot reach its lower border in the pharynx. The tumor is covered by healthy mucous membrane, has a firm consistence and semi-elastic feel. No point of fluctuation. Aspiration yields no fluid.

Examination of the urine gives negative results.

October 10th.—Removed the tumor, assisted by Drs. McBurney, Sabine, and others. After the patient had been brought under the influence of ether in the usual way, an opening was made through the crico-thyroid space, and my modification of Trendelenburg's canula was introduced, through which the etherization was continued throughout the operation. The left cheek was then laid open through its entire thickness, from the angle of the mouth outward. The jaws were then forced apart with a mouth-gag, exposing the tumor well to view.

An incision was made through the mucous membrane, about three inches long, over the most prominent part of the tumor. Enucleation was then done, chiefly with the fingers. This was rendered difficult by the size and depth of the mass. After about one-third of the tumor had been enucleated the investing sac burst, and the contents, resembling soft cartilage, exuded freely. Finally, the entire sac was removed, with its remaining contents, the finger at one time touching the cricoid cartilage. Hemorrhage moderate, no vessels requiring the ligature. The edges of the wound in the mucous membrane were brought together with two fine carbolized silk sutures, and a rubber drainage-tube was introduced, the end projecting from the angle of the mouth. The wound in the cheek was secured with hare-lip pins and carbolized silk sutures. Trendelenburg's canula was then withdrawn, and the wound closed with carbolized silk sutures. Patient rallied well and had no vomiting. Ordered strictly milk diet, carefully administered.

By the 14th of October all the sutures from mouth, face, and neck had been removed.

By October 24th the wounds, except that through the mucous membrane over the tumor, had healed. Patient had a teazing, irritative cough, which finally ceased, and she was discharged cured on the 19th of November, 1878, at which time, on looking into the mouth, hardly a trace of operative procedure could be detected. Dr. Satterthwaite reports as follows:

"*Pathological report.*—The specimen consists of a number of soft, pulpy, almost gelatinous masses, surrounded by gelatinous fluid. On microscopical examination it was found to be composed of connective-tissue fibres studded with connective-tissue corpuscles of various forms, some having tail-like processes (at two or three points). The connective tissue and corpuscles, at many points, were in a state of mucoid degeneration. This was decided to be a myxo-sarcoma—by which is meant one that has round, oval, or stellate corpuscles or a mixing of the ordinary elements of sarcoma."

Up to this time, October, 1880, there has been no return of the disease.

Case II.—October 2, 1880. David Lauderbach, aged forty years, United States. Admitted to St. Luke's Hospital with following history: Has never had syphilis; urine normal. Up to three years ago he had frequent attacks of quinzy sore throat, since which time he has been free from them.

About five months ago he noticed that his throat felt sore on rising in the morning, and he swallowed with difficulty. These symptoms increased in severity. For the past three months he has not been able to swallow solid food, and has lived principally upon milk and beer. During this time he has lost thirty pounds in weight.

Externally a slight fulness is observed below the angle of the jaw upon the right side. On opening the mouth a tumor is discovered in the posterior fauces extending down into the pharynx. Tumor is oval in shape, situated beneath the pharyngeal mucous membrane, and attached by a broad base posteriorly and to the right side, hiding the tonsil from view. The mass extends inward and pushes the uvula to the left side. The entire boundary of the tumor cannot be reached with the finger, especially at its lower part, which extends nearly to the cricoid cartilage, but the finger can be readily passed above and behind it.

The tumor gives an elastic feel, and is covered by healthy mucous membrane. Patient is somewhat anæmic and says he is losing strength rapidly. Respiration is somewhat embarrassed during sleep. Voice nasal.

October 11th.—Operated this day, assisted by Drs. McBurney, Sabine, and Bull. Several other surgeons were present.

Patient etherized in the usual way, when laryngotomy was performed, and the improved Trendelenburg's canula was introduced, through which he breathed and took the ether in the subsequent steps of the operation. The jaws were forced apart with an instrument, and a ligature passed through the tip of the tongue by means of which that organ was drawn well over to the left side of the mouth. A piece of sponge, with a long string attached, was then passed into the throat, shutting off entirely the trachea and œsophagus.

An incision was now made through the mucous membrane covering that part of the tumor in view. The first attempt at enucleation with the finger broke through the thin investing sac, and the contents, resembling soft cartilage, oozed out. The mass was rapidly broken down with the fingers, after which the sac was seized between the jaws of a fenestrated pile-forceps and entirely removed. Hemorrhage was moderate; no vessel requiring the ligature.

Removed the tracheal canula, and brought edges of the wound together with fine carbolized silk ligatures, passed merely through the thickness of the skin. No sutures were used in the wound of mucous membrane in the mouth, nor was any attempt made to drain it. Patient recovered well from the effects of the ether and had no vomiting.

October 12th. — Patient passed a comfortable night. Swallows with considerable difficulty, but is able to take a fair amount of milk. Has but little pain. Ordered a mouth-wash of sol. chlorate of potash and myrrh. On the second day after the operation patient's temperature rose to 102°, but as there was no swelling or tenderness in the throat I was forced to look in another direction for the cause, and found it in a rectum impacted with fæces, on removing which his temperature fell and he improved daily.

October 25th.—Wound in fauces is healed, and he swallows with ease. There is no swelling to be discovered. Wound over the larynx externally is closing by second intention.

November 6th.—The wound in the larynx is entirely healed and the irritative cough has ceased. All the wounds are now healed.

Pathological report.—Dr. Satterthwaite reports: "It is either a fibro- or myxo-sarcoma; probably there is an admixture of both mucous and fibrous elements, but which was in excess I cannot say now."

Case III.—Professor Henry B. Sands has kindly furnished me with his notes of a case operated upon by him, which read as follows, viz.:

October 15, 1878.—Henry Sands, aged twenty-eight years, Norwich, N. Y., came with Dr. L. I. Brooks to consult me with regard to a post-pharyngeal tumor, which was first noticed last December, but which probably existed at least eighteen months ago, as at that time his voice was observed to have a nasal tone. Dr. Brooks saw the case first on May last, and thinks that since that time the tumor has not grown much larger. No hereditary antecedents. Patient seems rather anæmic, and says he has lost ten pounds since last June. Appetite fair. Complains of slight debility.

The tumor is oblong, situated beneath the pharyngeal mucous membrane and attached posteriorly and on the left side, where it hides the tonsil from view. The palatal mucous membrane is expanded over it and the uvula lies on its right surface in contact with the fauces. The tumor fills the pharynx below the level of the palate, and can be felt in the submaxillary and parotid regions, where it is slightly prominent. It is somewhat movable laterally, but seems closely attached on the left side. The mucous membrane over it is healthy. Left carotid apparently not enlarged. No complications. Urine normal.

Patient says he can swallow easily, but he takes hardly any solid food. Respiration is sometimes embarrassed during sleep. Voice nasal. The tumor is moderately firm and elastic. Dr. Brooks has determined its solid character by means of the aspirator.

October 22d.—Dr. Sands removed the tumor assisted by Drs. Markoe and Curtis. Dr. Geo. A. Peters was also present. Ether, laryngotomy. Trendelenburg's canula, the action of which was entirely satisfactory, the only inconvenience noticed being a momentary irritation of the tracheal mucous membrane when the rubber bag was inflated. Made one vertical incision, about three inches long, over the most prominent part of the tumor, and then effected enucleation mainly with the fingers, using the scissors to divide a few bands of connective tissue. The tumor was not unlike soft cartilage, and seemed to be a myxo-sarcoma. It came to pieces in the attempt to remove it, and appeared to be contained in a well-defined capsule of areolar tissue, which was also taken away, leaving the surrounding parts, as far as could be ascertained, entirely healthy. The bleeding was very moderate, and no vessel required the ligature. United the upper half of the wound with three silk sutures. Removed the tracheal tube and closed the wound with silver sutures. The operation lasted forty-five minutes.

October 25th.—Patient has done well since the operation. Until last evening the bladder had to be emptied by a catheter.

Yesterday he was hoarse and complained of difficulty in swallowing, but was free from dyspnœa. Has been fed on beef-tea and milk. Removed silver sutures to-day, the wound in the neck having entirely healed by the first intention.

October 26th.—Patient feels quite well and wants to sit up. 9 P.M.—Has suffered from headache, and passed an uncomfortable day. Feels better now. Swallows without difficulty. Temperature, 101°.

October 27th.—Doing well; removed sutures from palate, which was united.

October 28th, 12 M.—Had an uncomfortable night Being kept awake by a cough and expectoration, the substance expectorated containing considerable pus Temperature, 100⅗°; pulse, 104. Left side of neck near angle of the jaw, slightly swollen and tender. Swallows without difficulty, but still takes only soups, etc., except raw oysters, which are not masti cated. Inspection of the pharynx does not explain the cough; neither does auscultation; the breathing being normal. 5 P.M.—More comfortable. Took one-eighth grain of morphine and slept several hours during the day. Felt chilly an hour since, but had no rigor. Coughs less. Pulse, 104; temperature, 101⅘°.

October 29th.—Pulse, 124; temperature, 101⅖°. Considerable swelling in pharynx and behind angle of jaw. Deglutition difficult. Wound cavity discharges freely; washed it out with permanganate of potash, introducing with a syringe. No dyspnœa, but occasionally troublesome cough.

October 31st.—Much better. Temperature, 98⅖°; pulse 96. Swelling and suppuration greatly diminished.

November 1st.—Convalescent.

November 10th.—Quite well. Is able to walk out.

November 14th.—Patient left for home.

Dr. Delafield writes as follows: The tumor of the pharynx removed by you is composed of, 1st, connective tissue; 2d, mucous tissue; 3d, adipose tissue; 4th sarcomatous tissue; 5th, irregular glandular follicles, lined with polygonal epithelium, and containing masses of hyaline matter.

It is not a cyst, but a solid tumor which has softened at the centre. It seems to belong to that class of composite tumors which occur most frequently in the parotid and submaxillary region. It might be called an adenoid myxo-sarcoma.

The prognosis is that of local recurrence, but without metastatic growth.

October 16, 1880.—Patient called to report himself in excellent health. No return of tumor. Phonation and deglutition perfect.

Two years have elapsed, and there has been no return of the tumor.

CASE IV.—Dr. Morris J. Asch has kindly furnished me with the following brief notes of a case of pharyngeal tumor upon which he operated in 1877. Mrs. H——, aged fifty years, came to me in April, 1875, complaining of sore throat. Examination showed the right tonsil to be hypertrophied, with some swelling of the velum above it. Local applications having failed to relieve, a portion of the tonsil was excised. Nearly two years afterward, in December, 1876, the patient again presented herself. She was suffering from dyspnœa and dysphagia, and articulation was seriously impaired. Inspection revealed a hard and elastic tumor filling up nearly the entire pharyngeal space. It involved the whole of the soft palate on the right side, extending downward between the pillars to the free border of the epiglottis, and across, pushing the uvula before it to the pillars of the opposite side. Backward it extended to the wall of the pharynx, against which it was pressed so firmly that its extent upward could not be determined. The anterior pillar of the right side was stretched tightly over the face of the tumor, and the tonsil of the same side was not visible. As the functional trouble was very severe I determined to remove the tumor at once, and after showing the patient at a meeting of the New York Laryngological Society, I performed the operation, on January 4, 1877, in the presence of Drs. Erskine Mason, McBurney, Beverley Robinson, Dawson, and others. The patient being put under he influence of ether, an incision was made in the face of the tumor from the hard palate, downward; with some difficulty the tumor was enucleated; the sac drawn out and severed from its attachments by he galvano-cautery. Some trouble was experienced during the operation by blood flowing into the larynx, but no serious inconvenience resulted. The tumor was submitted to several microscopists for examination, and was pronounced by Drs. Heitzman and Mann to be myxo-sarcoma. The patient made a good recovery. The functional troubles were entirely relieved, and up to the time of the present writing (October 21, 1880)—a period of four years—I have not heard that the growth has reappeared.

Remarks.—I am here enabled to present to the society an interesting group of four cases of tumor of the pharynx, apparently identical in character, and certainly rarely encountered. During an experience of thirty years, and for the greater part of that time connected with large hospitals, Case No. 1 (that of Dermody) was the first tumor of the kind which had been brought to my personal notice. Her case was one of such interest that a large consultation was held, at which many surgeons other than the immediate staff of St. Luke's were present. No one of them had seen a similar case, and there was great diversity of opinion as to its nature and the best method of operation.

I have consulted many of the systematic works on surgery easily accessible and find but little light thrown upon the subject of tumors of the pharynx. Some writers ignore the subject entirely, while others merely allude to polypoid and cancerous growths in this situation, and state that these are of rare occurrence. Holmes, in his "System of Surgery," gives more space to the subject than most writers, but he devotes only two scant pages to its consideration. He states that "tumors attached to the pharynx are not very commonly observed. When they occur, they are generally apt to be somewhat pendulous, and are often attached to a portion of the walls by a narrow neck. They have been found to consist of fat and fibrous or fibro-cellular tissue." He mentions the record of a fatty tumor of the pharynx, by Mr. Holt, in the "Transactions of the Pathological Society": "This specimen was removed from the body of a man eighty years of age. Twelve years previously his attention had been first drawn to his throat, from an occasional sensation of choking. About four years previous to his death, during an attack of vomiting, a large mass was protruded into the mouth, and, to prevent immediate suffocation, he was compelled to return it as quickly as possible. He was at all times better able to swallow fluids than solids. He died suddenly, while in the act of smoking. The tumor was found to be a large, pendulous, fatty mass, filling the pharynx and extending downward to the œsophagus for nine inches. It was attached by fibrous tissue, covered by mucous membrane to the left side of the epiglottis, and also to the upper part and side of the pharynx. The tumor had by its weight so dragged upon the epiglottis that the perfect closure of the laryngeal aperture was not practicable. The mass, except at its attachments, was hanging loose in the pharynx and œsophagus. It consisted of adipose tissue." Holmes also mentions two specimens of tumors of the pharynx in the College of Surgeons, successfully removed during life: "One is a large, soft lobulated mass, apparently fatty or gelatinous, like a nasal polypus; it was attached by a narrow pedicle behind the tonsil. A second is apparently a firm fibrous mass, and was attached by a narrow pedicle to the wall of the pharynx." He also states "that tumors, either of a fibrous or fatty structure, which are not pendulous, have been seen to grow and insinuate themselves under the mucous membrane; and as they increased in size so they interfered with the aperture of the glottis, and interrupted the passage of food to the stomach."

At a meeting of the American Larnygological Society (*St. Louis Med. and Surg. Journal*, September, 1879), Dr. F. I. Knight, of Boston, reported a case of retro-pharyngeal sarcoma. His case induced Dr. Knight to look up the records of similar pharyngeal growths and to make brief abstracts of cases found. The result is a record of cases described by Arnott, Busch, Röser, Wagner, Larondelle, Rosenbach, Venturini, Billroth, Syme, J. Carreno, S. H. Chapman, and Cohen, of Philadelphia. In the larger number of the cases described the tumor was attached to the walls of the pharynx by a pedicle. I would refer all who are interested in this subject, and who have not ready access to the *St. Louis Journal*, to the monthly abstract of *Medical Science*, for Nov. 1879, vol. vi., No. 11, p. 504, where they will find a *résumé* of the paper.

That so little is said on this subject by writers on surgery establishes the rarity of the occurrence of tumors in this situation.

Most writers recommend the early removal of polypoid and pendulous growths in the pharynx, but insist strenuously, that the only hope of benefit must be from treatment restricted to the pendulous form of tumor, stating that the attempt to remove a tumor attached throughout to the walls of the pharynx would be a highly dangerous proceeding, and most probably unsuccessful in its results if not fatal during its progress.

One object of this paper is to contend, that in the past surgeons have overestimated the dangers attending this operation, and to suggest a plan of operation, which will reduce the danger to a minimum.

In my first case, as I have stated, no one present at the consultation was able to give the result of any experience as to the best method of procedure, and I was left to work it out myself. On reflection, I determined to be prepared, so far as possible, to meet any danger or complication which might arise. The tumor was a very large one, filling up most of the buccal cavity, and giving very scant room to work through the natural opening of the lips. I therefore determined to split the cheek, thus giving me more room. Fearing that this opening might not give me sufficient room, or that the tumor might not be enucleable and require a tedious dissection for its complete removal, I had a dentist make a gutta-percha splint for the jaw and was thus prepared to make a section of the lower jaw, if necessary. Recognizing that the chief danger to the patient would be from the entrance of blood during the operation, into the trachea through the epiglottis, I determined upon laryngotomy as a preliminary step, believing that experience had proved laryngotomy to be a simple operation and safe in its results, provided the parts are in a healthy condition, and that no danger or irritation need be apprehended from the introduction of the tube.

All the steps of the operation, previously determined upon, were pursued with the exception of section of the jaw-bone, which was not found to be necessary. Trendelenburg's canula did not give me entire satisfaction, as the inflation of the rubber bag caused temporary irritation of the larynx, whenever it was distended, and it is also very difficult to keep up perfect and continuous inflation. My improvement of Trendelenburg's canula, alluded to above, consists in considerably shortening its length; in so arranging the rubber collar, that when it is inflated it will not occlude the lower opening (as I have known it to do in the original instrument), and the method of supplying air to the collar through a smaller silver tube within the larger one. The result of the operation in the case of Annie Dermody was in every way satisfactory, and I felt much better prepared, by the experience thus gained, to attack my second case, that of Lauderbach.

In this case the tumor was somewhat smaller, so that I was enabled to get sufficient room to remove it without splitting the cheek, thus avoiding the scar resulting; although the natural opening through the lips was so small, that I was more than once tempted, during the procedure, to make the incision. In this case (No. 2) I relied more upon the sponge, which was made to fill up the throat, for preventing the entrance of blood into the air-passages, than upon Trendelenburg's apparatus. Indeed, I consider that the ordinary tracheal canula, together with the sponge in the throat, will answer every purpose.

It will be seen by Dr. Sand's report of his case, that he also considered it advisable to commence his operation by doing laryngotomy; and the value which Dr. Asch places upon that procedure may be best learned by his own testimony.

Dr. Asch, in a note received on the 24th of October, 1880, says that the only real difficulty met with in his operation resulted from the want of experience as to the value of tracheotomy in similar cases. The bleeding was very profuse at times and would get into the larynx, rendering it necessary to delay the operation, in order to clear the throat of blood and to re-establish suspended respiration. This occurred several times, extending the time of the operation to one hour and forty-five minutes.

Recapitulation.—First. These four tumors all presented the same pathological appearance, belonging to the class known as mixo-sarcoma. They were invested by a sac-wall of considerable firmness, and were enucleable.

Second. Tumors of a large size, situated in the pharynx and having very broad origin and attachments can be removed with safety, and will be found in many cases to be enucleable. Should the tumor be of considerable size and distinctly cancerous in its nature, I should recommend non-interference.

Third. I should in all cases perform laryngotomy, as a preliminary step in the attempt to remove the growth, believing it to be a safe procedure.

Fourth. I should provide against the flow of blood into the trachea by the use of Trendelenburg's canula, and as an additional precaution crowd a piece of sponge with a long string attached into the pharynx, so as to shut off the laryngeal opening and œsophagus.

Fifth. A tumor of considerable size can be removed through the natural opening of the lips, although it greatly facilitates the operation to split the cheek, and in some cases it may be necessary to saw through the jaw-bone. The only objection to incising the cheek being the scar which remains: this is to be avoided, when possible, especially if the patient be a female.

* * *

Transmissibility of Bovine Tuberculosis.—Further evidence of the transmissibility of tuberculosis from cows to other animals through the milk has been obtained by M. Peuch. He fed two pigs, and some rabbits were fed upon the milk of a tuberculous cow for from one to two months. The animals, on being killed, were in each cases found to have tubercles. It should be added, however, that the tubercles were very few in number, and had caused no marked symptoms.

ELECTRICITY AS A PARALYZING AGENT IN THE TREATMENT OF EXOPHTHALMIC GOITRE.

BY THOMAS W. POOLE, M.D.,

LINDSAY (ONT.), CANADA.

Dr. A. D. Rockwell, of New York, has offered to the readers of The Medical Record, on two occasions (October 4, 1879, and September 11, 1880), interesting and useful reports of cases of exophthalmic goitre treated by electricity. For some time past I have held and advocated (Medical Record, November 1, 1879) that electricity is essentially a paralyzing agent; and I propose to show here, as briefly as possible, that the beneficial results thus recorded in exophthalmic goitre are due to the paralyzing action of electricity, and not to any supposed stimulant, tonic, or other quality with which this agent is popularly accredited.

While seeking to avoid the prolixity of an enumeration of the symptoms of this disease, which are well known or easily accessible, it is necessary to glance at the general physiology and pathology of the implicated parts. The thyroid gland is in part composed of "a dense capillary plexus." It is fed by four large arteries passing directly to it from great arterial trunks. These thyroid arteries are "remarkable for their large size and frequent anastomoses." They are occasionally supplemented by an additional artery derived from the arteria innominata. If the gland be not an erectile tissue, as has been suggested, it is at least extremely vascular. Dr. Sœlberg Wells writes: "Its veins are generally much dilated, even, perhaps, to such a degree that the disease might be termed 'bronchocele aneurysmatica;' and often a distinct diastolic murmur can be heard in them" ("Dis. of the Eye," p. 710). Again, "among the first symptoms are great palpitation and acceleration of the action of the heart," leading, after a time, to "dilatation and hypertrophy, especially of the left ventricle" (Ib.). To this, join increased pulsation in the carotids, inflamed eyelids, injected conjunctivæ, the presence of "hyperæmic swelling of the adipose cellular tissue of the orbit," and as "Dr. Wright found, besides strong dilatation of the veins, a small quantity of half coagulated blood extravasated over the eyeball" (Ib., p. 711), and there can be no room to doubt that the pathological condition is one of extreme vascular dilatation and engorgement, in which an excess of pabulum leads to hyperplasia of tissue.

Now, the calibre of the dilated arteries thus conveying an excess of blood is under the nervous control of the middle and inferior cervical ganglia of the sympathetic; but chiefly of the former, which was called the thyroid ganglion by Haller. These ganglia are in direct communication with the spinal nerves, from which their motor power is largely reinforced. The position of the electrodes in Dr. Rockwell's treatment, it will be seen, is eminently calculated to bring these ganglia and their nervous connections within the circuit of electrical influence. Indeed, this is the very position prescribed by electricians for "galvanization of the sympathetic." There can be no doubt, therefore, that it is through these sympathetic ganglia and their vascular or vasomotor nerves that the diseased condition is influenced and its improvement effected.

From this it is evident that the starting-point of the disease is to be sought in some perversion of function on the part of the sympathetic and its vaso-motor nerves, which permits or induces undue vascular dilatation in vessels specially under the control of these nerves. What is this pathological condition of the sympathetic ganglia and nerves? All observers are not agreed. The weight of authority, however, largely preponderates in favor of the conclusion of Sœlberg Wells, that it is "far more probable that the affection is due to an irritation or neurosis of the sympathetic." Thus, "Wright, Moore, Trousseau, etc., found the cervical ganglia of the sympathetic enlarged, hard, and firm. . . . The trunk of the sympathetic, as well as the branches going to the inferior thyroid and vertebral arteries, were found to be enlarged." It is fair, therefore, to conclude that there is here an undue excitation of the sympathetic just as there is also said to be "much nervous excitement" generally.

Here, then, we have vaso-motor (sympathetic) excitation and vascular dilatation with hyperæmia; a cause and effect, which (in spite of the theory of the day) are found in constant association, just as vasomotor paralysis and arterial contraction also go together; for *at no time is arterial contraction so general and complete as in death, when nerve-force is extinct.* Here the property of contractility in muscle survives nerve-force, contracting these tubes to the emptying of their contained blood into the veins, which, though more capacious than the arteries, undergo material distention.

In the cases under consideration the electric current, by *a moderate paralysis of the excited vaso-motor nerves*, brings about a reduction in the calibre of the arterioles of the parts affected; thus gradually putting an end to the vascular engorgement on which the exophthalmic goitre depends.

Arterial contraction is never produced by a stimulant. In whatever degree it occurs, it is a tendency toward the contraction present in death; and the agents which produce it are inimical to life in a greater or lesser degree, according to their power. Electricity produces this effect on the arterioles, through their controlling vaso-motor nerves, by paralyzing them; because only by withdrawing nervous force could it do in part what the extinction of nerve-force renders complete. In other words, a progressive diminution of nerve-force is necessary to arrive at a goal where nerve-force is extinct, that is, where arterial contraction is most complete. Free play being thus afforded to the property of contractility in the arterial muscle, it, like all other muscles, passes into a state of contraction in proportion to the absence of nervous influence (Dr. C. B. Radcliffe, F.R.S., "Lectures on Epilepsy," etc., p. 100).

Hence, for curative purposes, only a moderately paralyzing wave of electricity is permissible; otherwise undue arterial contraction will induce anæmia of the brain, with dizziness, loss of consciousness, and other alarming symptoms, well known to bold electricians. No one will venture to call in question the fact that electricity produces the effect on the vascular system here stated, since it has been definitely proved by direct inspection of the vessels of the dura mater and pia mater during external applications of the electrodes to the neck and scalp. Furthermore, the greatest degree of contraction occurred at the moments of interruption of the galvanic current, a circumstance which accords with Dr. Rockwell's greater success with the faradic or interrupted current (*Gazette hebdom.*, Oct. 3d).

Nor is the fact that arterial contraction is thus produced by electricity at all inconsistent with the other fact, that electricity, when superficially employed, may produce local hyperæmia. It does so by the contractions it occasions in muscles, which exercise them, and thus blood and pabulum are attracted to their substance, and, if suffering from disuse, their nutrition is improved. But even here the muscle derives advantage at the expense of the nerve, the function of which is temporarily arrested in order that the muscle may contract. Hence it is, that the muscles of a limb, whose motor nerves are already partially paralyzed by disease, contract to a weaker current of electricity than will suffice for the muscles of a limb whose nerves are acting normally (Dr. J. Russell Reynolds, "Lec. on Clin. Uses of Elec."). The weaker current suffices to extinguish the power of the feebly acting nerves, but fails to annul the vigorous action of the healthy ones. If electricity were a stimulus to nervous action, it is obvious that results the very opposite ought to follow.

I must pass over further discussion of this part of the subject, in order to notice briefly a statement commonly made on high authority, and very generally accepted. It is that a moderate current of electricity acts as a stimulant, while a very powerful current paralyzes. (Dr. A. H. Bennet, *Brit. Med. Journal*, Jan., 1880, p. 46; last "Braithwaite," p. 71.) It is impossible that this proposition can be true. Electricity is one of the forces of nature, and the mode of action of the natural forces is necessarily invariably uniform and consistent. From the spark of the battery to the flash of lightning there is an immense progression in power, but the addition of any number of sparks to that of the battery can in no way change its character or modify its mode of action, which is ever the same, and tends toward the same goal. Just as the flash of lightning kills, the battery spark tends to kill, in proportion to its power, and only fails to kill because of its feebleness and the counter-action of opposing forces. We take advantage of its weakness (as we do of fire, water, heat, etc.) to render it beneficial to us; and if the *effect* produced is different from that of the very powerful current, or the scathing lightning, it is not that the thing itself has changed its nature or modified its mode of action. If the greater discharge of electricity is a paralyzer, the battery spark is a paralyzer, too, in proportion to its power; the difference being not in quality but in degree. To assert otherwise is to controvert the plain teaching of natural science.

The same law of uniformity applies to the action of drugs, which are the embodiment of natural forces; and any really scientific exposition of their mode of action must repudiate the ideas now current, that a given drug reverses its mode of action in varying doses, or that it stimulates one nerve or one portion of a nerve while paralyzing another. (Dr. Ringer, belladonna, etc.).

In conclusion I may add, that a practical experience of some years in the use of electricity confirms the views expressed above as to the character of its influence on the nervous system. I do not deny its utility—like other paralyzers—in appropriate cases. But it bears a wrong label. The erroneous estimate which assigns it a place as a stimulant, tonic, or vitalizer, has been a fruitful source of much charlatanry, and has led also to numerous erroneous inferences both in physiology and therapeutics. Because it arrested the frog's heart, which it could hardly do as a stimulant, other nerves, antagonistic to the cardiac motor nerves, must be found to suit its assumed action. Hence the purely imaginary "inhibitory" system of nerves, with equally hypothetical inhibitory "centres," arraying the entire field of innervation in two hostile camps, the function of each being to countermand or interdict the action of the other, involving a frightful waste of force in the organism.

We smile now at the Archæus of Paracelsus, that "imaginary demon" supposed to preside over certain bodily functions. Future generations will smile at many of the notions of to-day, and recognize the simple fact that electricity stops the heart by paralyzing its motor ganglia.

NOTE.—Since the foregoing has passed out of my hands, I find in the simple facts of the authentic experiments, ample and conclusive proof of the paralyzing character of the electric current, in all its phases —intra-polar, extra-polar, direct, and inverse. I hope soon to submit this proof to the Editor of the RECORD.

FOREIGN BODY IN THE URETHRA.

By CHAS. M. SELTZER, M.D.,

RESIDENT PHYSICIAN TO THE EPISCOPAL HOSPITAL, PHILADELPHIA.

THE following curious case is another instance of that form of human depravity of which we rarely hear, and then only when the culprit is brought to grief:

J. Y——, aged forty-four years, was admitted to the hospital August 26th, complaining of pain in his perineum, difficulty in urination, and inability to walk without great pain. His history was entirely negative, though a purulent discharge was seen issuing from his urethra. Upon making an examination, I felt a projecting, hard body in the median line of the perineum, half-way between the anus and scrotum; this, upon being sharply questioned, he confessed to be what he called a long pencil, that he had attempted to introduce into his urethra while "foolish from drink" the Saturday night previous (August 21st), and after it was part way in it slipped from his fingers, and passed beyond his reach. Upon introducing the finger into his rectum, the object could be felt projecting into the bladder, but the end of it could not be reached. The bladder was not overdistended, because the urine dribbled out alongside of the foreign body. The case was transferred to the ward of Dr. Chas. B. Nancrede, Surgeon in charge, and the next day he attempted to withdraw the body by means of various urethral forceps and instruments; but fearing the use of too much force, lest the bladder or urethra be injured, it was deemed advisable to perform median perineal section.

An incision about one and a half inches long was made into the urethra, in the perineal median line, and the end of a wooden handle of a common penny penholder was exposed. This was seized with the forceps, and the entire handle, five inches long, was withdrawn, the removal of which was followed by the escape of a moderate amount of pus and urine. The bladder was washed out, and a flexible catheter introduced through the urethra. Two days later the catheter was removed, and the patient had no difficulty in passing his urine, very little of which came through the wound. A wash composed of ac. salicylic, gr. xx., aquæ, Oj., was applied to the wound, and the following infusion given for his cystitis:

℞. Foliæ buchu,
Foliæ uvæ ursi,
Sem. lini. ....āā ℥ j.
Sodii bicarbonatis................ ℥ ss.
Aquæ bullien..................... Oij.
M. S.—A wineglassful t. i. d.

His temperature fluctuated slightly between 98.5° and 100°, until the afternoon of the tenth day, when he had a severe chill, followed by fever, and a temperature of 103.4°. Two days later he had another chill, and rise of temperature to 101.4°. No assignable cause could be found for these chills. The wound was entirely healed at the end of the second week, when the patient was placed on tonic treatment, and at the end of the third week was discharged cured.

One of the most noteworthy features of this case is the fact that for six days this man walked around, and sometimes actually worked, with this piece of wood, five inches long, lodged in his urethra and bladder.

Progress of Medical Science.

Acquired Universal Leucoderma.—Dr. George P. Hall, of Belleview, Texas, records a case of leucoderma in the *Louisville Medical News*, September 25, 1880. The affection was at first ascribed to a partial sunstroke, but an examination of the symptoms and course of the disease render it more probable that the primary illness was a remittent fever, and the skin-affection a true malarial leucoderma. The patient, a dark mulatto, became overheated while at work, and lay prostrate for several hours; on recovering from his illness two weeks later he noticed a circular spot of discolored skin, the size of a silver dollar, just beneath the pomum Adami. Other spots of white skin shortly appeared in different situations, till his whole body became pied. This discoloration proceeded slowly for five years, then became quite rapid, and finally the leucoderma became almost universal. There was no evidence of hereditary or specific taint, the general health was excellent, and the functions of the skin were in no wise altered. The patient had been under treatment, but without avail.

Successful Removal of a Cervical Tumor Inclosing a Portion of the Pneumogastric Nerve.—Prof. Lücke, of Strasburg, reports the following case: Mrs. K., æt. 28, in 1878 consulted him in regard to a tumor in the right submaxillary region. She was a well-made woman of healthy complexion, but with a rather poorly developed thorax. Her elder sister had died of hydræmia following a malignant lymphoma of the neck. For this reason the professor supposed that the present tumor, which was oval in shape, movable, and of firm consistency, had the same character. Accordingly it was removed by a simple operation, and the wound healed by primary intention. Upon examination by Prof. von Recklinghausen, the tumor was found to belong to the hyaline variety of epithelioma, and it was thought that it had taken its origin from an ulcerated lobule of the submaxillary gland. The parotid gland was not involved.

In February, 1880, the patient again presented herself with recurrent tumors—one in the cicatrix; a second, larger one, beneath the right sterno-mastoid muscle. Functional disturbances were apparently absent; the patient's general health was good. The cicatricial tumor was readily removed, although there was considerable venous hemorrhage. The larger tumor was then exposed by a longitudinal incision along the border of the muscle; the latter was now seen to be so closely united with the tumor that it had to be cut above and below. The carotid artery was easily separated from the tumor, but the pneumogastric nerve and jugular vein appeared to be entirely surrounded by it. The vein was ligatured just above the clavicle, and again above the upper end of the tumor, and the latter was then exsected together with the inclosed portion of the pneumogastric nerve. Upon measurement this was found to be twelve centimetres long. During section of the nerve disturbances of pulse or respiration were not noticeable. The wounds healed kindly; on the tenth day union was complete, suppuration had not occurred, neither had respiratory disturbances been observed. The pneumogastric nerve was found to be four times its natural thickness, and was interwoven with portions of the tumor. In July the patient was seen again. Her respiration was then easily "excitable," otherwise normal. The right arm was weaker than the left, and the shoulder was not easily lifted. Flattening of right side of neck, and superficial carotid pulsation. Attacks of coughing were provoked by pressure upon the cicatrix. The right half of the face, especially about the cheek, was hypertrophied, which, according to Lücke, resulted from the ligature of the jugular vein.—*Centralbl. f. Chir.*, September 4, 1880.

A New Method of Applying Pressure in Traumatic Aneurism.—Dr. B. R. Palmer, of Sauk Centre, Minn., reports a case of traumatic aneurism of the femoral, resulting from a knife-wound, in which he made an ingenious use of the plaster-of-Paris bandage to facilitate the application of pressure to the artery. He took a band of coarse, thick Mackinaw flannel about six inches wide and long enough to envelop the thigh and lap over about two inches, soaked it in a mixture of the plaster, and applied it to the thigh over the tumor. An aperture was cut in this band, directly opposite that part of the femoral artery just below the profunda, where the pressure was desired. As soon as the plaster had set, about twenty minutes, a piece of cork, properly shaped and covered with chamois-skin, was pressed down upon the artery through this aperture, about an inch of the cork being allowed to project outside the band. A roller-bandage of stout elastic webbing was then applied around the thigh, outside the plaster band, and over the projecting portion of the cork compress, the tension being increased at every turn, until pulsation in the popliteal space could be no longer felt. The apparatus was allowed to remain in situ for about twenty-four hours, with very little inconvenience to the patient. On loosening it there was no return of pulsation, and coagulation of the contents of the tumor seemed to have taken place. In a few weeks the tumor had become absorbed and gave the patient no trouble. Dr. Palmer has also employed this apparatus with great success in the treatment of secondary hemorrhage from gunshot wounds and after amputations, particularly those from frost-bites, where secondary hemorrhage so frequently occurs, and where long-continued pressure is necessary.—*Chicago Medical Review*, September 5th.

Hemorrhage from the Gums Resulting in Death.—A case of hemorrhagic diathesis in a strumous patient, which ended fatally from profuse hemorrhage from the gums, is recorded in the *London Lancet*, Sept. 4th, by Dr. Thorowgood. The bleeding from the gums first showed itself a few days before admission to the West London Hospital. The patient had previously been subject to profuse hæmoptysis, and at times had found "large blue lumps" on the chest, over the sternum, coming without any cause. The swellings lasted a few days, and then disappeared. He had never had any hæmatemesis or melæna, nor any effusion into the joints. He volunteered the statement that four of his relatives had died of the same thing, but did not know what relationship they bore to him. After entering the hospital, the bleeding from the gums was checked for a few hours by astringents, but it then returned as bad as ever. The blood came with a pulse-like motion from the gums of the last two upper molars on the right side; it was watery-looking and seemed to be arterial. The teeth were all sound, white, and painless. On the second day after admission he began to vomit black discolored blood at frequent intervals, and he died of exhaustion on the following day.

A Case of Simple Stricture of the Common Bile-Duct, causing Jaundice and Ascites.—Prof. George Johnson reports a case of simple stricture of the common bile-duct, causing jaundice and ascites, in which the true nature of the pathological changes was not suspected until the autopsy. The main phenomena were: deep jaundice, followed by great ascites; the disappearance of both the jaundice and the ascites after three tappings; the reappearance of the same after an interval of five months. There was no indication of syphilis, no history of gall-stones. The patient was much relieved by each tapping, and apparently recovered from her illness, but the ascites always reappeared after a varying interval. A fourth operation also afforded great relief, but four days afterward she had a rigor, which was followed by symptoms of peritonitis and death. The autopsy revealed a large amount of dark, turbid liquid in the abdomen. Liver stained of an olive-green color. The gall-bladder was distended by dark bile to the size of a turkey's egg, and extended some distance below the margin of the liver. The cystic and hepatic ducts were much dilated, the dilatation of the hepatic ducts extending into the interior of the liver. The common duct was obstructed by a fibrous thickening of the coats. It was evident from the lesions that the jaundice was a direct mechanical result of the constricted gall-duct; the ascites an indirect result. It is interesting to note that, although the last tapping, when the strength of the patient had been much impaired, was followed by peritonitis, the previous three tappings not only afforded great relief, but unquestionably prolonged her life in comfort for several months.

A Case of Fatty Growths in the Right Auricle.—Dr. Lewis Schooler, of Nevada, Iowa, reports a case of fatty tumors of the right auricle in *Gaillard's Medical Journal* for August, 1880, with the following history: Patient, female, æt. 22 years, had suffered from dyspnœa and palpitation in the recumbent posture, but in the upright position she experienced scarcely any difficulty. The doctor found her in bed, with pale countenance, eyes closed, breathing stertorous, pulse irregular, sometimes beating regularly for a few seconds, and then there would be total absence of the pulse from the radial artery for a few seconds. Patient was unconscious and evidently dying; auscultation over the region of the heart showed the contractions of that organ to be regular; when the pulse was felt at the wrist the sounds were normal, and when the pulse was absent at wrist the sounds were scarcely discernible. Patient died in a few minutes. *Autopsy.*—Body presented all the appearances of one who had died suddenly while in good health. Brain normal, with slight congestion of the cerebellum. The right auricle was found to be greatly enlarged, and of a very dark, almost black color, so great was the venous congestion. On opening the right auricle the cavity was found to be almost completely filled with two separate fatty tumors; the largest was of oblong form and measured an inch and three-fourths in length by an inch and one-fourth in width, and about three-fourths of an inch in thickness; the smaller one was ovoid in shape, and was about three-fourths of an inch in all its diameters. The larger one was attached to the right over the entrance of the vena cava, and the smaller was attached to the left of the vena cava, and to the septum between the auricles. Both were easily detached without any injury to the wall of the auricle. On the under surface of the tumors there was adherent about two ounces of coagulated blood; and to the upper portion of the larger tumor there was adherent a semi-transparent gelatinous substance which extended into the vena cava about three inches, and was about one-third larger than a lead-pencil.

A New Operation for the Radical Cure of Hydrocele.—Dr. Bernard Bartow read a paper upon this subject before the Buffalo Medical Club, April 28, 1880. The operation consists of an incision from three to four inches in length, in the scrotum—in the centre of the hydrocele tumor—extending through the scrotal tissues until the sac is exposed. The loose connective tissue is then separated from the sac to the extent of about an inch on either side of the line of the incision, exposing about one-third the circumference of the tumor; the distended sac protruding into the wound renders this last step very easy of accomplishment. Into the most depending part of the tumor thus exposed, a fine trochar and canula are introduced, and the fluid is drawn off, the entire wound being left to close by granulation. It is intended that air shall not be admitted into the sac, and it is preferable to make the incision with antiseptic precautions, and to continue them during its subsequent treatment. Of the two cases where this plan was used, the first was a large hydrocele that had received no previous treatment, the second case being one in which repeated tapping had been performed. The clinical features following the operation were very similar to those following the injection of the sac with tr. iodine. At the end of nine months there was no sign of a return of the disease. Following the operation in both cases, the testicle was movable in its sac, showing that obliteration of the sac did not take place. The recommendation of this operation is based upon the fact that it is free from the dangerous constitutional disturbance which is liable to follow inflammation in an open serous sac—as in the case where a hydrocele is incised; and the prolonged suppuration attending obliteration of the sac by incision is superseded by that which would follow from a superficial wound only. By preventing access of air to the interior of the sac, the liability to suppuration within the sac is almost nil; this principal danger being avoided, the method would seem to possess the conditions by which inflammation could be excited with safety in the sac and surrounding tissues.—*Buffalo Medica Journal.*

The Microphone and Dreams applied to the Diagnosis of Disease in the State of Incubation, is the title of a paper by Dr. M. Macario, published in the *Nice médical.* The exaggeration of sound produced by the microphone is said to be so great that the steps of a fly sound like the galloping of a horse, and the author expresses the hope that some application may be made of the instrument in the future, in reference to medicine; his idea being that we may with its help succeed in hearing the sound produced by the molecular movements and in distinguishing between those produced in health and in latent pathological processes. If this hope were realized, we might be able to stifle and strangle in their birth a number of diseases which are now only recognized when their ravages are already far advanced. He has been led to think that this result may be obtained, by the fact that evidences of latent pathological work are sometimes obtained in dreams. Certain dreams, he claims, may be looked upon as precursory signs of an undeveloped malady still in a state of incubation. This fact is demonstrated by such examples as those of Arnaud de Villeneuve, who dreamed that he was bitten in the leg by a dog, and a few days later an anthrax developed at the same place. Galien speaks of a man who in a dream saw himself walking with a stone leg, and a short time afterward the same leg was stricken with paralysis. Hippocrates, in his *Treatise on Dreams*, says that imagining oneself crossing rivers, battling with enemies, gazing at armed men, hideous and terrifying objects etc., is the forerunner of madness. This is verified at the present day by many practitioners, who have made the study of nervous diseases a specialty. Sanguinary congestion and certain hemorrhages are frequently announced by peculiar and characteristic dreams. Other remarkable cases are cited to prove that if these dreams are repeated often, we may consider them as precursory signs of a more or less serious affection. Now, if certain dreams can make evident pathological conditions which are still latent, and which are working their way in the depths of the organs of the system, it is simply owing to the fact that a molecular movement imperceptible to our limited sensibilities is passing in these organs, and the writer asks, inasmuch as the microphone is to the ear what the microscope is to the eye, why may not we expect to obtain with it analogous results?—*Gaillard's Medical Journal.*

Dilated and Mobile Pupil in Epilepsy.—Dr. L. C. Gray draws attention to the diagnostic significance of a dilated and mobile pupil in epilepsy. He regards it as a symptom of importance, and states that by means of it he has been enabled to make a diagnosis in several instances where the history of the attack was uncertain. He describes it as a pupil which changes from contraction in a bright light to dilatation in a shaded light much more quickly than the normal pupil, sometimes instantaneously, undergoing the changes from dilatation to contraction with the same facility, and which is, moreover, moderately dilated even in a bright light. An examination of forty-nine epileptics was made at the Flatbush and other institutions, and in all but four of these the pupil had the characteristics described. These observations apply only to cases of functional epilepsy. The mobility and dilatation were usually in proportion to the inveteracy and violence of the disease, although not always so. The cases of *petit mal* exhibited this phenomenon in a marked degree.—*Amer. Journ. of Med. Sci.*, Oct., 1880.

A New Reagent for the Detection of Biliary Coloring Matter in the Urine.—M. Masset describes in the *Archives médicales Belges* a new method of testing for bile, which is calculated to be of service at the onset of certain diseases. Two grammes of the urine to be examined are placed in a test-tube, and acidified with two or three drops of concentrated sulphuric acid; a small crystal of *nitrate of potassium* is then dropped in in such a way that it reaches the urine at the bottom without touching the sides of the tube. If the proportion of biliary matter in the urine be large, its presence is at once indicated by the appearance of streaks of a magnificent grass-green coloration; on shaking the tube this coloration becomes uniform and of a deeper shade of green; it is unaffected by boiling, and remains unaltered for several days. If the quantity of biliary principles is extremely small, the liquid in a very short time acquires a pale green hue, which is as lasting as the deeper shades. This coloration is easily detected by holding up the tube between the eye and the light, or on looking vertically through the tube and urine against a white background. Normal urine so treated takes on a light rose-colored tint.—*Bulletin gén. de thérap.*, July, 1880.

Electricity in Lead Colic.—Dr. Rothe, of Alterburg, reports the following case: A man employed in a type foundry recently consulted him on account of obstinate constipation, which had lasted three days and was associated with severe colicky pains. Purgatives had failed to produce the desired effect. A hypodermic injection of morphine was immediately given, and an emulsion ordered containing ten drops of croton-oil to four ounces of castor-oil, a tablespoonful to be taken every hour. After a sleepless night the patient was found in the same condition. A rectal evacuation had not taken place. Several tablespoonfuls of the emulsion had been vomited. A new drastic purgative also produced no effect, and similar negative results attended other attempts to obtain an action of the bowels. Dr. Rothe then determined to use the faradic current to relieve the spasm and obtain peristalsis. One electrode with an olive-shaped point was introduced high up into the rectum, and the other armed with a rather large sponge was applied over the abdomen and to the lumbar vertebræ. During the ten minutes of application violent contractions of the abdominal muscles occurred, and the patient also complained of severe pains. They soon ceased, however, after discontinuance of the electricity. On the following morning the patient was found to be completely relieved of his former troubles, and stated that a very copious rectal evacuation had taken place very shortly after the use of the faradic current.—*Memorabilien Monatsch. f. prakt. Aerzte*, Aug. 31, 1880.

Flaccidity of the Iris in Real Death.—Mr. Joll, of London, draws attention to the fact that the condition of the iris furnishes a reliable means of determining the question of real or apparent death. In real death the iris is in a state of complete flaccidity. This can be easily shown by synchronous compression of the globe of the eye in two opposite directions, when the pupil will readily assume an oval or irregular shape, whereas in cases of apparent death no ordinary amount of compression in this manner will have the least effect in altering the usual circular form of the pupil. This sign is especially valuable because it is found before the cooling of the body, and before the supervention of rigor mortis. Mr. Joll states that the value of this sign was first pointed out by M. Ripault.—*British Med. Jour.*, Sept. 25, 1880.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, November 20, 1880.

HOSPITAL MANAGEMENT.

All such as are interested in studying the principles of hospital management will watch with interest the growing complications in the Guy's Hospital affair. From all appearances it is, if possible, farther than ever from any equitable adjustment of the respective rights and privileges of the medical staff and the governing board. The stand which was taken by the medical staff—perfectly proper, on the principle that anything pertaining to the medical management of the hospital should be left to medical men—has been not only yielded to the managers, but a virtual apology has been offered to them by some members of the staff for holding such opinions. There has been no doubt a great deal of indiscreet letter-writing in which passionate expressions have taken the place of calm reasoning, and in which motives rather than principles have been largely discussed, but an apology for wrong-doing in those directions was all that could have been reasonably required of dignified gentlemen. But we imagine that it will be hard for the profession to understand why, on the trivial pretence of preserving servile positions, of protecting what are thought to be the interests of a medical school, the medical staff should yield a principle that was practically unassailable, and should virtually acknowledge that even in the medical management of a hospital they have no rights. In all the history of hospital mismanagement, in the record of all the quarrels which have ever taken place between the medical and lay boards of such institutions, there is no more humiliating spectacle of abject truckling to expediency than is presented to the medical world by some of the medical staff of Guy's. The lay board in the hospital, taking advantage of the situation, have shown renewed courage in declaring that the power is entirely in their hands and that the staff must in future behave with becoming respect to such authority. Thus the matter stands at present, and the staff have the melancholy satisfaction of knowing that they have not only lost a grand opportunity of settling a great question, but have compromised their influence with their brethren to the extent of never being trusted again in any emergency requiring cool judgment, self-respect, and moral fortitude. There was no more favorable opportunity than has been offered by this discussion to open the eyes of the public concerning the objectionable features of the lay management of some hospitals, and to bring about the necessary reforms. But, for the present, such an opportunity has been lost to the profession by the surprising action of the medical staff of the hospital in question. It would have been far better for this staff never to have touched upon the question of rights, to have suffered their infringement in silence, than to have invited public discussion concerning them, only in the end to advertise a weakness to the world, which is the more deplorable because inexcusable. There is now a hope that the charter of the hospital may be altered to prevent too much lay interference in future; but what would have been comparatively easy before the back-down of the staff, will now be likely to be attended with great difficulty. The only hope now left to the friends of the sick poor, for whom the hospital was primarily intended, is that the staff will not destroy a last chance by another ignominious apology.

It was very unfortunate that the governors should have insisted in changing the nursing system of the hospital without consulting the staff, but still worse was it for the staff, after complaining, as it had a right to do, of such interference, not only to change its views, but to ask forgiveness for having held them.

PROGRESS OF PSYCHIATRY IN THIS COUNTRY.

In February, 1880, Dr. J. C. Shaw, Medical Superintendent of the King's County Insane Asylum, burned all the camisoles, wristlets, strait-jackets, and other forms of restraining apparatus in his institution. Dr. Shaw did not, in the Byronic matter, awake the next morning and find himself famous; but he did, nevertheless, perform an act which will make his name historic among alienists, since he now stands as the first American physician to do away entirely with mechanical restraint in the treatment of the insane.

The significance of Dr. Shaw's (in a very literal sense) burnt offering to psychiatry and liberty was very forcibly brought out at the meeting of the Society for the Protection of the Insane and the Prevention of Insanity, an account of which is given elsewhere in this issue. The remarks and discussion on that occasion tended, in general, to furnish the audience with a view of the condition of psychiatry in

Europe as compared with that in America. It was shown beyond all cavil that American insane asylums and the American methods of caring for the insane, are at present behind those of Europe. Some of the special deficiencies of our system mentioned were, the large asylum buildings, the lack of central supervision, the interference of politics with executive management, the too great use of mechanical restraints, and the absence of systematic employment of patients. It was because a radical method had been applied, in the King's County Asylum, for the relief of the last two deficiencies, that its superintendent received such prominent notice and commendation. But, though Dr. Shaw has done something for psychiatry and the insane, there is a great deal still to be effected. The sociologist in this country finds himself confronted with two indubitably established facts. The one is that insanity is increasing faster, proportionately, than the population, and faster probably than it increases in some, if not all, other civilized countries.

The other fact is that the management of the insane, as a whole, is worse here than it is in the leading European countries, and is eminently behind the age. This condition of things does not imply that much has not been done to help our insane, or that we have not humane and skilful alienists among us. But it does show that some further earnest work is demanded, and it is in response to such demand that the association has been organized whose recent meeting we chronicle. Radical reform can only come when the people see its need and call for it. There must, therefore, be organized effort to instruct the people, and this is one of the ends toward which the association in question intends to direct itself.

At the same time it must be shown in what particular ways a reform can be obtained, and upon this point nothing could be more wise or practical than the remarks of the Rev. Arthur Brooks in his plea for breaking up the present union of politics with the administration of charities. There are plenty of illustrations of the injuriousness of this union, but none more striking than the fact, which is currently reported, that one of the State Asylum superintendents has been working all the past summer to secure the failure of the investigation now being made by a Senate Committee into the condition of the state insane.

But while public feeling is being thus aroused and properly directed, something can meanwhile be done by urging all possible improvements in asylums as they now exist. This has been illustrated by the work of Dr. Shaw.

Taking it altogether, there is great reason to believe that we shall before long see much advance in the care and treatment of our insane. The interest in the subject is steadily increasing, and reaches both medical men and the laity. The National Association has an extensive and increasing membership of a character which commands respect, and insures a constant activity; and constant agitation means ultimate success.

ACTS AND ORDINANCES TO REGULATE THE SALE OF POISONS IN THE CITY AND COUNTY OF NEW YORK.

An Act, that of 1872, is in force, § 7 of which declares: "It shall be unlawful for any person from and after June 1, 1872, to retail any poison enumerated in Schedules A and B, as follows to wit:

"*Schedule A.*—Arsenic and its preparations, corrosive sublimate, white and red precipitate, biniodide of mercury, cyanide of potassium, hydrocyanic acid, strychnia, and all other poisonous vegetable alkaloids and their salts, essential oil of bitter almonds, opium and its preparations, except paregoric and other preparations of opium containing less than two grains to the ounce."

"*Schedule B.*—Aconite, belladonna, colchicum, conium, nux vomica, henbane, savin, ergot, cotton-root, cantharides, creosote, digitalis, and their pharmaceutical preparations; croton-oil, chloroform, chloral, sulphate of zinc, mineral acids, carbolic and oxalic acids, without distinctly labelling the bottle, box, vessel, or paper in which said poison is contained, Poison."

"The provisions of these sections shall not apply to the dispensing of poisons *in not unusual quantities or doses, upon the prescriptions of practitioners of medicine.* And nothing shall apply to, or interfere with the business of any practitioner of medicine who does not keep open shop for the retailing of medicines and poisons; nor with the business of wholesale dealers, except by § 7, and the penalties for its violation."

It will be seen by this act, if a physician prescribes unusual quantities or doses of poisons, the apothecary is called upon to put a poison label upon the bottle, box, or paper, etc., containing the medicine so prescribed.

It must be admitted that physicians sometimes order large doses of active medicine, generally by design, sometimes by mistake, and that the public is entitled to protection in this direction, and some pharmacists, instead of putting on a poison label, wisely and kindly use a cautionary one, viz.: "Use only as directed; Take care in measuring the doses; or, Use with care." In the German pharmacopœia there is a table A, of eighty-six medicines, designating the largest doses for an adult, which the physician must not exceed in his prescription when intended for internal use, unless he adds an exclamation point (!) as a sign to the apothecary that he is fully aware what he is prescribing, and has made no mistake; otherwise the apothecary is compelled by law to refuse to put up and dispense the prescription.

Would it not be well for our physicians to adopt a like method, and also to order labels : *To be used with care* ; or, *To be used only as directed* ; or, *Take care in measuring the doses*, etc.

Comparatively few mistakes are made by learned physicians and skilled pharmacists; still, a few do occur and create great excitement in the public mind. So great has this grown from late occurrences—notably one at Long Branch—that the Common Council of New York are, or were, on the point of passing a most mischievous ordinance, ordering every apothecary to put a poison label upon all prescriptions of physicians containing " arsenic, aconite, belladonna, conium, gelseminum, nux vomica, opium, hyoscyamus, stramonium, veratrum viride, and all medicinal substances composed of them, wholly or in part, or derived from them; corrosive sublimate, biniodide of mercury, hydrocyanic acid, all cyanides, oil of bitter almonds, oxalic acid, phosphorus, and veratria, and all compounds and preparations of these substances."

We have learned that the above list was given to the Committee on Law of the Common Council by a well-known physician, whose name often appears appended to certificates for proprietary articles, interviews with reporters, etc., etc. He cannot be accused of ignorance, but carelessness or mischief toward the Common Council and to the medical profession may be perhaps inferred. In the first place, many of the compounds of phosphorus, such as the phosphates of soda and iron, are almost inert, and the phosphites and hypophosphites, and the numberless syrups composed of them, are not poisonous. In the second place, it would be very difficult to kill any person with any preparation of hyoscyamus, except hyoscyamia. The same holds true of belladonna and conium. Digitalis, colchicum, and lobelia are far more dangerous. In the third place, the smallest quantities of the interdicted medicines must be labelled *poison* by the apothecary, from the thirtieth dilution of the homœopathist up; while physicians generally prescribe these medicines in such small doses that they are no longer poisons.

We understand that Dr. John C. Peters took the stand before the Law Committee of the Common Council that the ordinance was not only a reproach and injury to the medical profession, but was aimed in the wrong direction if it was intended to protect the public, as more poisons were dispensed in the shape of secret, proprietary, and patent medicines, than from physicians' prescriptions ; that even a celebrated soothing-syrup had caused death, and was generally supposed to contain morphine ; that almost all secret and patented cough-syrups contained opium in some shape ; that most of the hair-dyes contained lead and were poisonous, and under the latter should be enumerated all patented worm-lozenges, lung-balsams, blood-purifiers, cough-candies, carminatives, teething cordials — Godfrey's, Dalby's ; heart-correctors, cough-drops, worm-drops, invigorating drops, elixirs, including McMunn's, were poisonous. Dr. Peters insisted that all these patented and proprietary articles were more worthy of having poison labels upon them than physicians' prescriptions containing the same articles. Also very many of the pills, powders, etc., made by the great manufacturing druggists ; and last, not least, all the prescriptions which are duplicated by apothecaries without special directions from the physicians, which are even dispensed to others for whom they had never been prescribed.

Reports of Societies.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, October 27, 1880.

DR. T. E. SATTERTHWAITE, PRESIDENT, IN THE CHAIR.

DR. CARPENTER reported, on behalf of the Miscroscopical Committee, that the heart presented at the last meeting by Dr. Briddon was the seat of fatty degeneration and that the deposit was calcareous rather than osseous. The breast, also presented by Dr. Briddon, was a specimen of ordinary carcinoma.

DR. SATTERTHWAITE presented a specimen of fibrinous pericarditis, cirrhotic kidney, and chronic diffuse nephritis, on behalf of a candidate for admission to the Society.

ATONY OF BLADDER—CONGESTED MUCOUS MEMBRANE.

DR. W. M. CARPENTER presented a section from the anterior wall of the bladder of a man, aged twenty-eight years, who had been under medical observation as a patient for nine days before his death in Bellevue Hospital. At the post-mortem examination the bladder was found overdistended with urine, containing about thirty-eight ounces of this fluid. The man was reported to have passed the normal quantity of water, and attention was not particularly directed to the bladder. On opening the latter and removing the urine, a condition of the mucous membrane was discovered which seemed to have a bearing upon the possible occurrence of cystorrhagia. The entire surface of the membrane was intensely injected. Dr. C. thought that, in case the bladder had been suddenly evacuated and the pressure of urine thereby removed from the injected vessels, cystorrhagia would have occurred. The patient, at the time of admission, was suffering from phthisis. His body presented a museum of pathological specimens. The lungs, too, contained miliary tubercles, and there was a cavity in the left apex. The liver was large and probably fatty. There was the large white kidney on both sides. The right of these organs was thickly studded with tubercles. There were no tubercles in the walls of the bladder. The urethra was not the seat of stricture, and there had been no purely mechanical impediment to the flow of urine. The ureters were moderately dilated, probably due to the setting back of the urine from the overdistended bladder. The urine was one-third albuminous. No examination was made for casts. The immediate cause of death was uræmic coma.

Dr. Post asked if atony of the bladder at that age was not a very unusual condition. Also if it were possible that a paralysis of a central organ could exist without a corresponding paralysis of the extremities.

Dr. Carpenter stated that he had seen retention of urine apparently from simple atony of the bladder, in a patient aged sixteen years. This condition existed a week, requiring catheterization during that period.

Dr. Post thought that such a case might be regarded as one of spasmodic retention, as occurs in hysterical females. In this connection he referred to a similar one which occurred to him while house surgeon of the New York Hospital. The patient was a female, who, if not relieved by catheterization three times daily would develop symptoms, which simulated those of peritonitis, for the relief of which blood-letting appeared to be the only remedy.

Dr. Carpenter remarked that there was no special nervous element in his case.

Dr. Sell referred to the case of a young married man, who was unable to pass his water in any one's presence, and when on jury duty would suffer from retention because he would be accompanied to the closet by an attendant of the court.

Dr. Satterthwaite remarked that the bladder was very often found full at a post-mortem examination. As he understood it, the point made by Dr. Post was whether there could be any paralysis of the muscular coat of the bladder without a general paralysis of the lower extremities.

Dr. Carpenter supposed it was well recognized that retention of urine was common when the bladder was simply overdistended.

Dr. Post remarked that such a state of things was due to atony, but not to paralysis.

Dr. Lange asked if the stagnation of blood in the mucous membrane of the bladder was due to the removal of the pressure of the urine or to inflammatory action.

Dr. Carpenter thought that it was from the removal of pressure.

Dr. Lange believed that the acceptance of such a view depended entirely upon the thickness of the walls of the bladder.

Dr. Briddon stated that this sudden removal of pressure from the blood-vessels and the consequent varicose condition thereby invited were, according to some authorities, the explanation for the shock which occurs when the overdistended bladder is suddenly evacuated.

THE PATHOLOGY OF DYSMENORRHŒA.

Dr. Tausky presented a specimen of dysmenorrhæl membrane discharged by a young lady aged nineteen years. She commenced to menstruate at fourteen years of age, and continued to do so regularly without discomfort until her seventeenth year, when she began to suffer from excruciating uterine pains. At each of these attacks she would pass membranes such as the one exhibited. He remarked that he had met with but one case similar to the above, and presented the specimen on account of its rarity. A microscopical examination would be made by Dr. Heitzmann.

Dr. Putnam-Jacobi remarked that the pathology of membranous dysmenorrhœa had received a great deal of light from the researches of Drs. George and Frances Haggan, of England, who published an article on the subject in the *Archiv für Gynækologie* some three years ago. They found in the uterine mucous membrane of all the mammalian animals which they examined, a "deposit" of embryonic tissue existing under the epithelium. To the formative activity of this tissue was due the development of the mucous membrane at the beginning of pregnancy. She had occasion to study it in the uterus of rabbits. A lesser degree of formative activity in this same tissue than is aroused in pregnancy provides for the production of the superficial layers of mucous membrane which desquamate in menstruation. In endometritis, as in other inflammations, this embryonic tissue was in excess—a fact which explained many, if not all, the symptoms of the disease. A continuous succession of stages might be traced from the thickened mucous membrane of ordinary endometritis to that degree of excess in the paroxysmal formative activity of the embryonic tissue, which led to the development of a membrane necessarily extended as a foreign body as soon as its growth was arrested by termination of the paroxysm.

The Drs. Haggan believed that the nervous influences presiding over that plastic process emanated from the same source in the case of the dysmenorrhœal and of the normal decidua, namely, from the ovary. Membranous dysmenorrhœa was a highly exaggerated endometritis, dependent ultimately upon a special form of ovarian irritation, in which the most characteristic function of the ovarian nerves was called into play by an abnormal instead of a normal stimulus.

Dr. Ripley referred to a case in his practice in which a dysmenorrhœal membrane was thrown off, and in which he dilated the cervix a week before the menstrual period, and applied to the mucous membrane of the uterus an eighty-grain solution of iodine. This plan of treatment resulted only in the prevention of the discharge of dysmenorrhœal membrane in the following menstruation. Dr. Sims had advised the application of strong nitric acid to the mucous membrane, but this advice was not followed.

Dr. Putnam-Jacobi remarked that, theoretically speaking, there appeared to be an impropriety in such a plan of treatment as carried out by Dr. Ripley. It seemed to her that an excessive development of the embryonic tissue would be invited thereby, and besides, in the pre-menstrual period such applications were apt to be followed by dangerous consequences.

Dr. Ripley replied that at the time he used the application he did not know that there were any settled views in regard to the pathology of the affection. In that particular case no bad result followed the application. He was not quite certain that there was any special danger in making such applications during the pre-menstrual week. On the contrary, he believed that the danger was especially great in making such applications the week after menstruation, as at that time the uterine mucous membrane was, so to speak, more exposed.

Dr. Putnam-Jacobi remarked that an extended observation in a large number of cases had proved that after the menstrual period the whole uterus was in a quiescent state. In this connection she referred to a case in which, by some misunderstanding as to the time of menstruation, she had made an application to the uterus a week preceding the period, and that metritis was the result. She was strongly convinced that the occurrence of many cases of metritis was due to the fact that the difference between making applications during the pre- and post-menstrual periods was not taken into account.

Dr. Ripley replied that it was a very common practice to dilate the cervix just before menstruation and make applications to the uterus, and that such a practice was not, as a rule, followed by bad results. In cases of sterility with narrow cervix, the latter was dilated with a sponge-tent, which was introduced during the pre-menstrual period and allowed to remain for some time in direct contact with the mucous membrane of the cervix and fundus. This latter practice had been adopted by the best men of the city, at least up to a very recent date.

THE TREATMENT FOR TAPE-WORM.

Dr. Tausky presented a second specimen, which consisted of the head of a tænia solium. The interest in the same centred in the fact that this part of the worm was, on account of its small size, seldom found in the stools. In connection with the specimen he described his plan of treatment for tapeworm as follows: three ounces of the pomegranate root is soaked for twenty-four hours in eight ounces of water. This was then boiled down to three ounces, to which were added three ounces of the etherial extract of male fern, one and one-half drachm of sulphuric ether, two drachms of fluid extract of valerian, one drop of croton-oil, and one and one-half ounce of honey. The patient then abstained from all food, save herrings and onions, and also from water.

Dose: One-third every half-hour, as soon as the patient felt intestinal contractions or colic, whether this was after the first, the second, or third dose. One ounce of castor-oil was administered hourly, in cold, black coffee, without sugar, until the worm was expelled. In case the vermicide mixture caused nausea, lemonade, ice-pills, or strong, cold, black coffee without sugar, relieved it. The preparatory treatment was a dose of castor-oil forty-eight hours before taking the worm-medicine, so as to empty the bowels thoroughly of fæces. Milk diet exclusively for twenty-four hours following the laxative, and the twenty-four hours before taking the mixture the patient abstained from food and drink, except that he occasionally took a little salad, made up of salt herring, onions, and garlic. After the worm was expelled, mucilaginous food only was taken for a day or two, and a starch and laudanum enema in case of tenesmus.

Dr. Sell remarked that he had had the same success with virtually the same kind of prescription.

Dr. Van Giesen asked if any of the members had had experience with the aspidium marginale in these cases. The herb belonged to the same family as the male fern, and was indigenous. He had used it in a single case, but did not succeed in bringing away the head, at least he did not find the latter. The time for collecting the aspidium was during the fall, just before the tops began to die. After allowing it to dry for a few weeks, it could then be treated the same as the roots of the male fern.

Dr. Carpenter called attention to a report on this drug made by a member of the State Pharmaceutical Association at the recent meeting of that body, as published in the Medical Record. The report was to the effect that the vermifuge was equally efficacious with the male fern.

Dr. Lewis Smith stated that it was the custom, in treating cases of tænia in the children's out-door department of Bellevue Hospital, to give them as large doses as usually prescribed for adults. He had never seen any harm following the practice. He thought that the usual dose as given to children was too small.

Dr. Briddon said that he never failed with drachm-doses of male fern. He usually administered the latter in an ounce of olive-oil. Forty-eight hours before the patient took a dose of salts and sennæ; for twenty-four hours before, beef-tea only; twelve hours before, a dose of castor-oil, and then the vermifuge the morning afterward.

HEART-CLOT AND SACCULATED ANEURISM.

Dr. Van Giesen presented a specimen thought to contain an ante-mortem heart-clot. He had not seen the patient during life, and the specimen was brought to him by Dr. Fulda, of Brooklyn, the attending physician. The patient, a man aged twenty-five years, first applied to Dr. Fulda, August 2d, for the relief of extreme dyspnœa. The latter was his only symptom. He had had a previous attack on July 4th, and also one seven years previously.

On physical exploration of the chest the apex-beat of the heart was found two inches below the normal level and nearer to the median line. There was a mitral murmur with various bronchial sounds over both lungs. Area of precordial dulness was very much increased. Dr. Sanford, who was called in consultation, detected an aortic murmur. The diagnosis was cardiac dilatation. The man died August 9th. A limited autopsy only was made. At the autopsy a heart-clot of considerable firmness, but with no prints of the valves, was found in the left ventricle. The mitral and aortic valves were insufficient, and there was a commencing sacculated aneurism of the ascending aorta.

ECBOLIC EFFECT OF STRYCHNIA.

Dr. J. Lewis Smith presented a specimen with the following history: On October 11th a plethoric and robust German woman, about eight months advanced in her first pregnancy, according to our reckoning, called at my office for treatment. She stated that her only ailment was numbness of the fingers of both hands, and a pricking sensation in them as if they were asleep. Her pulse was strong and regular, her features rather florid and of healthy aspect, and her temperature apparently normal. Her urine, obtained two days subsequently, was found free from albumen.

Two remedies were prescribed, namely: citrate of magnesia, on account of her plethoric state, although there was no constipation, and $\frac{1}{30}$ or $\frac{1}{32}$ part of a grain of strychnia in sugar-coated pill three times daily. On the following day the medicine was taken as directed, and the bowels were opened. She took three doses of the strychnia, with an interval of six hours between the doses, in all one-tenth of a grain. The following night was passed comfortably, the numbness and pricking of the fingers having ceased; but about eight o'clock on the following morning, before another dose of the medicine had been taken, unexpected symptoms of uterine contraction commenced. Several hours elapsed before I was called. The pains were different from those of ordinary labor. They were more persistent, so that nearly half the time her breathing was accompanied by a low moan. The pain at first had been felt in the upper part, or fundus of the uterus, near the epigastrium, but it gradually extended over the entire organ. It was not felt at all, or was felt but slightly in the back. The uterus, examined through the abdominal walls, seemed firm as if its muscular fibres were in a state of moderate tonic contraction, and the os uteri, examined per vaginam at different times through the day, was closed and uniformly rigid. The uterine contractions had no effect in dilating it.

At my first visit the pulse was natural and surface cool, but in a few hours the surface became hot, the face flushed, and the pulse rose to 108 per minute and was full. During this time of febrile movement there was occasional vomiting, and the entire uterus was tender on pressure. The symptoms, indeed, bore considerable resemblance to those of incipient peritonitis of mild form, but the temperature after the pain had begun to abate I found nearly normal.

In the afternoon of the 13th, being satisfied that the pains were not those of normal labor, I prescribed a mixture, containing the deodorized tincture of opium and camphor, but the doses were vomited, and therefore seemed to have little effect. The night of the 13th was passed without sleep and in pain, but early in the following morning I prescribed powders of sulphate of morphia, which were retained and in the course of a few hours produced entire relief of symptoms.

During the next twenty-four hours no pains occurred, namely, from the morning of the 14th to that of the 15th. The uterine tenderness gradually abated, the os uteri had apparently undergone no change, and it seemed probable that the full term of gestation would be completed. However, on the morning of the 15th the pains returned, but this time with more distinct intermissions, and normal in their nature, and in the following evening the child was born. Nothing unusual occurred during the labor, and the mother has made a good recovery.

The infant presented the appearance of prematurity, would not nurse from the nipple of the mother, but nursed from an artificial nipple (Neidlinger's) applied over that of the mother. It had no lividity, its respiration was normal, its cries strong. It had a scanty growth of hair, and its nails were developed. Its evacuations also were normal. But by the second or third day it began to be icteric, and before its death became much so, the urine producing a deep yellow stain in the diaper. In the afternoon of the fifth day it refused to nurse, and was perhaps somewhat weaker. It was not supposed, however, to be in any immediate danger, and it was as usual placed upon its side, at a little distance from the mother, in the same bed. After a little time the nurse examining it found it dead. The point of chief interest in this case was the apparent causative relation of the strychnia to the miscarriage. It would seem from this case that strychnia should, like large doses of quinine, be one of the forbidden remedies for pregnant women; and the interesting question arises whether nux vomica, now recommended by the highest authorities for the nausea of pregnant women, should not be used with caution.

There was nothing of special interest in the jaundice, as it is common in the new-born, especially the weakly and premature. The explanation of its occurrence, which I think is generally accepted by the profession, is that given by Frerich and others, namely, that its cause is not catarrhal, as in the ordinary form of icterus, but that it originates from the diminished fulness and tension of the blood-vessels within the liver consequent on ligature of the cord and the cutting off of the supply of blood through the umbilical vein. For, if immediately after birth the circulation be for any reason feeble, as in premature infants, and the tension of the blood-vessels within and around the hepatic lobules be diminished, a part of the bile produced in the hepatic cells would, by the law of diffusion, enter these vessels instead of the bile-ducts, and the presence of bile in the blood in notable quantity is all that is required to cause jaundice.

Permission was obtained to examine the heart and lungs of the infant. The heart seemed normal, there being the usual valvular spring of the foramen ovale. The left cavities were empty, while the right contained considerable dark fluid blood. The lungs were dark, collapsed, and non-crepitant. They resembled in appearance the fetal lungs, although the infant during its short lifetime had cried vigorously, and its respiration had been normal. It seemed that the contractility of the lungs had expelled nearly all the air which it had contained.

Dr. Putnam-Jacobi, in connection with the symptom of paræsthesia, as manifested in the patient, expressed the opinion that it was doubtless connected with the nervous phenomena of pregnancy. In other cases it was associated with a gouty diathesis, and simple anæmia; Dr. Putnam, of Boston, had presented a paper on this subject in which he had collected twenty-five or thirty cases of paræsthesia. He was unable to find the evidences of central lesion in any of them. Dr. Gibney had seen three similar cases and he did not believe that any treatment was available. A possible exception to this rule was that of a strong, robust man, who was greatly annoyed by paræsthesia of the ulnar aspect of the forearms. In that case actual cautery over the entire area of paræsthesia was attended with a good result.

Dr. Van Giesen stated that of four cases of paræsthesia he had seen within the past eighteen months, two were evidently due to malarial influences. Both were permanently cured by quinine and nux vomica. In the other two cases treatment was unavailable.

Dr. Briddon believed that the condition of paræsthesia was dependent upon some of the forms of toxæmia. He had found it most commonly associated with gastro-intestinal disturbances and in the rheumatic and gouty diatheses.

Dr. Putnam-Jacobi thought that strychnine was very liable, in the latter months of pregnancy, to invite premature uterine contractions.

Dr. J. C. Peters was accustomed to give from three to five drops of nux vomica thrice daily for the nausea of pregnancy. He had never seen any bad effects therefrom.

Dr. Ripley remarked that Ringer advised even smaller doses of the same drug for that symptom.

Dr. Peters believed that the doses thus advised were too small to be of real service.

ANEURISM OF MIDDLE CEREBRAL RUPTURING INTO THE LEFT VENTRICLE.

Dr. Ridlon presented an aneurism of the middle cerebral artery with the following history: Peter W——, aged thirty-nine years, Sweden, piano-maker, came under observation December 29, 1879.

Complains of pain and stiffness in back, and headache; feels strong and looks so; appetite good; sleeps well; pulse, 72; temperature, 98.2°; bowels constipated.

Has had rheumatism several times during last fourteen years; present attack has lasted nearly six weeks.

At 3 A. M., January 6th, after passing a comfortable night (the condition having remained unchanged up to this time), patient was found wildly delirious, and with great difficulty was forced back into bed. After an hour he became quiet and breathed heavily. At 8 A. M. he was comatose, breathing stertorously; pupils normal; pulse, 72, full and strong; urine drawn; found to be acid, specific gravity, 1015. Albumen, 15 per cent. No casts.

When seen at 2.30 P.M., respiration, 56; pulse, 130; temperature, 102.8° (axilla). The lines of the left face are less marked than those of the right. Has not moved hand or foot.

January 7th, 8 A.M.—No longer breathing stertorously; conjunctivæ sensitive. Pupils somewhat contracted. Facial muscles react to irritation. Has moved right hand. Choreiform movements of fingers most marked on right side. Respiration, 60; temperature, 101°. Heart-beats, 164. Cannot be counted at the wrist.

At this point it was learned from the patient's friends that sixteen days before he came under observation, following a severe attack of rheumatism, he had suddenly fallen down quite unconscious; that unconsciousness and delirium alternated for ten days. It is not known that there was any paralysis.

At 6 P.M. coma had deepened. Respiration, 48; temperature, 105.5° (axilla); pulse, 200 (?). He died half an hour later.

Autopsy twenty hours after death: rigor mortis well marked. Body fairly nourished. Both lungs firmly adherent all over. Hypostatic congestion exists. Lung-tissue does not sink in water. Heart hypertrophied throughout. Mitral and aortic valves thickened and slightly insufficient. Aorta somewhat atheromatous. Intestines bound down by old adhesions. Kidneys showed slight amount of parenchymatous nephritis. Liver large, fatty, soft, and congested. Spleen soft, pulpy, and of normal size.

The meningeal veins of the brain were distended. No signs of hemorrhage at either convexity or base. On section, the right lateral ventricle was filled with a soft blood clot which extended through the septum lucidum into the anterior horn of the left ventricle. The clot was most firm and darkest in the anterior horn of the right ventricle. Following the clot forward, in the anterior wall of the ventricle, between the anterior cornua and the fissure of Sylvius, was found a small firm mass.

After the anterior half of the right hemisphere had been macerated the arteries were drawn out. About half an inch from the beginning of the middle cerebral artery (right side), where it gives off its first large branch, in the acute angle formed by the artery and its branch was found an aneurism about the size of a white bean. It was ruptured at about the junction of its proximal and middle thirds, the proximal third being empty and collapsed, and the remaining two-thirds capping over a firm yellow clot which seemed of a size to fill the sac. No other aneurisms were found.

VENTRAL HERNIA CONTAINING HYPERTROPHIED OMENTUM.

DR. E. C. WENDT presented a specimen of the above, with the following statement: This case can claim no interest beyond that which naturally belongs to every rare pathological condition. The hernia was found as an accidental complication in an old man who died at the St. Francis Hospital from a disease which had no connection with its presence. The tumor appeared at the junction of the umbilical and right lumbar regions, and somewhat below the umbilicus. It presented the clinical characters of a lipoma, being soft, painless, and freely movable under the skin. Beyond slight mechanical discomfort it had never been the source of trouble to the patient. When the abdomen was opened at the autopsy, the hernial neck was found to be very narrow, and on one lateral half the omentum adhered to it. The hernial sac consisted of attenuated peritoneum with an abundance of subperitoneal fat. The omental contents of the sac differed from the normal omentum, in presenting larger fat lobules. Between the latter numerous adhesions also existed. The site of the hernia corresponded about to the lower linea transversa, but there was no apparent attenuation of the abdominal parietes.

MALIGNANT TUMOR INVOLVING THE UPPER JAW OF A HORSE.

DR. LIAUTARD presented a malignant tumor of the upper jaw of a horse, which was accompanied with a detailed written history: The specimen was obtained from a very valuable animal (Prospero) of great reputation on the trotting turf. The disease was diagnosticated by Dr. L., in May last, when the animal was condemned, but by a mistaken kindness of his master was allowed to die of starvation. Some time in April this animal was stabling in Philadelphia and was noticed to have a little swelling on the right side of the face, under the eye. This increased, and was accompanied by offensive discharge from the nose. He was then shown to a so-called veterinary dentist, who found and extracted a tooth supposed to be decayed, but afterwards found healthy. A favorable prognosis was given, but still the animal grew worse. The swelling increased and the discharge became more abundant and offensive. A veterinarian was then called to see him, who diagnosticated suppuration in the antrum, and trephined him. The tumor was then quite large, soft at spaces, and the opening through the maxillary bone was done with a single scalpel, showing how diseased it already was. At this time Dr. Liautard saw the animal and diagnosticated osteo-sarcoma of the face, and advised him to be destroyed accordingly. At the time when he was about being killed, a veterinarian of some reputation in Philadelphia and another pretended horse-dentist celebrity of New York who were present objected, as in their opinion the animal was suffering with decayed teeth only, and would soon recover if those were removed. Permission for extracting the teeth was granted, and the fourth, fifth, and sixth molars were removed. Only one presented a decayed spot. Then came another horse-dentist, and the horse was trephined on the upper end of the nasal bone through a portion of the turbinated bone, and then sent to the country at his birth-place to complete its recovery, which was at times reported as making fast progress. The animal died on the 22d of September, and the post-mortem proved that death had taken place by starvation, complicated by repeated secondary hemorrhage from the palatine artery of the right side.

The body was much emaciated, stomach contracted, and intestines almost empty, and presenting the usual appearances of death from starvation. The spleen, kidneys, and liver were healthy. Lungs generally healthy, a little emphysematous in the anterior lobe. Pericardium filled with serum. Heart pale, flabby, with post-mortem clots in both ventricles. Large blood-vessels almost empty all through the body. Ganglia of the abdomen and of chest infiltrated; they were saved for microscopic examination.

On removing the skin the tumor was found to be irregular in shape, soft in some places, hard in others. The cavities of the alveola were filled with new growths, somewhat harder, showing on their lower surface the marks of the lower molar teeth. The second cavity, from which a healthy tooth had been recently extracted, was filled with partly masticated food. The palate bone was diseased in its whole extent, and the mucous membrane of the region on the opposite side is separated from the teeth by an accumulation of pus extending more or less into the alveola on that side. Sections being made through the head a little on one side of the median line, showed the septum nasi healthy, and this being taken off, allowed a full view of the nasal cavities. On the right side, in the meatus, in the cavities of the turbinated bones, in the sinuses, were observed several malignant growths of various sizes, extending back into the fauces and closing them. A similar condition, though less marked, was also discovered on the left side.

The diagnosis of cancerous disease was then made, and was proved to be correct by a microscopical examination by Dr. Peabody.

Dr. Post exhibited two specimens, one of which consisted of a tumor of the cheek formed of two cysts, one over the other, and growing respectively into the skin and adipose tissue. A second specimen consisted of a cancerous breast, which presented a remarkable contraction of the nipple and an absence of lobular induration. Both specimens were removed by operation.

FIBRINOUS PERICARDITIS IN THE HORSE, WITH ENORMOUS EFFUSION, ASSOCIATED WITH PURPURA HEMORRHAGICA, AND FOLLOWING THE "EPIZOÖTIC" CATARRH.

Dr. Satterthwaite, in behalf of Dr. W. H. Porter, who was unable to be present, exhibited a gigantic heart with pericardial sac, both of which were covered with a most exuberant growth of villosities, constituting the condition known as "hairy heart."

The mare had been under the charge of Dr. Frank Walton, veterinary surgeon, and the history which he furnished was as follows: Gray mare, aged eighteen months, weighing about 1,200 lbs., was first seen October 11, 1880. She then had marked œdema of both hind extremities, and slight œdema of the fore ones. She had previously suffered from the "epizoötic," though mildly, and it was thought she had recovered. The visible mucous membranes at this first inspection were very much congested, and marked by numerous blotches, indicating extravasations of blood. Temperature, 102.4° F.; pulse, 44; respiration, 15. The animal was now eating well, and the bowels were regular. The symptoms, however, did not improve, and hemorrhagic spots were soon found on the inner sides of the thighs and under the skin in other parts. The diagnosis of *purpura hemorrhagica* had been made.

When next seen the temperature had risen to 104° F., and the pulse had fallen to 42; respiration, 15. The general condition had not improved, and there was a serous oozing from some collections of œdema on the extremities.

On October 15th the mare was found to be failing. The œdema had mounted to the body, and was apparent on the nose, where the characteristic line of demarcation between the serous collections and uninvaded tissue was well seen and sharply defined, as is usual in purpura. The respiration was now 25, and much embarrassed, owing to the external swelling. Temperature was 106° F., pulse, 50. The animal was greatly depressed and debilitated. On October 16th the swelling of the head had become so great that it was almost impossible for the respirations to be carried on. Accordingly, tracheotomy was performed (10 A.M.) by Dr. N. F. Thompson, veterinary surgeon. The asphyxiated condition was at once relieved, and respiration became almost normal in frequency. The appetite also returned. Digitalis was now administered to control the heart and remove the œdema.

On October 20th this object appeared to have been accomplished quite satisfactorily, so on that day the tracheotomy tube was removed. The condition of the animal seemed to be fairly good, though there was great exudation of serum from the posterior extremities, and some ulceration and even sloughing of the skin. This latter unfortunate condition progressed so that the lower parts of the extremities were simply covered with ulcerations. At this time the urine was examined, but though it contained the carbonate and phosphate of lime in abundance, together with some pus, there was no more albumen than would be accounted for by the latter.

The pulse now became very rapid and feeble (80), but the mare continued eating and walking about. Suddenly, at 11 P.M., she fell, and was found to have instantly died. A post-mortem examination was subsequently made by Messrs. Wallace and Frey, students of veterinary medicine.

On removing the sternum the pericardium was found firmly attached to it and to the sternal end of the ribs on the right side, leading at first to the erroneous supposition that it was a case of pleuritic adhesion.

Upon cutting into the pericardial sac it was found to contain an enormous quantity of slightly turbid serous fluid, ranging from nine to twelve gallons. This distended sac had displaced and compressed the right lung much more than the left. The whole inner surface of the pericardium was covered with a thick layer of villous projections on both visceral and parietal surfaces. To the naked eye the heart looked much like an enormous sponge that had been soaked in water. The layers of fibrinous material were neither very thick nor very firmly attached, which would imply that the disease had not existed a long time. The weight of heart with its contained coagula and the pericardium was nineteen pounds, an excess of ten pounds over the weight of a normal empty heart. Under the microscope the villosities were found to be partially organized and contained an abundance of crystals of a brown color, either in rhombic plates or in needles, which latter were often arranged in stellate fashion. The rhombs were regarded as hæmoglobine crystals and the imperfect rosettes as hæmatoidine. The *lungs* were normal, except for œdema and hypostatic congestion. Beneath the mucous membrane of the *stomach*, as well as in other organs, there were numerous hemorrhagic spots. The *spleen* was soft; so also were the *liver* and *kidneys*. These latter were almost diffluent, and on microscopic examination exhibited very granular epithelia, indicating parenchymatous difficulty such as is met with in all diseases where the blood is profoundly infected.

Dr. Satterthwaite observed that, apropos of the connection between epidemic diseases of the lower animals and man, a subject that was now attracting much attention, it was well to know that this disease was thought to be closely allied to another disease in the horse known as *scarlatina*. Indeed, several eminent English veterinary surgeons had thought it impossible always to distinguish between the two. Others again had regarded it as a carbuncular disease of the anthrax or charbon family. Since Copland, according to Williams—one of the most recent systematic writers on veterinary medicine—had stated that scarlatina originated in the horse and had been communicated from him to man and other animals, the disease was worth some serious attention. It could not be said, however, that there was any marked parallelism between scarlatina in the horse and in man.

Still, if we accept the description given by Williams, it would be observed that the petechial eruption, which later is confluent, corresponds to the human type; then œdema is common to both, and so are sloughing of the skin, rheumatism, heart complications, and extravasations of blood. The œdema, however, is not thought to be renal, and the disease is intermittent, or rather remittent, in character, having curious exacerbations. It is also thought to be non-contagious.

This particular disease was *purpura*, and it exhibited the characteristic appearances that have been described. The fibrinous pericarditis was thought to have been excited by the general blood disease.

In answer to a question Dr. Liautard stated that purpura hemorrhagica was a common sequel of the epizoötic and occurred generally as an evidence of a broken-down condition in horses that were kept at work during the progress of the disease. The purpura was the direct cause of death in the large proportion of those cases.

NEW YORK SURGICAL SOCIETY.

Stated Meeting, October 26, 1880.

DR. R. F. WEIR, VICE-PRESIDENT, IN THE CHAIR.

PHARYNGEAL TUMOR (MYXO-SARCOMA).

DR. GEORGE A. PETERS read a paper on pharyngeal tumor, with the notes of four cases. (See p. 565.)

DR. T. M. MARKOE said he had always felt that there was one physiological objection to Trendelenburg's tube. The sensitive portion of the larynx was the orifice of the glottis, and that was the portion into which blood would trickle, create spasm, and delay the operation, and the tube did not provide against the occurrence of that accident. He had uniformly been pleased with the sponge in the throat as a protection against the descent of blood into the larynx.

DR. A. C. POST referred to two cases in which he used the sponge in the throat in tracheotomy *without* the tube, and the method gave results that were entirely satisfactory. The small quantity of blood which did get into the trachea could be readily removed, because there was no tracheotomy-tube to obstruct the manipulation.

With regard to the enucleation of tumors in the buccal cavity, he had had one case in which the growth involved one side of the soft palate, and he was able to enucleate it without difficulty.

DR. MARKOE, in confirmation of the enucleability of these tumors, cited a case in which Dr. Willard Parker, about twenty years ago, in the New York Hospital, removed one situated in the same region referred to by Dr. Post, and he was able to enucleate it without rupture of the sac. Dr. M. thought it could be laid down as a pathological law that these tumors, as a rule, are enucleable.

DR. MCBURNEY stated that he had used the original apparatus of Trendelenburg in two cases of thyrotomy and met with serious difficulties arising from it in both. In one case the expansion was so great that the rubber bag doubled over the end of the canula, and entirely obstructed respiration. In the other case the irritation of the trachea was so great, that it became necessary to remove the tube and proceed with the thyrotomy without any protection at all.

In most of such cases there was not sufficient room to use a very large apparatus, and it was somewhat hazardous to trust to a small sponge. Therefore it was desirable to find some means by which the trachea could be actually plugged without causing irritation. In Dr. Lange's case the trachea was plugged without irritation, and it was done by means of punk or amadou.

DR. LANGE remarked that this material swells when moistened, and that it could be wet and fitted before being applied for use.

DR. WEIR remarked that of these tumors presented in the paper just read, there were three varieties: 1, Palatal; 2, retropharyngeal; and 3, subtonsillar, and of these he thought that the last variety was the rarest. Some time ago he assisted Dr. A. H. Smith in removing a tumor that involved the soft palate, and afterward, in looking up the subject, he found a pamphlet written by Rouyer, in which eleven cases of the same variety were reported—tumors originating in the soft palate. Nearly all of them were glandular in nature, and were easily removed by simply dividing the mucous membrane and enucleating them with the handle of the scalpel.

About a year and a half ago Dr. Knight, of Boston, presented at a meeting of the American Laryngological Society a case of retropharyngeal tumor. His paper embraced some twenty cases of similar tumors, principally sarcomatous in origin. Most of these were enucleable, and displayed only a moderate tendency to recurrence.

With reference to tracheotomy, he yet doubted the innocuousness of this operation in such cases.

In the removal of palatal tumors he regarded Rose's method of hanging the head over the edge of a table as preferable to tracheotomy; and he thought that many of the retropharyngeal tumors could be cured by the same method, for it has been proved that the blood does trickle down the trachea, even where either Trendelenburg's tube or a sponge in the larynx is employed.

DR. POST thought one great objection to Rose's method, if the operation was a prolonged one, was the inability to keep up the anæsthesia.

DR. WEIR remarked that while the anæsthesia could not be maintained so perfectly as with the tracheal tampon and tube, yet the administration of ether could be, from time to time, renewed by the mouth without serious inconvenience.

DR. POST remarked that it was vexatious to be obliged to suspend the administration of the anæsthetic during an operation, and that probably, in most cases, the prolongation of the operation in that way added to its dangers.

DR. WEIR referred to an additional case in which the inflated portion of Trendelenburg's tube descended and projected over the end of the tracheal tube, and thus arrested respiration entirely.

DR. PETERS remarked it was exactly that difficulty which led him to make a modification of the instrument.

DR. MARKOE thought that Rose's position was suitable to certain operations in the buccal cavity, but believed it to be important to *support* the head in the pendent position, and not allow it to hang unsupported.

DR. POST preferred tracheotomy because of the non-necessity of suspending the anæsthetic during the operation.

DR. WEIR said that if McEwen's method was corroborated, the apparent necessity for tracheotomy would be somewhat modified, because this surgeon passed a moderately large tube through the mouth into the larynx. To this a flexible tube could be attached through which anæsthesia could be maintained as in the tracheal tampon.

Dr. Lange remarked it was believed to be possible that some of the retropharyngeal tumors originated in the thyroid gland from misplaced germs. With regard to the discomfort of position, Rose had proposed to introduce, after the patient had been anæsthetized, a rubber tube into the mouth merely, and administer as much chloroform as possible through that tube during the operation. To that end he used an apparatus specially designed for that purpose.

Dr. Markoe suggested that it might answer with chloroform, but not with ether.

FÆCAL FISTULÆ FOLLOWING THE USE OF THE ASPIRATOR.

Dr. A. C. Post narrated a case as follows: A young man came with three fecal fistulæ in the anterior wall of his abdomen, and gave the following history. Nearly two and a half years ago he was suffering from retention of urine arising from urethral stricture, and he applied to some person who called himself a surgeon and who attempted to perform perineal section, but did not succeed in getting access to either the urethra or bladder. He then aspirated; the point at which he introduced the needle was about half way between the pubis and the umbilicus, and, instead of drawing urine, he withdrew only fecal matter. Afterward he introduced the needle lower down and emptied the bladder. The result of the first aspiration had been a permanent fecal fistula. About a year subsequent to the aspiration some secondary inflammation developed which led to the formation of two other sinuses through which fecal matter had been discharged.

CARIES OF THE RIBS.

Dr. Post narrated a second case with the following history: A man presented himself at this clinic with a fistulous opening over the left sterno-clavicular articulation. When a probe was introduced it passed downward and outward about two inches, and then encountered rough bone—probably the first rib. It was the result of a blow received from a man's fist about one year ago. Recently an inflammatory swelling had occurred as low as the third and fourth ribs, and it had begun to soften at one point. He thought it probable that caries of several of the ribs would be found when it was opened. He regarded it as a rather formidable result to follow a blow from the fist.

FUNGOUS GROWTH AT THE UPPER PART OF THE NECK.

Dr. Post narrated a third case, that of a woman fifty-six years of age, who had a swelling at the lower part of the neck, evidently located in the thyroid body, and above that as high as the os hyoides, a fungous mass of the size of a hen's egg, which first appeared as a small swelling *nine* years ago, had gradually increased in size, and finally become ulcerated. Several of the lymphatic glands under the sterno-cleido-mastoid muscle were also enlarged; and that was the feature of the case which led him to regard it as an improper one for an operation. The disease seemed to originate above the thyroid body, and the question was whether disease originating above could extend downward and involve the body itself. The growth did not interfere with respiration.

Dr. Weir remarked that he saw Dr. Post's case of fæcal fistula, and it was extremely interesting from its rarity and on account of its treatment. He also referred to a case, recently presented to the New York Clinical Society by Dr. W. T. Bull, in which an abscess and death followed the use of a proper-sized aspirator needle, and the complication was attributed to the failure to keep up aspiration while the needle was being withdrawn. Dr. Weir had also since heard of a case in which death resulted in a similar manner, and yet this operation had been justly regarded as a safe one, it having been done in one case twice a day for a month.

CYSTS OF THE CHEEK.

Dr. Post presented a tumor removed from the middle of the cheek of a woman, thirty or thirty-five years of age. Externally there was a translucent swelling projecting from the skin which evidently contained fluid. Beneath it a hard mass could be felt, and after the tumor was removed it was found that the hard mass was a second cyst attached to the one that projected externally.

CARCINOMA OF THE BREAST.

Dr. Post also presented a mammary gland removed from a woman fifty-three years of age. The special point of interest was the extreme degree of retraction of the nipple. Although the breast was firm, it did not have any hard nodules so commonly felt in ordinary cases of scirrhus. One pathologist had recommended that an operation should be avoided because of the insufficiency of the evidence that the gland was the seat of malignant disease. Dr. Post, however, regarded the general induration and the deep retraction of the nipple sufficient to justify amputation and accordingly performed the operation, believing it to be necessary to remove the breast as early as possible if it was the seat of malignant disease.

The following was the report of a microscopical examination made by Dr. T. E. Satterthwaite: "The nipple was unusually retracted, and at its base, within the substance of the gland, some softening had taken place. From this point as a centre and radiating outward toward the periphery of the mamma were glistening cords, of a pearly transparent appearance, firm to the touch and creaking under the knife. From these large cords smaller ones were given off, which penetrated the gland-tissue and its enveloping fat, giving every portion of the breast a much firmer consistency than usual. The microscopical appearances were in no way different from those commonly observed in 'scirrhous carcinoma.' The disease, however, had commenced in the larger milk-ducts in all probability, and in this way the very great retraction of the nipple is accounted for. The epithelial corpuscles were not cylindrical, but more or less spherical."

The Society then adjourned.

Carrying out the Medical Law in California.—The State Board of Examiners at their August and September meetings reported the licensing of ten medical men under the law. They also reported the arrest of eight men who had been practising without a license. One of these ran an "anatomical museum." Three fines of $50 had been collected.

Correspondence.

THE SYMPTOMS OF INTUSSUSCEPTION.

To the Editor of The Medical Record.

Sir—In the last number of the Record (vol. xviii., No. 20, p. 552) the following passage occurs in the report of the proceedings of the Pathological Society, in a discussion upon the diagnosis of intussusception:

"A case of invagination had occurred a few weeks before the meeting, in which the whole question of diagnosis turned upon the existence of a tumor. An accomplished surgeon was called in, but because no tumor could be discovered he declined to operate. An autopsy of the child, a few days afterward, showed well-marked intussusception."

I desire to call attention to two serious errors in this statement. The gentleman making the remarks had evidently been misinformed. I did not decline to operate "*because* no tumor could be discovered," nor did the *whole* question of diagnosis turn upon the existence of a tumor. In truth, the *absence of a tumor* was, in my judgment, but an insignificant factor in the problem.

In cases of intussusception it is well known that the three prominent symptoms are vomiting, straining at stool, with the discharge of nothing but blood and mucus, and an abdominal tumor. With all three symptoms present a diagnosis is most easily made. With all of them *absent*, I am of opinion that a diagnosis is beyond human ken; and such was the condition of the little patient whom I saw, with another physician, who had himself grave doubts as to the nature of the trouble.

I declined to operate *because* there had been neither vomiting nor bloody stools since the first day of attack (two days previous), and *because the symptoms, since then and at the time of my visit, did not point sufficiently to obstruction to warrant laparotomy.* In this opinion the attending physician entirely coincided.

Had there been evidence of obstruction at the time of my visit I should have unhesitatingly advised and performed the operation, regardless of the question of the existence of a tumor.

As no surgeon would be justified in operating for stone unless he had himself recognized its existence, so should he decline to operate for intestinal obstruction, unless he be morally certain that such obstruction exists.

One other correction I would make in the doctor's remarks; namely, I am not "an accomplished surgeon."

S. Whitall, M.D.

NON-RESTRAINT OF INSANE AND DEATH-RATE.

To the Editor of The Medical Record.

Sir—In the number of the Record dated October 30, 1880, one of your correspondents, named "Querist," raises the question as to the influence of non-restraint or restraint on the death-rate. While acknowledging the value and pertinency of Querist's criticism, and believing that mechanical restraint is indicated in certain cases, still I must call "Querist's" attention to the fact that he has totally omitted to take into account what mathematicians call the "personal element of his equation." This, as Storer* has pointed out, is by no means inconsiderable, since, as one superintendent informed him, the death-rate could be legitimately altered fifty per cent. by simply calling the attention of the friends of dying patients to the fact that it would be better for them to die at home in the bosom of their families. An examination of the death-rate of any badly managed county asylum will show that it is less than that of many well-managed state asylums, simply for the reasons above given. These personal factors do not enter into the English statistics, because of the strict government supervision. Trusting this will satisfy Querist as to the reason for the lesser American death-rate,

I remain yours, etc.,
James G. Kiernan, M.D.

141 Second Avenue.

INTERMITTENT HEPATIC COLIC FROM GALL-STONES.

To the Editor of The Medical Record.

Dear Sir—I would like to add to the notes of the case reported under the above title on page 552 of the Medical Record, that the stools are always clay-colored, excepting when ox-bile was administered *per orem* (even then the change in color was not very marked). There was no perceptible change in their color after an attack of colic. Previous to the commencement of a paroxysm the distended gall-bladder could sometimes be easily distinguished below the margins of the ribs. The frequency of the paroxysms was decidedly increased by the use of Boldo, and the distress attending them was somewhat relieved by draughts of hot water rendered alkaline with bicarbonate of soda. The administration of ox-bile in doses of ten to fifteen grains thrice daily had no very decided influence upon nutrition.

The effect of boldo upon this case was really the most notable circumstance connected with it.

Yours very respectfully,
F. A. Castle, M.D.

New York, November 13, 1880.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from November 7, 1880, *to November* 13, 1880.

King, Wm. S., Col. and Surgeon. His leave of absence still further extended six months on account of sickness. S. O. 240, A. G. O., November 9, 1880.

Worthington, J. C., Capt. and Asst. Surgeon. Granted leave of absence for six months. S. O. 241, A. G. O., November 10, 1880.

Wood, M. W., Capt. and Asst. Surgeon. Assigned to duty at Fort Brady, Michigan. S. O. 201, Department of the East, November 12, 1880.

Satterlee, Richard S., Lieut.-Colonel and Brevet Brigadier-General, Chief Medical Purveyor, U. S. Army—retired. Died at New York city, November 10, 1880.

---

* Insanity in Women.

Medical Items and News.

Contagious Diseases — Weekly Statement. — Comparative statement of cases of contagious diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending November 13, 1880.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro spinal Meningitis.	Measles.	Diphtheria.	Small-pox.	Yellow Fever.
Nov. 6, 1880.	0	18	100	2	13	83	1	0
Nov. 13, 1880.	0	21	102	3	11	77	3	0

Among the Delegates to the recent Episcopal Convention in this city there were ten physicians.

Lucretia Mott, whose death has been recently announced, was one of the founders of the Woman's Medical College of Philadelphia, the first college of the kind in the country. She was an earnest advocate for the medical education of women. She also wrote a book entitled "Advice to Medical Students."

Treatment of Voluntary Fasting.—A correspondent of the *British Medical Journal* writes that the use of a little chloroform in patients who refuse to eat or drink, will often dispel their obstinacy.

A Malaria stricken Town.—At Franklin Furnace, Sussex County, N. J., malarial diseases are so numerous that there are not enough well people in the village to nurse the sick. Most of the male population is idle, and the place has the appearance of a hospital. This was the state of affairs reported the second week of October.

Early Rising.—The *Lancet*, in discussing the subject of sleep gives the advice, as good as it is old, that people go to bed early and get up early. This is all very well, but it also recommends that a person jump out of bed as soon as he wakes, without any dallying. This is not so thoroughly commendable a practice. There are excellent reasons against a person's suddenly forcing his system from the oblivion of sleep into a full physical activity. Will not the *Louisville Medical News*, which has been defending candy and corsets so judiciously, say a word in favor of "a little more folding of the hands."

Quarterly Report of the National Board of Health for the quarter ending October 1, 1880. The Board announces that since its last report the following work has been accomplished: A report upon the size of sewers, by G. E. Waring, has been finished. A sanitary survey of the city of Baltimore has been made. The final report of Dr. S. E. Chaillé, regarding his work in connection with the Havana Yellow Fever Commission, is completed and awaits an appropriation from Congress for its printing. Mr. R. Pumpelly has been continuing his work of investigating the relations of different soils to drainage. Dr. G. M. Sternberg is now studying malarial germs, with particular reference to the alleged discoveries of Tomassi and others in this direction. Dr. C. Smart's investigations into the adulterations of food are so far advanced as to furnish proof that such adulterations do exist.

The Board has appropriated $500, to pay the expenses of a person, who is to proceed to London and confer with the Committee of the Royal College of Physicians engaged in the revision of the standard nomenclature of diseases.

During the past summer the Board has had its inspectors travelling through the south and investigating the sanitary condition of places liable to epidemics.

In the matter of maritime quarantine, there have been established three stations, respectively at Hampton Roads, Sapelo Sound, and Ship Island, for the detention and disinfection of vessels from infected foreign ports. These stations have given general satisfaction, except in the case of Ship Island. Here there has been some disagreement between the National and the New Orleans Health Boards. Some further disagreement occurred also between the National Board and the State Board of Health of Louisiana. It was in relation to an epidemic of a suspicious character that occurred at Point à la Hache, near the Mississippi quarantine. The disease was pronounced to be yellow fever by Drs. G. M. Sternberg, Bemiss, and Mitchell; it was considered to be a malarial fever by Dr. G. P. Davidson, of the State Board, and Dr. J. D. Bruns.

The expenses of the National Board for the past quarter were $49,921.53.

The U. S. Marine Hospital Ambulance-Steamer, J. M. Woodworth, boarded the bark "Dunrobin," which was flying a distress signal in our harbor a short time ago, quelled an incipient mutiny, captured a boarding-house runner's boat with seven deserting seamen, and took them back to the bark.

Treatment of Fetid Perspiration of the Feet.—Dr. Charles Ambrook, of Boulder, Col., writes: "As a recipe for 'fetid perspiration of the feet' seems to be in order, and as I do not remember seeing mentioned one that never failed in my hands, I herewith send it: a one per cent. watery solution of permanganate of potassa. Bathe the feet in it night and morning, oftener if necessary, even to every hour, letting the feet dry after each bath, without wiping. A stronger solution may at times be necessary, generally a weaker one will answer. The stronger the solution the greater the discoloration of the feet, but, as it is temporary, patients prefer it to the fetid moisture."

New Jersey Sanitary Association.—The sixth annual meeting of this association will be held in the city of Elizabeth, Tuesday and Wednesday, November 30th and December 1st, at Y. M. C. A. Rooms, Library Hall. The subjects to be discussed at this meeting are: Inspection of Buildings; Subsoil Drainage in Cities and Towns; Examination of Wells, and Control of their Use in Cities; Diseases of Animals in their Relations to Human Diseases; Drainage for Health, and the Power to Condemn Lands for this purpose.

A "Row" in the French Academy of Medicine.—It will be remembered that M. Pasteur has been making investigations into the pathology of chicken-cholera, and that he has announced the discovery of the "vaccine" matter which will prevent the disease. The method of obtaining this "vaccine," however, he has so far declined to disclose. The subject came up for discussion at the French Academy of Medicine a short time ago, and M. Jules Guérin sharply attacked Pasteur for his announcing a discovery and refusing to tell the secret of it. M. Pasteur retorted very hotly. His most offensive phrase was: "When in the name of clinical principles a man has proposed to aspire pus to the surface of wounds by means of an india-rubber cap, some tubes, and a pneumatic pump, he is capable of anything (*on est capable de toutes les audaces*), and finds the careful and correct experimenter, who will not announce his method to the world before being able to demonstrate it, singularly simple. This is a question of scientific honor. I shall not risk compromising mine by too hasty publication, for the satisfaction of gratifying the indiscreet and unhealthy curiosity of M. Guérin." To this M. Guérin essayed to reply, but was prevented by a motion to adjourn. The discussion, however, was continued in a warm and informal style after adjournment, and it culminated in what may be called a "row." M. Guérin sent in his resignation, and both parties began to make arrangements for a duel. Peace was finally restored, however, and an amicable letter has been sent by M. Pasteur to M. Guérin.

Treatment of the Insane in Massachusetts.—At a recent meeting of the Norfolk District Medical Society, the subject of the management of the insane was discussed. At the conclusion the Society adopted the following resolution: *Resolved*, That in the opinion of this District Society the present condition of the treatment of the insane, prior to their legal commitment to an insane asylum, deserves a very searching investigation, and the Society would report the subject as worthy the consideration of the Massachusetts Medical Society, either in the corporate capacity or by some competent committee to be appointed by its council.—*Bost. Med. and Surg. Journal.*

The New Health Regulations—Quarterly Meeting of the State Board of Health.—This meeting was held at Albany, November 10th, there being a full attendance of the members. The most important action taken was the adoption of a series of sanitary orders, resolutions, and ordinances for local boards of health.

These regulations are substantially as follows: Everything dangerous to human life or health is deemed a nuisance, and must be removed under penalty.

The particular nuisances are then enumerated: No privy vault is to be allowed within fifty feet of a well or spring. No offal or dead animals or refuse to be thrown in the streets, and all decaying vegetable or putrid matter to be removed from cellars on or before May 1st, with a penalty of twenty-five dollars for violation. No tanner, refiner, or manufacturer of gas, starch, leather, chemicals, or fertilizers to throw refuse in any natural stream of water. No impure fish, flesh, fowl, or vegetable, or anything for human food, be allowed within the city or village limits. The penalty for a violation is twenty-five dollars, in addition to a penalty for misdemeanor. Householders in whose dwellings a case of cholera, yellow fever, typhus or typhoid fever, scarlet fever, diphtheria, or small-pox is, shall give notice to the local board of health, and, until instructions are received, shall not permit any clothing or other property to be removed; physicians and attendants also to report to such board, and avoid exposure to the public of any garments or clothing about their own persons; that such occupants refrain from leaving their premises or changing their residence until all danger to the public health shall be over; that there shall not be a public or church funeral of any person who has died of scarlet fever, Asiatic cholera, small-pox, diphtheria, or yellow fever, and the family is required to limit the attendance and prevent needless assembling in the apartments where such dead person may lie.

Other regulations are promulgated regarding the offensive odors from manufacturing establishments, slaughter-houses, sanitary inspection of buildings, contagious diseases among animals, the sale of impure milk, and the registration of vital statistics. Proper rules are laid down in regard to all these points.

Resolutions urging the importance of vaccination were passed, of which the following is the first section:

Resolved, That this board would urge upon the medical profession in every part of the state the importance of a thorough prevention of small-pox by proper vaccination, and would appeal to physicians to influence families and others under their professional care to the prompt and faithful compliance with this important duty.

A resolution was adopted that a committee of three, of which the Attorney-General shall be chairman, be named by the President, upon the necessary further legislation deemed proper, for the better protection of life and health of the state. The Chair appointed Erastus Brooks and Charles F. Chandler. Erastus Brooks and Dr. Harris were appointed to attend the annual meeting of the American Public Health Association, to be held in New Orleans, December 7th. The board then adjourned to meet in New York on November 17th.

Fifty-Cent Doctors.—The practice of underbidding, among even regular physicians, is known to be prevalent in some parts of this city. A number of such cases have been called to our attention. One of these, sufficiently illustrative, is that of a man in very good circumstances, who had been accustomed to employ an up-town physician when he or any of his family was sick. For office visits he paid a dollar. Being of a thrifty turn of mind, however, he determined to do better, if possible, and, after a little inquiry, he found a down-town doctor who would charge him only fifty cents, including the medicines; so he made the change.

It is currently reported that there are a good many physicians who will barter their valuable experience for even half the above sum. It is not a very uncommon practice for persons who are aware of the elasticity of medical charges to go from one physician to another in order to find out who will treat them or operate upon them at the cheapest rate.

We make no special protest against charging small fees when the patient is poor, though it would certainly add more to the dignity of the profession if doctors would either charge respectable fees or make the case a charitable one. But the system of covert underbidding, the practice of quietly giving out notice that "fees at this office are only fifty cents" is unprofessional and degrading. It is the spirit of the tradesman, but made a thousand times worse, because the physician assumes to be moved by some other considerations besides those of profit and loss.

A Novel Treatment for Watermelon Seeds impacted in the Rectum.—Dr. James Oliver, of Athol, Mass., writes: "I have seen in the Record several cases reported of watermelon seeds impacted in the rectum. One would gather from these that it is of unusual occurrence. I passed several years among the Sea Islands of South Carolina and found it a very common trouble among the negroes during the watermelon season. They take the handle of a common tablespoon and clean each other out when the impaction takes place, rarely calling a physician.

"The operation subjects the negro to a good deal of chaffing, as his fellow negroes accuse him of eating his melons like a hog, seeds and all. So when a negro is 'dug out,' as they call it, he is shy for a time, as he becomes the subject of ridicule."

A Cheap Hypodermic Syringe.—Dr. John M. White, of Pleasant Ridge, Ala., writes: "A simple and cheap hypodermic syringe can be made by attaching a hypodermic needle to a rubber bulb. If it is necessary for hypodermic syringes to be graduated the above can be made in different sizes; or, if not, the injection can be measured in a minim measure. The advantages of this syringe are simplicity, cheapness, and durability."

The National Association for the Protection of the Insane and the Prevention of Insanity held a business meeting on the afternoon of November 11th, at which it was voted to appoint a committee to co-operate, if possible, with the senate committe, which is now investigating the state asylums.

In the evening a reception was held in a parlor of the Fifth Avenue Hotel, Dr. H. B. Wilbur, of Syracuse, presiding. In his opening remarks he said that, at a moderate estimate, there are 50,000 insane in the United States. The state of New York, having 5,000,000 of population, has 10,500. Half of the 50,000 are in state hospitals or asylums; about 2,000 are in incorporated or private institutions; about 7,000 are in city or county asylums, and about 16,000 are in county poor-houses or in the custody of friends.

Following the president, the Rev. Arther Brooks spoke upon the subject of the evils of the interference of politics with the administration of charities and correction. The arguments for separating politics from charities were presented with much force and eloquence. To administer charities and correction, he said, is the hardest kind of work, requiring the wisest and best training, and politics is not the school n which to fit men for this. Politics are more likely to make men insane than to cure insanity.

Dr. G. M. Beard gave a series of conclusions which he had arrived at from a visit to several asylums in Great Britain and Germany. The first was, that in the management of the insane Great Britain is ahead of all the world, with Germany close behind. In Scotland the insane are better treated than anywhere else. Second, some method of central governmental supervision of the insane is practised in those counries and France. The United States is alone of the hree nations in compelling its insane to depend on superintendents and local trustees. Third, in the best asylums mechanical restraints have been reduced o a small percentage, and the patients are employed at some kind of labor. The extent to which the insane are employed was almost incredible. He saw hem not only cooking and washing, and engaged in agriculture, but even in various trades. Fourth, paients in the best asylums are treated like children, with a watched and guarded liberty. Fifth, the best asylums are not enormous or imposing buildings, but series of moderate-sized cottages. It is believed and asserted that this spreading of the insane over arge areas gives immense advantages toward restoraion. Sixth, the methods which have proved most atisfactory in Europe can and will be introduced nto America, despite the present existent difficulies. The chief of these is the nature of our poitical system.

Dr. E. C. Seguin read extracts from the letter of an eminent German specialist, upon American insane asylums. The letter was published in the *Archives of Medicine* and has been already noticed in the Record. Its reading excited marked attention. Dr. W. J. Morton gave a very interesting description of his visit during the past summer to the insane colony at Gheel, and to another somewhat similar institution at Clairmont, France. He spoke favorably of what he saw at Gheel, but was most impressed by the institution at Clairmont, which he considered a remarkable one in every respect. It was composed of two farms of 1,500 acres each, with a central infirmary. Each farm was complete, having its own flour-mill, blacksmith's shop, etc., and live stock. The men are employed in agriculture, etc., and the women in laundry work. Even the engineer and fireman of the laundry were lunatic women. All were happy, laughing, joking, and discussing various subjects. No attendants were visible. The institution has 900 patients of all phases of insanity, and all of the lower classes, but not one was under any form of restraint.

The meeting concluded with some brief remarks from Mrs. Erminia Smith and the president. The attendance was large and much interest was aroused in the objects of the Association.

The Second Edition of Dr. G. M. Beard's work on Neurasthenia is to be translated into German by Dr. Neisser, of Breslau.

Small-pox has appeared in Brooklyn; diphtheria has also been quite prevalent there.

The Influence of Strong Winds on Diphtheria.—Dr. John Binnie, of Poynette, Wisconsin, calls attention to the influence of cold winds upon the increase of diphtheria. In his region the north and northwest winds, with a clear sky, have this particular effect.

Dr. Tanner and the Mean Weight of Man.—In relation to the now historic performances of Dr. Tanner in this city, the *Union médicale* gives some data from M. de Parrille regarding the mean weight of man. This weight is seventy kilos (a kilo is a little less than two pounds), which is constituted as follows: Muscles, 31 kilos; skeleton, 12.40; skin, 5; fat, 12; brain, 1.40; thoracic viscera, 1.20; abdominal viscera, 4; blood, 3. The total weight of the liquids is 40 kilos, and of the solids 30 kilos. In twenty-four hours the body loses 2 kilos, 700 grammes of water, 250 grammes of carbon, 25 grammes of nitrogen, and 25 grammes of mineral substances. In order that the receipts may balance the expenditures, there are required 500 grammes of dry aliment, 650 grammes of oxygen, and 2,300 grammes of water. An individual who ceases eating can only be nourished by his own tissues and his own fat; and supposing he be very fat, he has at his disposal about fifteen kilos, after which the human machine must become wasted and the subject dies. It results from the above figures that the daily physiological loss in carbon and nitrogen is about 300 grammes. In 15 kilos we have fifty times 300 grammes—*i.e.*, absolute exhaustion will not take place before fifty days, if we admit that 15 kilos have to be expended, which is a somewhat high figure. Dr. Tanner thus nearly approached the theoretical limit. It is said that he lost thirty-two pounds during his fast, which is above fifteen kilos. If we add to this some kilos due to excess of water, we find the real *déperdition* agreeing pretty nearly with the theoretical *déperdition.*

Thus the experiment was rigorously possible, supposing the constitution of the subject admitted of it.

Pleasant for the Children.—A reviewer in the *Louisville Medical News* discourses as follows regarding certain opinions of Dr. Rumbold: "Candies, cakes, and pastries should be prohibited, says Dr. Rumbold, and in this advice he is sustained by popular prejudice and the common voice of the profession. On this point experience has convinced us that Dr. Rumbold is utterly, totally wrong. The natural appetite is seldom a false guide in diet, either in sick adults or children. . . . The craving for candies, cakes, and pastries, as well as for fruits, is natural, physiological, and should be gratified. If such appetite is excessive and excludes totally meat diet, then the ferruginous and bitter tonics, and sun and air, and not deprivation of one class of food and compulsion of the other, are the proper measures for the welfare of the patients."

Burning of an Insane Asylum.—The Insane Asylum at St. Peter, Minn., containing 650 patients, caught fire from some unknown cause during the night of November 15th. The loss of life is stated at from three to fifty, but no reliable reports have been received up to the time of going to press. The damage to the building amounts to $200,000, the north wing in which the fire originated being destroyed. The structure occupied ten years in building, and was completed three years ago at a cost of $500,000.

Music as a Therapeutic Agent.—The case quoted by *The British Medical Journal*, in which Dr. Francis, of this city, saved the life of an apparently moribund lady by playing to her on the banjo, has called out further communications on the subject of the therapeutic value of music. Dr. G. Herbert Lilley writes that he is a believer in the efficacy of this agent, and that he published a pamphlet early this year entitled "The Therapeutics of Music." He was not the first to write on this subject, however. In 1803 Dr. Louis Roger, of Montpelier, published a treatise entitled, "Traité des effets de la musique sur le corps humain;" and in 1874, Dr. Chomet wrote on "Effets et influence de la musique sur la santé et sur la maladie."

Should music after all become more popular than pills in the treatment of disease, the physicians of this city at least would no doubt be fully prepared for the change. Very many of the medical men of the city have fine musical accomplishments.

A Homœopathic College in England.—Efforts are being made among the English homœopaths to start a college of their own. Owing to the smallness of their numbers, however, and private dissensions, the effort is not likely to succeed.

Fuchsine in the Treatment of Bright's Disease has been adopted in some of the hospitals of Italy. It is given in doses of grs. viij. to ʒ ss. t.i.d. The effect is to color the whole digestive tract, deepen the color of the blood and of the urine. The albumen is then reduced in amount, and the symptoms generally improve. In cases where it does not avail, it is observed that there is no coloration by it of the urine. In this case some obscure alteration in the action of the kidney must be admitted.—*Cor. Chicago Med. Journ. and Exam.*

General Practitioners and Specialists.—Dr. George Johnson, at the introductory address of the King's College Medical School, said some pretty severe things regarding the abuses which had grown about specialism. After referring to the indiscriminating way in which the public often looks at the matter, he related the following anecdote of Dr. Latham: "Dr. Latham, as you are aware, was a very eminent, learned, and accomplished physician of St. Bartholomew's Hospital, but he had published more on the diseases of the heart and lungs than on any other subject. A patient of his, who had recently recovered from some pulmonary affection, one day said to him: 'I feel that as regards my lungs, I am quite well, and now I think of going to consult Dr. Watson about my general health.' To which Dr. Latham replied: 'Yes, I see—in your estimation Dr. Watson is an architect, and me, I suppose, you look upon as a bell hanger.'" Dr. Johnson advised the students to be architects, learning at the same time how to hang a bell.

The Taste of Chloral is very disagreeable to many. It is said to be disguised by administering it in syrup of gooseberries, with the addition of a drop of chloroform to each grain of chloral.

Hydatids in the Bladder.—Dr. J. A. McKinnon, of Selma, Alabama, writes: "I reported a case in the *American Medical Weekly*, Louisville, Ky., "in 1874 or 1875. The purport of it, according to my recollection, was a case, when I first saw it, that ha every indication of cystitis with great thickening o the walls of the bladder. Frequent micturition caused my patient to exclude herself from society for two years before a correct diagnosis of her case was formed. She was becoming prostrated from her constant dysuria, and, in order to give her quietude, I attempted to introduce a Syme's catheter to be retained during the night, but, meeting wit an obstruction in the bladder and by manipulation with catheter finding that she was insensible a to the point of the instrument, I concluded that hydatid formation was present, and designed at onc to have it expelled if possible. I would say her one of the strongest arguments in my own mind, a the time, of hydatid formation was, when force wa used to push the instrument farther, a small amoun of fluid escaped and no blood.

I injected into the bladder two drachms of liq sodæ chlor. (French preparation). In about an hou violent spasms of the bladder occurred, the urethr dilated, and there was expelled into the vessel abou a pint of hydatids. The shape and attachment o these resembled the cactus; the sacs were transparent and well defined. There was but slight hemorrhage. This I attributed to the forcible distentio of the urethra. It is now over five years since thei expulsion, and up to this day my patient has had n more inconvenience with her bladder.

Fortunately my case was a female, and she is well this might not have been if it had been one of ou own sex.

Hospital Sunday in Philadelphia.—A meeting professional and business men was recently held i Philadelphia for the purpose of inaugurating th observance of a "hospital Sunday" in that city. committee was appointed to arrange the matter, an it is probable that eventually a permanent association will be organized.

The Medical Library Journal is the title of a other new medical journal published monthly i Boston. It appears without a salutatory, and th name of its editor is not given. It is to be devote chiefly to the reviewing of books and literary notice The contents of the first number are excellent.

Original Lectures.

ON THE

PHYSIOLOGICAL ANTAGONISM BETWEEN MEDICINES, AND BETWEEN REMEDIES AND DISEASES.*

By ROBERTS BARTHOLOW, M.D.,

PROFESSOR OF MATERIA MEDICA AND THERAPEUTICS IN THE JEFFERSON MEDICAL COLLEGE, PHILADELPHIA.

(Special Report for The Medical Record.)

Lecture II.

THE ANTAGONISM BETWEEN OPIUM AND BELLADONNA, CONTINUED.

Mr. President and Gentlemen—My first lecture was occupied chiefly with a historical review of the doctrine of contraries, from the time of the aphorisms of Hippocrates to the time of Bichat. I then traced the modern revival of the subject, in the doctrine of antagonisms, from the indignant protest of Bichat against the absurdities and inconsistencies which had so long prevailed in the world of therapeutics, down to the latest investigations and discoveries which had been made in this field. I showed that Magendie was the first physiological experimenter, and that one of the most brilliant results of his studies was the discovery of strychnia as a tetanizer against paralysis—the first application of a remedy as an antagonist to a diseased state. (In this way Dr. Bartholow continued until he had given a complete and detailed outline of the previous lecture; when he went on to speak as follows in regard to the antagonism between opium and belladonna:)

A review of the fifteen fatal cases in which the antagonistic drug was the principal agent employed in the treatment diminishes very greatly their importance as evidence against the existence of such an antagonism. From a consideration of these cases we may safely conclude that where, in any instance, the use of the antagonist fails to counteract the effects of a poisonous dose of its opposite, either (1) the toxic dose has been excessive, (2) that it acted so long in the system that the tissues could no longer respond to the action of the antagonistic agent, or, (3) that the antagonistic action was defeated by the failure of some vital organ.

In eleven of the cases referred to the treatment was inefficient; in six, but a single injection of the antagonistic agent was given, and in all the proper quantity required was not stated. In two of the fifteen, on the other hand, the antagonist was given in excess, and there can be no doubt that death was really due to the preponderating influence of the latter. In six the patients were already in a pathological condition; so that in these the doctrine is not in the slightest degree invalidated. If, therefore, in the series of fifteen cases, all the sources of fallacy are removed, the amount of evidence remaining is so trivial as to be scarcely worthy of consideration, and so preponderating are the examples of success, that it must be admitted that there is a high degree of certainty in the antagonistic application of opium and belladonna.

The next point to engage our attention is the necessity of determining that the amount of poison taken in the successful cases was sufficient to constitute a lethal dose. This is a very difficult matter, for comparatively small doses of opium and laudanum have sometimes proved fatal, according to Taylor and other reliable authorities; and, on the other hand, no less than eight ounces of laudanum have been taken without injury. In one instance a drachm of the extract of belladonna did not prove fatal, while in another two grains of atropia destroyed life. Harley has collected a number of cases in which the ordinary lethal doses did not prove fatal, notwithstanding the fact that no antagonist or other efficient means of treatment had been employed. Consequently it becomes necessary to look into the one hundred and six successful cases, and see whether in all a really lethal dose was taken. Still, the antagonism may be admitted to exist if well-marked symptoms caused by one are removed by the other. Among them was one case where thirty grains of crude opium were taken, another in which an ounce and a half of laudanum, another in which from twelve to fifteen grains of morphia, another in which five grains of morphia, another in which six grains of morphia, and another in which a teaspoonful of belladonna liniment, were taken. In all but two we find that lethal doses were undoubtedly taken, and hence in this series of cases are fulfilled the necessary conditions for determining the antagonism.

A source of fallacy in estimating the validity of the antagonism in these cases is the fact that in the greater number of them various approved agents, such as emetics, the stomach-pump, faradization, ambulation, flagellation, etc., were made use of in addition to the antagonist. The state of the pupil, the phenomena of respiration, and the action of the heart, however, showed conclusively the action of the antagonist in them all. Very often in such cases the protracted efforts at resuscitation are injurious. Dr. Johnson, of Shanghai, China, quoted in my last lecture, says that when the system is fairly under the influence of atropia, with the respiration tranquil, however slow it may be, it is only injuring the patient to resort to artificial respiration. The violent measures which are frequently resorted to, such as ambulation and flagellation, sometimes quite exhaust the remaining strength of the patient, and, in certain instances, there can be little doubt that they have really been the cause of death.

Let us now examine the evidence in opposition, based on experiments upon animals. It is unfortunate that the results of the first of these experiments, by Brown-Séquard, Bois, Harley, and others, were vitiated by the fact that the observers did not first determine the exact lethal doses of the drugs. In 1866 Erlemeyer published a series of researches in which for the first time the nature of the antagonism between morphia and atropia was determined in animals. This he conclusively demonstrated to exist in their action upon the brain, pupil, heart, and respiration, and he also showed that the two agents were much better borne by the system when given in combination than separately. Somewhat the same results were obtained by Harley, who thus formulates his observations on dogs: "1. Belladonna, when administered simultaneously with opium, more or less completely prevents nausea and vomiting, and when given previously, entirely prevents these effects. 2. Whether given previously, simultaneously, or subsequently, atropia completely counteracts the respiratory restraint on the free action of the heart, which is so prominent an effect of the operation of opium. We can wish," he goes on to say, "for no more perfect an illustration of the beneficial influence of a medicine under suitable conditions than that afforded by the simple and direct action of atropia in relieving the impending syncope which often persists for many hours after a dose of opium. . . . Whilst the spinal effects of opium on the muscles of organic life are thus counteracted by the stimulant action of atropia on the sympathetic, the cerebral and anæsthetic effects are intensified and prolonged by belladonna, and hypnosis is converted into narcosis."

---

* Cartwright Lectures of the Alumni Association of the College of Physicians and Surgeons, New York.

In 1870 Koning published some results of experiments on animals which led him to decide adversely to the existence of the antagonism between opium and belladonna, notwithstanding that he noted the opposing influence of the drugs upon the heart, respiration, and pupil. In 1873 Fröhlich experimented upon cats and frogs, and although he observed decided points of opposition between the agents, he found that the antagonism was not sufficient to prevent death when lethal doses were given. In 1874 the report of the committee of the British Medical Association, of which Prof. J. Hughes Bennett was chairman, appeared. The committee took extraordinary pains to determine whether or not the supposed antagonism really existed, and the important conclusions at which they arrived after their experiments, which were mainly conducted upon rabbits, were as follows:

"*First.*—Sulphate of atropia is physiologically antagonistic to meconate of morphia within a limited area.

"*Second.*—Meconate of morphia does not act beneficially after a large dose of sulphate of atropia, for in these cases the tendency to death is greater than if a large dose of either substance had been given alone.

"*Third.*—Meconate of morphia is not specifically antagonistic to the action of sulphate of atropia on the vaso-inhibitory nerves of the heart.

"*Fourth.*—The beneficial effect of sulphate of atropia after the administration of large doses of meconate of morphia is probably due to the action sulphate of atropia exercises on the blood-vessels. . . . It may also assist up to a certain point, not precisely fixed in these experiments, by stimulating the action of the heart through the sympathetic, and obviating the tendency to death from deficient respiration observed after large doses of morphia."

In 1876 experiments were made by Corona on dogs and cats, from which he arrived at the conclusion that a partial, but not a therapeutical antagonism existed between opium and belladonna; for while the poisonous effects of morphia might be overcome by the administration of atropia, the reverse of this was not true. In this opinion Corona stands alone. In 1877 Dr. Hans Heubach also published the results of a series of experiments upon animals, made at Binz's laboratory, at Bonn, and his conclusion was that a limited antagonism existed between the two agents in their action upon the cardiac and respiratory organs. All the experiments on animals have been singularly uniform in their results, however the interpretation of the facts thus demonstrated by the various observers may differ; and if the lethal effects be omitted from consideration, they are certainly of great value in the elucidation of the antagonism of opium and belladonna on man, for they successfully demonstrate not only the nature of this antagonism, but the method of its production. We find, then, from these experiments also, that the two agents are antagonistic on the pupil, the respiration, and the action of the heart.

We may now proceed to the investigation of the nature of the antagonism as it exhibits itself in man; and, in the first place, it is necessary for us to form a definite conception of the physiological effects of the two agents. What is the action of each, in what respects do their effects agree, and in what do they differ? The action of each in full and lethal doses must therefore be understood. When a full dose of opium is taken, drowsiness (in some subjects persistent wakefulness is noticed) ensues, the pupils contract, the tongue and throat become dry, the appetite fails, constipation results (from diminution of secretion and impairment of muscular power in the walls of the intestines), the heart slows, the respirations become less frequent, the urine becomes scanty, and is passed with difficulty, and the skin is covered with a profuse perspiration. When a lethal dose is taken all these effects are intensified. The patient passes into stupor, and from thence gradually sinks into a state of coma, from which no kind of irritation can arouse him; the pupil contracts to a pin's point; the conjunctiva grows insensible; no reflex action can be set up by irritation of the cornea or fauces; the respirations become stertorous, and fall to six, four, or even two per minute; the pulse is weak, and may be either slow, or rapid and irregular; the skin is covered with a clammy sweat; the countenance is sunken, and may be either pale or livid; the ears become purple, and the back of the neck a bluish black from the ecchymoses which occur; the extremities grow cold, and death occurs by failure of the respiration.

When a full dose of belladonna is taken, the mouth and lips become dry, and there is difficulty of deglutition, fulness of the head, vertigo and tinnitis aurium; flying pains through the head and elsewhere ensue, and there is marked excitement, great volubility, and a busy delirium, in the hallucinations of which the individual is apt to imagine himself pursuing his ordinary avocations; the pupils are widely dilated; the heart's action is quickened, and, though there is at first increased arterial tension, this afterward diminishes to below the normal standard; the respirations are increased; the bowels are usually relaxed; there is muscular inco-ordination; the face is flushed, and frequently a scarlet efflorescence spreads over the skin, and the urine is passed with difficulty. When a lethal dose is taken the same symptoms are increased in intensity: vertigo quickly comes on; the vision becomes dim and uncertain from the extreme dilatation of the pupils; there is acute and violent delirium succeeded by coma; the pupils dilate until nothing of the iris can be seen; the mouth is utterly devoid of moisture, and the tongue lies in it shrivelled and dry as a bone; the flush of the face is succeeded by a deadly pallor; the pulse and respiration are very rapid; the temperature rises; the increased arterial tension is followed by paresis of the vessels, rendering the pulse weak and irregular, and death takes place from failure of the heart and lungs.

In man it is found that there is a distinct antagonism between the two agents in their effects upon the brain, the pupils, the stomach, the lungs, the skin, and the heart. When they are administered in proper doses together the result is a calm and apparently natural slumber, as is shown in the case reported by Dr. Legg, where the patient, a boy five years of age, swallowed a mixture of equal parts of opium liniment and belladonna liniment. The same thing was observed in a case treated by Dr. Mussey, of Cincinnati, and myself. There the patient was a boy of eight years, who swallowed by mistake an anodyne application for earache, containing two grains of morphia and a grain and a half of atropia. We found the pupils fully dilated and the face flushed, with the presence of active delirium. Afterward a state of sopor set in, as in Dr. Legg's case; but, as the respiration was full and rhythmical, and the pulse regular and strong, we determined to await the result without attempting any interference. We were both perfectly agreed as to this being the proper course under the circumstances, and the sequel perfectly justified the view we had taken of the case. Another case, in which opium and belladonna were taken together by accident, is reported by Dr. Cotter. A young lady swallowed a portion of a liniment containing twelve grains of opium and twenty-five grains of extract of belladonna. As in the other two cases, the effect of the belladonna largely preponderated at first, but afterward the stupor of opium, narcotism came on. Still later there was a return of the excitement and delirium caused by the former, and then, finally, sopor succeeded again, from which she finally awoke relieved. Such being the results of the accidental taking of the two agents conjointly, let us next inquire what the clinical facts of the case are.

Mitchell, Morehouse, and Keen conclude that "the headache and phantasms of atropia are certainly thus controlled (by morphia), as well as the partial deafness and visual defects which in high doses it occasions. On the other hand," they continue, "when morphia has been fully used, the drowsiness and stupor, which are the best tests of its power, disappear before the influence of atropia. . . . . Perhaps the most peculiar cerebral symptom of atropia is its tendency to cause phantasms and illusions. We found, under doses of one-twenty-fifth of a grain, these were common, and in some men could always be brought on. . . . . This condition was singularly subdued by morphia. Drowsiness caused by morphia was as surely lessened or destroyed by the counter-agency of atropia; and, in fact, atropia given alone and in full doses is very apt to cause a restless night to follow, so that it is assuredly in no sense a hypnotic."

Harley strongly insists on the modifying action which opium has upon the cerebral effects of atropia; yet, strangely enough, he does not regard the effects of the two upon the brain as antagonistic, but as synergetic. Yet in his observations we find the same results that were obtained by Mitchell, Morehouse, and Keen. The fact is that professional opinion is no longer divided on this point, and at the present day opium and belladonna are frequently prescribed together in order to get hypnotic effects which are not attainable by either alone.

The results of clinical experience on man have been confirmed by observations on the lower animals, so far as they are applicable; but the effects of opium and belladonna on the brains of animals can be compared with those upon the brain of man only according to the extent of development, for the human brain must necessarily be affected less severely and in a greater variety of manifestations on account of its more complex structure and higher physiological development. In this difference of development seems to lie the explanation of the fact that morphia and atropia when given together have so much greater toxic effect upon animals than on man. In regard to this Bernard says that from the physiological point of view the experimental study of the organs of sense and of the cerebral functions must be made on man necessarily, because on the one hand man is above the animals in respect to those faculties of which they are not possessed; and on the other, animals are unable to indicate the nature of those sensations of which they may become conscious. Hence my conclusion is that, as respects the brain, opium and belladonna exert opposite actions.

The result of their combined action, when the quantity of both the agents is large, is sopor, which deepens into coma. When administered simultaneously, if the effect of the belladonna preponderates, periods of excitement and delirium will alternate with relatively shorter periods of sopor; while the more opium preponderates the less excitement and delirium will there be, and the longer and more profound the sopor.

No little interest and importance attach to the condition of the pupil in cases where one of the agents is administered for the purpose of antagonizing the other. Graves, as is well known, first proposed to use this antagonism as a guide for treatment. As a general rule, opium undoubtedly contracts, and belladonna dilates the pupil; but there are occasional exceptions. It is extremely important to determine, therefore, whether this indication can or cannot be depended upon. In number fourteen of the unsuccessful cases, notwithstanding the fact that a large amount of morphia was given to counteract the effect of the belladonna which had been taken, the pupils remained dilated. In one of the successful cases of joint administration of opium and belladonna, on the contrary, where the other effects of the latter greatly preponderated, the pupil continued minutely contracted. In some instances, also, the pupil has been known to become contracted in belladonna-poisoning and dilated in opium-poisoning.

Though such cases are certainly exceptional, the fact that two of them occurred in 120 cases is sufficient to detract considerably from the value of this indication for treatment. No less than twenty cases show that the pupil may not be very much affected by the antagonist. Atropia, however, exerts the more powerful action upon the pupils, and sixteen of the twenty cases were examples of preponderating dilatation.

The next point to be examined is the antagonism of these agents upon the action of the heart. When given alone, opium undoubtedly has the effect of showing the organ, while belladonna quickens its action. Observers are not agreed, however, as to the influence of the two given simultaneously. Mitchell, Morehouse, and Keen contend that as regards the circulation they do not counteract each other, and Harley, that morphia, as in other organs, increases the effect of atropia. In my own observations I have invariably noticed that the quickening influence of atropia was appreciably diminished by morphia, and *vice versa*. This is also the conclusion which I have derived from the reported cases of poisoning; although it cannot be denied that the effect of the atropia preponderates. The experiments on animals, in addition, show that, to some extent at least, the action on the circulation of the one is antagonized by the other, and Harley's experiments on dogs certainly exhibit this in a striking manner. In the careful experiments of Heubach, too, the same result is shown. We therefore conclude that opium and belladonna have a limited antagonistic action upon the heart; but that the effect of the latter preponderates. Hence the result of the two combined is a rate of movement greater than the mean.

Undoubtedly the most important point of the antagonism between the two drugs is their opposed action upon the respiratory function, and in regard to this there is less difference of opinion than upon any other. In general terms it may be said that opium is a respiratory depressant and belladonna a respiratory stimulant. All the cases of poisoning teach this lesson. When the system is brought more and more under the influence of opium, the quantity of oxygen admitted to the blood becomes less and less, and oxidation is to a proportional extent interfered with ; so that carbonic acid narcosis is superadded to that primarily produced by the opium. Belladonna, on the other hand, counteracts these effects by increasing the number and depth of the respiratory movements, by which an increased quantity of oxygen is supplied to the blood, while excretion is facilitated. These improvements are shown by a flushed face, warm and dry skin, and greater activity of the circulation generally. Atropia proves fatal by exhausting the irritability of the heart and of the vaso-motor system, as well as of the respiratory centres. Morphia opposes these effects by diminishing the work thrown upon the heart and lungs. Nothing could be more striking than the effect of this antagonism as exhibited in many of the 120 cases of poisoning so often referred to. In a case narrated by Dr. Fothergill, the influence of the antagonist upon the respiration is most conspicuous. A woman had taken laudanum containing from twelve to seventeen grains of opium, and when first seen the respiration was almost gone, one grain of sulphate of atropia was promptly injected, and in half an hour afterward the respiration was very greatly improved. In an hour and a half it was going on steadily at thirteen per minute, and the breathing was long and deep. It is probable that in this case the amount of atropia used was almost too large, since the subsequent account shows a preponderating action of atropia. Dr. McGee, of Tennessee, also reports a very instructive case in this connection. A man forty years of age swallowed thirty grains of opium in ten or twelve ounces of whiskey, and became profoundly nacotized. In two hours one-eighth of a grain of atropia was injected, and this having no effect, in half an hour the dose was repeated. By this time the respirations were nearly suspended, and the face was livid. Under the influence of the atropia, however, the respirations now began to increase, the pulse came up to 140, the pupils became widely dilated, and consciousness was restored to such an extent that the patient could be aroused. After this he slept soundly for a number of hours ; but the pulse continuing fair and the respiration regular, full and deep, no further interferance was made in the case. I might also narrate other instances of similar character. The cases of atropia-poisoning treated by morphia are not less instructive, and these are mainly furnished by such authorities as Graefe, Schmid, Fronnmüller and other eminent ophthalmologists. In some of them the amount of atropia taken was probably not lethal ; but the antagonistic effect of the morphia was none the less marked.

If we pass from the clinical to the experimental evidence (derived from both man and animals), we are greatly surprised with the differences in the conclusions arrived at. Thus Mitchell, Morehouse, and Keen concluded, from their observations, that in this particular the supposed antagonism of opium and belladonna did not exist. In some experiments which I made personally on a medical student, I found, on the other hand, that morphia modified to a considerable extent the effects of atropia on the pulse and respiration. Harley (although he distinctly refuses to accept such an interpretation of them) educes facts which seem to prove undoubtedly the stimulating effect of atropia on the respiratory organs, in exact accordance with the evidence furnished by clinical experience. Notwithstanding such adverse opinions, it may now be regarded as settled that opium and belladonna have an antagonistic effect upon the respiratory function.

The antagonistic action of the two agents is furthermore shown in the controlling effect of atropia upon the nausea, depression, and syncope caused by morphia. This antagonism is seen when ordinary medicinal doses are given, and clinical experience justifies the wisdom of Harley's assertion that morphia should never be given alone, unless its effect on the patient is well understood, but always in combination with atropia. The explanation of the abolition of the depressing effects of the morphia thus accomplished, is found in the antagonistic effect of the two agents upon the cerebrum. But while the depression is thus prevented, this is not always the case with the nausea ; for, unfortunately, atropia also causes nausea in some individuals.

The coldness of the surface and clammy perspiration caused by morphia are relieved by atropia, and this is often a matter of considerable importance. The action of the atropia excites the vermicular contraction of the peripheral vessels, and causes more blood to be received from the heart, in consequence of which the surface grows warm and dry and the metamorphosis of tissue is accelerated. The effect of this resumption of activity at the periphery is only second in importance to the renewal of oxygenation of the blood at the lungs.

Atropia excites, to some extent, the action of the kidneys, while morphia checks the flow of urine. They both, it is true, render the emission of urine more difficult, but this is due to entirely different causes in each instance. Morphia has the effect of impairing the sensibility of the mucous membrane and weakening the action of the muscular coat of the bladder ; while atropia stimulates the sphincter to abnormal contraction.

We are now prepared to examine how a lethal dose of one of these agents counteracts the effect of a lethal dose of the other. We have seen that very rarely is this the case in animals, and this fact is, no doubt, to be explained by the difference in physiological cerebral development between man and the lower animals. Hence, we find that in animals the force of the poison is expended on a few comparatively simple organs, while in man it is diffused over much more extensive and complicated structures.

Experience has demonstrated that the quantity of poison which can actually be antagonized successfully is comparatively limited ; the amount which gets into the blood being, as a rule, very much less than that which is taken into the stomach. When the antagonism is successfully employed, what disposition is made of the poison? The fact seems to be that the two agents are simply opposed until elimination has been effected. Furthermore, the separation of the poison from the blood, and its excretion through the usual channels, is greatly promoted by the action of the antagonist in restoring and maintaining the functional activity of the organs depressed by the poison. The principal route of the excretion is through the kidneys (though the agency of the skin and intestines is also of service), and free action of the kidneys should therefore be maintained by the use of diluents. Another point of great practical importance is to draw off the urine from the bladder as fast as it accumulates. Brown-Séquard has shown that alkaloids are absorbed from the mucous membrane of the bladder; and it is probable that alkaloids contained in the urine pass back into the blood again from the bladder. The action of the bowels and skin should also receive attention.

No absolute rule can be laid down as to the dose of the antagonist to be used in any case. We must be governed in this by the effects observed upon the system. The state of the pupils is not a safe guide, because in some instances, as we have seen, they do not react normally. The true guides are the condition of the respiration and the circulation. If the pulse is full and regular, and the respiration deep and rhythmical, the state of the pupil and the depth of the narcotism are of little importance. As a rule, it is the best plan to give the antagonist in small quantity, frequently repeated, until a sufficient amount has been introduced into the system. In some actual trials I have found that one-twentieth of a grain of atropia is about equal to one grain of morphia in toxic power.

Having now finished the survey of these two agents, I submit the following conclusions:

Morphia and atropia are antagonistic in their effects on the cerebrum, and the result of the antagonism is to induce sopor; but this deepens into coma if the quantity used is larger, and hence the antagonism does not extend to lethal doses.

They are antagonistic in their action on the pupil (though this is not constant), and the effect of the atropia preponderates.

They are antagonistic in their action on the heart, but the effect of atropia is more powerful and prolonged.

They are antagonistic in their action on the respiration; morphia slowing the respiratory movements and diminishing the excretion of carbonic acid, and atropia increasing the respiratory movements and the excretion of carbonic acid.

They are antagonistic in their action on the arterial tension; opium slowing the heart and paralyzing the arterioles, and atropia counteracting these effects.

Atropia prevents, to a large extent, and often completely, the depression, coldness of the surface, cold-sweating, and cerebral nausea caused by morphia.

Morphia and atropia are antagonistic in their action on the kidneys, the one diminishing and the other increasing the urinary discharge. They differ also in their action on the bladder, the one dulling the sensibility of the mucous membrane and impairing the vigor of the muscular coat of the viscus, and the other stimulating the sphincter. They are not, therefore, antagonistic in their effect on the bladder.

In therapeutics these antagonistic actions may be utilized to secure effects which cannot be obtained by the employment of either agent alone. The whole subject affords a beautiful example of the success of the methods employed by modern pharmacological research to improve our knowledge of the action of the oldest remedies, and to increase the safety, certainty, and range of their applications to the treatment of disease.

Hippophagy is on the increase in Paris. In 1879 nearly two million pounds of horse, mule, and ass flesh were consumed.

Original Communications.

The Practical Points Afforded by the Anatomy of Some of the SURGICAL REGIONS OF THE HEAD.

By AMBROSE L. RANNEY, M.D.,

NEW YORK.

SPECIAL SURGICAL REGIONS OF THE HEAD.

There are certain *practical points* pertaining to the anatomy of the head which can be given, in detail, only by considering special regions whose anatomical construction brings them constantly to the notice of the surgeon.

It has been the custom with almost all authors upon topographical anatomy to follow some special plan as to the division of the head into regions, based either upon those landmarks which Nature has herself defined, or upon a physiological connection between the various structures. To follow in detail such a chart as Blandin recommends would increase the scope of this article beyond its proper limits, while it would conflict in many ways with the general plan of its construction. I shall therefore call attention, under this heading, only to such practical points as pertain to the temporal, orbital, nasal, and buccal regions, since other portions of the head have been quite exhaustively treated of in a previous contribution (October 15th).

TEMPORAL REGION.

In the temporal region the ear often presents numerous anomalies. The pinna may be flattened or some of its prominences may be excessively developed. The lobule may be absent or adherent to the skin, while the auditory passage may be abnormally short or narrow, and, in some cases, entirely obliterated. The ancients, deceived by the false idea that the cartilage of the ear was endowed with excessive sensibility, considered injuries to the pinna to be extremely serious; and some have even spoken of fracture of this portion, evidently mistaking an incised wound of the cartilage for such an accident.

The follicles of the external canal may, if morbidly developed, result in small encysted tumors; and inflammation of the external ear or of the auditory canal is rendered extremely painful by the close adhesion of the skin to the subjacent parts. If the external ear be removed, the hearing is markedly impaired, but is not entirely lost.

The curve of the auditory canal explains the necessity of *drawing the pinna upward* when we wish to examine it, since we thus remove the curve, which does not extend to the osseous portion of the canal. In removal of foreign bodies by instruments, it should be borne in mind that, if the instrument has only one blade, it must be carried down upon the *lower wall* of the canal, since we can thus introduce it more deeply before arriving at the membrana tympani, as this portion of the canal is the longer; but, if the instrument has two blades, one should be introduced below and the other above, as the vertical diameter of the canal is longer than the transverse, and the foreign body will be, for this reason, less pressed upon, and a greater space for the instruments will be afforded to pass inward and embrace it.

Whenever it is desired to remove an insect from the ear, the head of the patient should be inclined to one side, and the meatus filled with any mild oil, which may be retained in the ear a few minutes, simply by keeping the head in the inclined position. The oil thus occupying the tube closes the respiratory pores of the creature, and soon either kills it or causes it to seek the surface to obtain air or to escape, when it may be seized or subsequently washed out with a syringe or tepid water. Especially if inflammation exists, this latter mode should be practised, since this condition increases the sensibility of the part and renders the introduction of instruments painful.

If the foreign body should be a hard substance, and one not capable of absorbing water, then the best plan of removing it will be to wash it away by the force of a stream of water thrown in on one side of it, and made to fly outward from the resistance created to the entrance of the water by the surface of the membrana tympani.

Cases have been reported by Sabatier, Blandin, and others, of meningitis having been produced from foreign bodies which have been lodged in the external auditory canal and which have withstood all attempts at removal.

The escape of pus, which often occurs, from the auditory passage may arise from its own lining membrane, or may come from the tympanum or from the mastoid region. The auditory passage is partly membranous on its posterior wall; and this anatomical fact explains how abscesses of the mastoid or parotid regions sometimes point in this canal.

The membrana tympani is sometimes broken by loud noises, as is not infrequently the case with cannoneers; and perforation may also be produced by the pressure of accumulated and hardened wax in the external auditory canal, and sometimes by the pressure of the handle of the malleus. Artificial puncture of the membrana tympani is sometimes performed (as first suggested by Cooper in 1800) to allow the introduction of air into the cavity of the middle ear when the Eustachian tube is obliterated, or for the purpose of evacuating pus during attacks of suppurative inflammation of the tympanum.

The operation of opening the mastoid process, as a means of relief for that obstinate form of deafness produced by permanent occlusion of the Eustachian tube, was first suggested by Jasser, a Prussian surgeon, who thus hoped to establish a permanent and free entrance of air to the cavity of the middle ear by means of the mastoid cells, and who urged the facts that no anatomical difficulties existed to the operation, and that the membrana tympani was left intact, as its chief advantages. The unfortunate accident of erysipelas in the case of Just Berger (physician to the king of Denmark) brought serious criticism on Köelpin, of Copenhagen, who performed the operation upon that distinguished man, and the operation fell into disrepute.

It is a fact worthy of mention in this connection, that the mastoid cells are absent in childhood and are not fully developed until middle life.

The intense pain which is present in *suppuration of the middle ear* is produced by compression of the sensory nerve filaments, since most of the walls of that cavity are bony; hence, we find in those cases an abnormal outward protrusion of the membrana tympani, which is a symptom of great diagnostic value; and, if not surgically relieved by puncture, spontaneous perforation of the drum is liable to follow, and repair of the damage often becomes difficult.

Pages have been written on most of the aural operations, but with a tendency to confuse and embarrass, rather than to encourage the reader. Washing out the internal and external auditory tubes, with perforation of the membrana tympani, or, perhaps, the mastoid cells, really constitutes the entire portion of aural operative surgery, and all are easily executed. For this reason, the steps of catheterizing the Eustachian tube will be found appended in the description of the nasal cavity as a surgical region, while the steps necessary in the operation of opening the mastoid process can easily be ascertained by reference to any work on surgery. The dangers from the surgical relations of this process will be given in full detail later on in this article.

Wounds of the temporal region, even if not very deep, may be attended with profuse hemorrhage, especially when they are situated near the auditory passage, and the temporal artery may possibly have to be tied to arrest it.

The whole of the temporal region may be rendered prominent by tumors of the antrum which have perforated its posterior wall, passed through the zygomatic fossa, and thus encroached upon the temple.

Trephining should never be performed in this region unless the case absolutely demands it, since the thickness of the soft parts which cover the bone renders the operation a difficult one, and since the skull is extremely thin in this portion, and the brain is therefore liable to be wounded. The proximity of the *middle meningeal artery* is an additional reason why the operation should not be performed in this region, unless demanded.

In the region of the mastoid process, the *lateral fontanelle* may be abnormally large, or late in closing, and thus a hernia of the encephalon, whether of the cerebrum or cerebellum, may occur through this opening. Such cases are, however, fortunately infrequent. Wounds in the vicinity of the mastoid process may be attended with profuse hemorrhage if the cutting instrument pass either *in front* of or *behind* it, since large vascular trunks are in close relation to it, both anteriorly and posteriorly.

Caries and *necrosis* of the temporal region are frequently the result of syphilis, and *exostoses* may also be developed from the same cause. The occurrence of necrosis usually indicates that the disease has affected the pericranium, and has separated it from the bone, thus destroying its nutrition. It is a curious fact that the cranial bones are seldom reproduced after removal of the entire thickness of the skull-cap; and this seems to indicate that the dura mater does not take the place of a true periosteum, since it sends few vessels into the bone, which are chiefly nourished by the pericranium, and, for this reason, shows little if any tendency to reproduce bone-tissue.

In trephining over the mastoid process—and the same statement is applicable to other regions of the skull—the liability of injury to some of the *emissary veins*, which chiefly pass through the sutures of the skull, affords a danger of meningeal inflammation; hence all sutures should be looked upon as points of danger in trephining.

REGION OF THE NOSE.

The cavities of the nostrils are much narrower in the infant and the aged than in middle life. In the infant, this narrowness is due to imperfect development of the nasal cavity in the transverse direction; while in the aged, an excessive development of the turbinated bones tends to occlude both the superior, middle, and occasionally the inferior meatus of the nose.

The prominence on the ascending process of the superior maxillary bone may be used as a *guide* for *inserting a probe* into the lower opening of the nasal duct. In performing this operation, a probe which is properly curved is introduced along the floor of the nostril, with its point looking outward; when it has penetrated for the distance of an inch, it is generally withdrawn with the point in close contact to the outer wall of the nasal fossa, until it is arrested by the prominence above mentioned; the probe is then depressed and carried a little inward, and, by a vibratory motion, the instrument is made to penetrate the nasal duct, passing underneath a valve of mucous membrane, which partially occludes its lower orifice. Probing of the nasal duct through the nostril is now seldom resorted to on account of the valve of mucous membrane which occludes its mouth.

The cavities of the nasal fossæ communicate, in the superior meatus, with the sphenoidal sinus and the posterior ethmoidal cells; in the middle meatus, with the frontal sinus, the cavity of the antrum, and the anterior ethmoidal cells; while, in the inferior meatus, the nasal duct opens. The inferior meatus is of importance to the surgeon in the operations of plugging the posterior nares, dilating the nasal duct from below, catheterizing the Eustachian tube, and the removal of polypi or foreign bodies.

In plugging the posterior nares, should the surgeon not be able to obtain Bellocq's canula, he may readily carry a ligature through the nostril and mouth by means of a common elastic catheter, the ligature being passed through the eye of the instrument, the latter being withdrawn after the pellet is in position. After the lapse of several hours, the lint in front of the nostril should be removed by the fingers or forceps, and that from the posterior nares displaced, either by pressing it into the throat by a probe, whence it may be drawn by the thread left attached to it for this purpose, or it may be drawn out by simply employing the end of the ligature left in the mouth.

When the position of the orifice of the Eustachian tube is recollected, it will be seen that the introduction of a catheter in the mouth of that tube is a simple operation, though the verbiage in which it has often been described tends to create a belief in its being difficult.

The patient is seated with the head thrown slightly backward and firmly supported, while the surgeon takes the catheter in his right hand, and, after oiling it, introduces it into the nostril on the side to be dilated. Then, keeping its point on the floor of the nostril, and its convexity upward and inclined against the septum of the nose, he slides it backward till it reaches the soft palate, as may be readily told by the sense of touch transmitted along the instrument, or by the patient making a slight gulp or effort to swallow. At this moment the surgeon should turn the point of the catheter upward and outward by rotating it a quarter of a circle, and then, by a slight movement forward and backward, he may slip it into the tube with as much, if not more ease, than a catheter can be made to enter the bladder. When the proper position of the instrument is ensured, it will at once be known by its steadiness, and also by the sensation of the patient.

Foreign bodies in the nostril may be extracted either from the front, or pushed back into the throat, according to the proximity to one or other of these orifices. As they seldom fill up the entire front of the nose, a curette, or curved probe, or Leroy's instrument for removing fragments of calculi from the urethra, may generally be passed to one side of the article, so as to enable the operator to draw it forward. If jammed between the inferior turbinated bone and the septum, gentle pressure from above downward, by crowding it upon the floor of the nostril, will facilitate its subsequent removal, either by the instruments above named, or by a polypus-forceps, or common dressing-forceps. If, however, the foreign substance should be a piece of ribbon or something similar, which has been stuffed high up in the cavity of the nose, washing out the nostril by a stream of water with a syringe will often dislodge one end, and thus enable the operator to seize and draw it out with the forceps.

During attacks of sneezing, coughing, laughing, or fright, at the time an attempt at deglutition is being made, foreign bodies in the throat may be forcibly driven into the postero-superior part of the nares; and similar instances are recorded during attacks of vomiting, although vomited matters are usually expelled from the nose with little difficulty, in case they chance to enter.

Metallic rings have been forced into the nostril through the pharynx* during attacks of sneezing; and cherry-pits and other substances have been introduced by attacks of vomiting, and some have remained there undetected, until ozæna caused a careful examination of the nares to be made.†

Foreign bodies can also be thus forced into the Eustachian tube, as reported by Fleischmann, where a grain of barley became so lodged, and created ringing in the ears, a sensation of hair in the fauces, and interference with hearing.

It is well known that horse-flies are particularly prone to deposit their larvæ in the nasal fossæ of animals, and that, after their maturity, the animals which are hatched are often thus enabled to enter some of the air-chambers of the head. In countries where leeches abound, they are occasionally introduced into the pharynx with water drank from pools, and they thus are enabled to crawl upward and lodge themselves in the nasal fossa, where they are often detected only by the epistaxis which they create. They are extracted by *salt douches* or medicated injections, which cause them to loosen their hold and drop into the inferior meatus, where they can be reached.

The presence of any form of foreign body in the nose creates a feeling of irritation, which is indicated by an uncontrollable desire to forcibly pass air through the nose and a peculiar stinging pain and sneezing, which the patient seldom becomes deprived of, no matter how long the foreign substance be retained. By its irritation, such an accident may destroy smell, since an offensive ozæna is usually produced if the foreign body be long retained; or, by compression alone, it may occlude the nasal duct, and thus induce symptoms referable to the eye or its lachrymal apparatus, or create necrosis or caries of the bones of the nasal fossa, with the many symptoms dependent upon those conditions.

The subject of foreign bodies of the nasal fossa has much of interest which cannot be here given, and to such as seek for further information the admirable work of Poulet is recommended.‡

Swelling of the mucous membrane of the nasal cavity may partially or completely occlude its calibre and thus affect the tone of the voice, and perhaps occasion dyspnœa; while a similar swelling in the region of the lower orifice of the nasal duct may so occlude that canal as to prevent the escape of the tears through their natural channel, and thus cause them to flow over the cheek.

‡ A Treatise on Foreign Bodies in Surgery.

Abnormal tumors within the nasal fossa may be either *mucous polypi*, which are localized hypertrophies of the mucous membrane or the submucous tissue; *fibrous polypi*, which spring from the periosteum, and which are composed chiefly of bundles of fibrous tissue; *cartilaginous growths*, which spring chiefly from the septum of the nose and the frontal or ethmoidal cells; *osseous tumors, sarcomata*, and *cancer*.

The mucous type of polypus rarely, if ever, springs from the septum of the nose, but usually arises from the mucous lining of the superior or middle meatus, or from the inferior turbinated bone. In rare cases they may arise from the roof of the nasal fossa, or even from the frontal sinus,* and they may occasionally be so extensive as to hang into the pharynx.

The fibrous type of polypus, on the contrary, may grow from any part of the walls of the nasal fossa, but is most frequently attached to the basilar process at the base of the skull, and, for that reason, is usually found within the upper portion of the pharynx, behind the uvula.

REGION OF THE ORBIT.

Injuries in the vicinity of the eyebrow may be regarded as particularly liable to be followed by serious results. Death has resulted in such cases from a fracture at the base of the skull, and an accompanying amaurosis from injury to the optic nerve is frequent in such cases. Besides these two sequelæ, an *emphysematous condition of the forehead* may occur if the frontal sinus be opened, and fistulæ may remain, through which air may be forcibly blown if the nose be held.' A case is on record where, after such an accident, the patient could blow out a candle through an opening in the forehead which communicated with the frontal sinus. The supra-orbital nerve which escapes from the orbit by a foramen underneath the eyebrow may also be pressed upon by fragments of bone, and thus become the seat of a tormenting neuralgia, or, by creating reflex symptoms in other nerves which communicate with the fifth pair, may cause manifestations of a diseased condition of other parts of the head and face.†

Penetrating wounds in this region may pass above or below the globe of the eye, or they may affect the globe itself. If the eye itself be injured, it may be destroyed either as a direct result of the accident or by inflammation following it; while, if the eye be not *destroyed*, opacities of the cornea or lens may result, foreign bodies may be deposited within its chambers, the iris may be lacerated, and many other unfortunate conditions ensue which may impair to a greater or less extent the functions of the eye and lead to subsequent changes of a more or less serious character.

Wounds exterior to the globe of the eye are not as serious in their results, except in those cases where the penetrating instrument has passed deeply within the orbit and has injured (1) the orbital arch and the adjacent brain-tissue, (2) the internal or external bony walls of the orbit, (3) the important nerves and vessels situated in the sphenoidal fissure, or (4) by penetrating still more deeply the vessels of the zygomatic fossa. In this latter region, all wounds are especially serious for the following reasons: first, because such wounds necessarily presuppose that the piercing instrument, before arriving there, has passed either through the cheek, the temple, the parotid region, or the orbit; secondly, because it is almost impossible for the branches of the internal maxillary artery or its main trunk to escape injury, while Meckel's ganglion and the superior maxillary nerve may also be wounded; and thirdly, because the collateral circulation between the branches of the internal maxillary artery with the surrounding vessels is so extensive that, even if the common carotid artery be tied, the other vessels are liable to produce fatal hemorrhage.

In extirpating the eye, we must guard against plunging the instrument too deeply, in order to avoid injury to the nervous and vascular structures of that region, since, if roughly introduced, the scissors might be forced into the sphenoidal fissure, or even through some portion of the bony wall of the orbit.

In those cases where amputation of the globe of the eye is performed in preference to extirpation, the globe should be cut behind the iris, lest the contraction of that membrane prevent the escape of the vitreous humor and consequently the formation of a stump for the insertion of an artificial eye.*

Elevation of the floor of the orbit by a tumor of the antrum, or the pressure of an abnormal growth or of suppuration behind the globe of the eye, may cause a protrusion of the eyeball from its socket—a condition to which the term "exophthalmia" is applied. In case the exciting cause of such a condition be a vascular tumor, ligation of the internal carotid, or even of the primitive carotid, may be demanded.

Within the orbital region, the operations of division of certain branches of the fifth cranial nerve, for the relief of neuralgia, are performed, whose steps will be found given in detail in the general treatises on the art of surgery.

The pulley, through which the tendon of the superior oblique muscle of the eye plays, is situated at the upper and inner angle of the orbit, and in close proximity to the internal angular process of the frontal bone. Care should always be taken, in operating in the orbit, that this loop be not severed, as the action of the superior oblique muscle would thus be temporarily destroyed, and its permanent impairment rendered probable.

Abnormalities in the condition of the pupil, and deviations from the normal power of vision dependent upon anatomical defects, have previously been considered, as far as anatomy has any direct bearing upon them, in other articles of mine which treat of the second, third, fourth, and sixth cranial nerves.†

The lachrymal apparatus, which comprises the lachrymal gland, the lachrymal canals, the lachrymal sac, and the nasal duct, often creates a necessity for surgical interference in the region of the orbit. In those cases where the removal of the lachrymal gland is demanded, an incision through the upper lid is usually made, and the gland is then dissected from the surrounding parts. The loss of secretion of the gland is, in a measure, supplied by the *increased action* of the *conjunctiva*, the mucus secreted being generally sufficient to assist the action of the lid over the eyeball.

In contraction of the puncta lachrymalia, the lachrymal canals, or the nasal duct, it occasionally becomes necessary to either dilate them by a probe or to wash them out by means of a syringe. In performing either of these operations, that eyelid, in whose punctum the instrument is to be passed, must first be drawn toward the temple, since by so doing the normal curve of the lachrymal canal is straightened, and the introduction of an instrument is thus greatly facilitated. If the canal is simply to be washed out, the nozzle of the syringe (Anel's syringe is perhaps the best) is introduced into the punctum and the fluid forced into the canal with the finger, while the other punctum is compressed to prevent regurgitation. If the fluid does not pass out of the syringe as freely as the orifice should permit, withdraw the point a little, and, by again passing it forward, any duplicature of the lining membrane of the canal may, as a rule, be easily avoided.

† See New York Medical Gazette, October 16th, 23d, 30th, 1880.

In introducing a probe through the lachrymal sac and nasal duct, the instrument should be introduced in the same way as above mentioned, and with the handle of the probe parallel with the border of the lids, the point should be moved toward the inner canthus of the eye till it reaches the lachrymal sac. In some cases incision of the lachrymal canal may be required.

The handle of the instrument should now be elevated from the horizontal to nearly a perpendicular direction, when, on carrying the handle obliquely forward, the point of the probe will pass readily through the nasal duct and escape at the inferior meatus of the nostril.

The intimate nervous communication which exists between the nasal mucous membrane and the lachrymal apparatus explains why irritation of the nose is so frequently followed by an excessive flow of tears, and, for that reason, any excessive action of the lachrymal gland should always suggest to the surgeon a careful examination of the nasal cavity, in case no cause can be discovered in the region of the orbit.

The passage of the third, fourth, ophthalmic branch of the fifth, and sixth cranial nerves through the sphenoidal fissure, and of the optic nerve through its own foramen, explains why any pressure created by abnormal growths within the cavity of the orbit is so liable to be followed by symptoms dependent upon paralysis of some of these nerve-trunks, and to one familiar with the course of these nerves such symptoms often indicate the possible situation of the exciting cause.

REGION OF THE MOUTH.

Within the cavity of the mouth, the bones which help to form it, the mucous membrane which lines it, and the nerves and vessels which are distributed to it, have been considered in previous articles,* and many practical points noted which will require but casual mention here, since they can be referred to under each of these respective heads. The cheek, tongue, tonsils and soft palate, however, present points of interest both to the surgeon and medical practitioner.

In the child, the region of the cheek is particularly liable to gangrenous and ulcerative processes, while, in the adult, tumors are not infrequent in this region. Its physiological functions, in the acts of respiration, mastication, blowing, and sucking, are seriously impaired by any cause which tends to create interference with the conducting power of the facial nerve. The situation of *Steno's duct* gives to wounds of the cheek a surgical importance, since, if that duct be wounded, the escape of saliva between the edges of the wound may create a salivary fistula upon the face, and prove a source not only of disfigurement and annoyance to the patient, but one which it is often difficult for the surgeon to relieve.

The tongue may present conditions of increase in its size as the result of hypertrophy or tumors, which sometimes prevent mastication, and in rare cases may so completely fill the mouth as to render breathing difficult. Its excessive vascularity renders wounds of the tongue a source of serious hemorrhage, which frequently requires ligation of the lingual artery; hence the caution given by surgical authors to inexperienced operators in performing the trivial operation of the division of the frænum of the tongue in children. A peculiar condition of the tongue, in which a *furring* of its *lateral half* is detected, may often be a point of great diagnostic value, since it indicates irritation of some of the branches of the fifth cranial nerve or of the glosso-pharyngeal nerve. Thus, Hilton reports a case where furring of the posterior portion of the lateral half of the tongue followed an attack of tonsillitis from irritation of the glosso-pharyngeal nerves; and another where the removal of a decayed molar tooth caused the disappearance of a similar condition affecting the anterior half of the lateral part of the tongue, which had for a long time withstood all other methods of treatment, since the irritation of the fifth nerve had not been relieved. Bransby Cooper reports a case where the furred tongue persistently remained upon one side after fracture of the base of the skull involving the foramen rotundum; and a similar case recorded by Hilton was produced by disease of the Gasserian ganglion, which was detected at the autopsy. Such cases as these cannot fail to excite interest in the reader and to impress the importance of the bearings of nervous distribution as an aid in diagnosis.*

In operations for the removal of tumors of the tongue, if situated near to its base, an incision through the soft tissues forming the floor of the mouth is sometimes required in order to permit the tongue to be drawn below the chin and thus be more completely exposed. Care should, however, be exercised, after the soft tissues have thus been divided, to prevent the tongue falling or being drawn backward over the superior opening of the larynx. This can be easily accomplished by passing a loop of silk through the tip of the organ, by which its movements can be easily controlled.

If we look beneath the tongue at the attachment of its frænum, we can perceive the openings of the ducts of the sublingual glands; and the orifices of the submaxillary glands (ducts of Wharton) can be detected as two small papillæ on the anterior margin of the frænum. A swelling is often produced underneath the tongue by occlusion of the sublingual ducts, to which the term "ranula" is applied, since such a tumor is normal in the frog. The saliva also sometimes deposits sabulous matter, and gives rise to concretions, which are usually situated in the ducts themselves.

The palate is composed of two portions, the hard or bony structure formed by the palate-plates of the superior maxillary and palate bones, and the soft palate, which is composed of mucous membrane and muscles. The soft palate extends across the back of the mouth from side to side, being attached to the posterior margin of the hard palate above, while its inferior or free margin presents, at its centre, the projecting uvula, which is from half to three-quarters of an inch long in the healthy state.

---

* Essentials of Anatomy, 1880; Medical Record, October 15, 1880.

* New York Medical Gazette, October and November, 1880.

The physiological action of the soft palate is chiefly confined to its valve-like obstruction to the upper portion of the pharynx during the act of deglutition, which thus prevents the regurgitation of food, and especially that of liquids, into the posterior nares during the contraction of the constrictor muscles of the pharynx. It also modifies to some extent the intonation of the voice, as is demonstrated in those cases where it is congenitally defective. It is abundantly supplied with mucous follicles, which afford an anatomical explanation of the peculiar appearance which that portion presents when inflamed, since it is then covered by an excessive secretion of mucus, which frequently gives it a whitish color. The muscles of the palate play an important part in its movements, and, in the various operations for fissure of the palate, a close *study of the action of these muscles* is essential to a successful result, since, frequently, some of them have to be divided in order to insure a close approximation of the edges of the wound by suture.

The palate may be the seat of *hypertrophy*, as occurs chiefly in elongation of the tonsil; of *ulceration*, as is particularly liable to occur during the first stages of secondary syphilis, and in scarlet fever and small-pox; and of *tumors*, both of the benign and the malignant character. It may be made to *bulge forward* into the mouth by nasal polypi which protrude into the pharynx, by fungoid growths from the neighboring regions, or by retro-pharyngeal abscess, which is usually dependent upon caries of the cervical vertebræ. Perforation of the soft palate is liable to create considerable difficulty in the swallowing of liquids, in case the abnormal opening be of appreciable size. Most of the movements of the soft palate are produced by means of the glosso-pharyngeal nerve, or branches from Meckel's and the otic ganglion. Paralysis of the soft palate is therefore sometimes associated with paralysis of the pharyngeal, lingual, and labial muscles; hence, deglutition and articulation often become simultaneously embarrassed.

Many points of interest pertaining to the hard palate have been already given in connection with the bones, vessels, and nerves distributed to it,* and need not be here repeated.

The tonsils are small bodies situated between the anterior and posterior pillars of the fauces upon either side. They contain a central cavity, and are in close relations to some of the large vessels of the neck. During attacks of chronic inflammation, or repeated attacks of quinsy sore throat, effusions of lymph into the parenchymatous structure of these glands sometimes produce an induration and a permanent enlargement, which may be mistaken for scirrhus. The continuance of such an enlargement being a source of constant irritation, renders such patients extremely liable to inflammation of the throat on the slightest change of temperature; and, to relieve the sensibility, after the failure of all other means, an operation for their removal may become necessary. Suppuration within the tonsil, especially of both sides, if simultaneously attacked, may so close the fauces as to render deglutition impossible and even respiration difficult, unless by incision the accumulated pus be evacuated. The famous case reported by Desault, in which the carotid artery was punctured by an incision made into the tonsils, should lead all careful surgeons to remember that, in case extirpation of the tonsil be attempted, only that portion should be excised which *projects beyond the free border* of the stylo-glossus muscle, and that incisions should always be made with extreme care.

The occlusion of the ducts which open into the cavity of the tonsil may sometimes result in the formation of *calculi within the gland*, as was first described by Celsus.

The removal of portions of the superior maxillary bone, or, in severe cases, of the bone itself, is demanded by the growth of tumors, usually of a fungous or malignant character, and their encroachment on the surrounding bony structure of the mouth. Probably the earliest reference to the removal of this bone which is known to have been recorded is that of Acoluthus, a surgeon of Breslau, who is stated by Gensoul* to have removed a portion of the upper jaw for tumor in 1693, although Jourdan, in 1768, removed a portion of the antrum, and Dupuytren, in 1820, a portion of the alveolar process of the bone. This operation may be demanded as a means of relief for extensive disease of the antrum which depresses the roof of the mouth, for large polypi of the nose, as is reported by Mott in "Velpeau's Surgery," and for extensive necrosis or malignant growth. The severity of the operation, and the deformity which must ensue if the entire bone be removed, renders it evident that this operation should never be performed except in cases where no other means of relief is possible.

The *lower jaw* may be resected either partially or entire, although the latter operation may justly be regarded by surgeons as a most formidable operation. It was first performed by Graefe and Walther of Bonn, and has since been repeated by Dupuytren, Delpech, Carnochan, and others; but it is still a question whether the evils resulting from the loss of the entire inferior maxilla should not forbid its use.

In those instances where extensive necrosis of the lower jaw has occurred from phosphorus-poisoning, or where tumors have so involved portions of the bone as to impair its usefulness or endanger other parts, a partial resection of bone will often accomplish relief with less difficulty to the surgeon than if the entire bone be removed, and with far less evil to the patient.

In consequence of the effect of fissure of the hard palate upon the tone of the voice, as well as upon the enunciation of words, it becomes desirable to attempt its closure by uniting the two halves as soon as the individual is able to assist the operator in the efforts required for its execution; but, in those extreme cases where such union is impossible, mechanical appliances can often be made which will to a certain extent obviate the annoyances of the deformity.

False anchylosis of the lower jaw, dependent upon cicatrization or contraction of the soft parts, may exist to such an extent as to demand subcutaneous division of the masseter muscle. A case was reported by Dr. Schmidt, in 1841, where a young lady, in consequence of an extensively ulcerated throat when a child, had not been able to open her mouth for a period of twelve years, so that the end of the little finger could be inserted, and where recovery followed the division of the masseter muscle. Dr. Mott, in his edition of "Velpeau's Surgery," treats of this condition for the first time as a special type of disease, and reports seventeen cases where the condition was treated by forcible dilatation by various mechanical devices.

* Paris, 1833.

It may be advisable in this connection to again call attention to one of the axioms of John Hilton in reference to the nervous association which exists between the joints and the muscles which move them,* since by this useful guide some local seat of irritation may possibly be detected in such cases which will account for such fixation of the jaw, and which, when properly relieved, may be followed by a complete return of mobility without recourse to severer methods. This would, of course, not apply to any form of fixation dependent upon cicatrical tissue.

156 Madison Ave.

A CASE OF PERFORATING PISTOL-SHOT WOUND OF ANTERIOR WALL OF LEFT VENTRICLE OF THE HEART.

Sudden Death on Eleventh Day from Rupture at Point of Lodgement of Ball.

By M. M. ROBBINS, M.D.,

AURORA, ILL.

I was called about 4 o'clock P.M., October 22, 1880, to see J. B. W——, a machinist, aged fifty-seven years, who had been wounded by a pistol ball, and who was then in the condition of severe shock. He rallied fairly that evening, and on the following day reaction was excessive.

On examination, assisted by Dr. E. B. Howell, the ball was found to have entered the outer aspect of the left arm, at a point about five inches below the shoulder-joint, emerging about two inches below the axillary fold, passing anterior to the bone and not injuring it. It then struck the chest over the fifth rib, passed inward and slightly downward to the fourth costal interspace, and a little inside a line drawn perpendicularly from the left nipple. Beyond this point the probe would not pass. He improved quite rapidly. He had no pain except from a bronchitis which he had contracted previous to the injury. There were no special symptoms indicating that the ball had injured any vital organ.

On the eighth day after injury he was dressed. On the ninth day he was out of doors. On the tenth he walked about still more. On the eleventh he walked about for awhile in the morning. About ten o'clock he took a short ride in an easy carriage, and returning home, said that he felt better than at any time since his injury. During the afternoon he walked about or rested uponthe sofa as he felt inclined; ate a light supper about 6.30 P.M.; chatted awhile after eating; said frequently that, except being a little weak he felt better than at any time since his injury. He walked from the table to one corner of the room, sat down and immediately complained of a severe pain and pressure in his chest, in the cardiac region. He walked to another part of the room, the pain and distress continuing, and in a few minutes he was dead. It was estimated by different members of the family that he lived from three to eight minutes after the serious symptoms began, probably not more than the shorter time. He had lived eleven days three and one-half hours after the injury.

Post-mortem fourteen hours after death; present, Drs. Higgins and E. B. Howell. On opening the chest a considerable quantity of blood was found in the left pleural cavity, and the pericardium was filled with blood. About one-half of that in the pericardium was in the form of a recent clot; no old clots could be found. The ball had struck the upper border of the fifth rib, at the point to which we had traced it at the time of injury, described nearly a right angle with its previous course, perforated the pericardium, struck the left ventricle upon its anterior wall, about two-fifths of the distance from the base to the apex, passed into and through the ventricular cavity nearly horizontally, and lodged in its posterior wall, through which it nearly passed at the time of injury. At this point there was a stellate rupture. This was at the apex of a slight elevation upon the surface, the walls of which were very thin. It is possible that these walls had been thinned by the roughened surface of the ball after its lodgment there.

There were old adhesions of the pleural surfaces at the left of the heart, which accounted for the pain in that region which attended his cough; one of the aortic valves was ossified. This was the only lesion, referable to the heart, discovered before death, although careful examination was made for any symptom which would indicate that the heart had been injured.

The ball was 32 caliber. I am informed that he ran about fifty feet, after receiving the wound, before he became unconscious.

The wounds in the arm, chest, and anterior wall of ventricle were entirely healed. One of the pillars of the columnæ carneæ was located immediately over the point where the ball entered the ventricular cavity, and may possibly have prevented or helped to prevent the flow of blood through the wound.

A CASE OF ISOLATED RHEUMATIC INFLAMMATION OF PERICARDIUM CURED BY SALICYLIC ACID.

By WM. S. CHEESMAN, M.D.,

BROOKLYN.

Charles D——, aged seventeen years. The patient gave the following history: He had long been subject to shortness of breath on going upstairs. Two weeks before I saw him he was taken ill with chilly sensations, followed by pains in the bones and in his back. He had since suffered from dyspnœa, orthopnœa, and a slight cough. He had had one such attack before.

When seen on August 24th, he was pale and had anasarca of the feet. He complained of slight pain in the wrists, which were not and had not been swollen. Examination of the chest detected, about the junction of the fourth rib with the sternum, a double friction-sound, synchronous with the heart's beat. This was best heard when the patient lay on his back; it was inaudible when he sat up and leaned forward. The area of præcordial flatness was much increased. It extended about half an inch beyond the sternum to the right, and beyond the apex-beat (which was very faint) to the left. There was flatness above as far as the third rib. Temperature, 101¼°

The next day a beautiful erythema maculatum appeared all over the body and limbs. The physical signs remained the same. Temperature in the morning, 101°; in the evening, 101½°. To have salicylic acid, grs. xx., every two hours, except at night.

During the following day his temperature ranged about 100°, but on the day after it fell to 99°. He complained of tinnitus aurium and dizziness. Percussion showed the area of precordial flatness somewhat diminished, while auscultation revealed loud friction-sounds over the whole precordial area, and a friction fremitus was plainly perceptible on palpation. These friction-signs increased in intensity, the precordial dulness decreased, and the apex-beat came out stronger during the ensuing three days. All this time the salicylic acid had been continued (gr. xx. q.2.h.) and the temperature had remained below 100°. On the night of August 31st the patient became noisy and delirious. As there had been no increase of temperature, and as the inflammatory process was on the wane, the delirium was ascribed to salicylic poisoning, and the drug was stopped; whereupon the delirium passed into sopor and mental hebetude, which lasted a couple of days.

---

* Every nerve distributed to the muscles which move a joint sends a filament to the joint itself, and supplies the integument over the insertion of each of the muscles which move it.

On September 3d the area of cardiac dulness seemed normal, and the friction-sounds were much diminished in number and intensity. But with the recession of the signs of pericarditis, there came out more and more clearly a mitral systolic murmur, audible as far as the left posterior axillary line.

A slight rise of temperature which occurred about this time was reduced by salicylic acid, and left the patient feeling very well, the friction-sounds almost gone, but some anasarca of the feet, and a loud mitral regurgitant murmur remaining. No albuminuria or casts. Tr. digitalis ordered.

The patient was last seen on September 20th. The mitral murmur persisted, but examination failed to detect other evidence of any morbid condition in the chest.

The interpretation of this case I take to be as follows: For years the patient had had mitral disease of rheumatic origin, which caused his shortness of breath. Acute rheumatism had now attacked him a second time, but instead of affecting his joints, an inflammatory effusion into the pericardium took place. Like an ordinary rheumatic arthritis, this condition, as well as the fever, was removed by salicylic acid. As the effusion was taken up, the roughened surfaces of the pericardium played upon one another, producing the friction-sounds and fremitus; and as these grew fainter through removal of inflammatory deposits or agglutinations of the visceral and parietal surfaces, the old mitral murmur began to be heard.

The main interest of the case centers in the fact that a true rheumatic inflammation had attacked the pericardium *alone*, and was controlled by salicylate of soda.

In addition, it is an instructive fact that delirium may be caused by salicylic acid. This is now pretty well known in our hospitals, but has not yet found its way into text-books; yet it is none the less a fact. I have notes of a case of rheumatism, in the treatment of which salicylic acid was pushed till delirium supervened, but ceased when the drug was discontinued. *As an experiment* the salicylic acid was repeated and stopped four times, always with the result of producing a delirium, which passed away with the stoppage of the medicine.

Diabetis Insipidus Cured by Ergot.—A case of this kind is reported by Dr. E. W. Saunders in the St. Louis *Courier of Medicine.* The patient was a woman, aged fifty-three years, who had suffered from polyuria for two years. She passed from eight to ten quarts of water per day, sp. gr. 1004. Under ext. ergot, fl. ʒ j., t.i.d., she rapidly improved, and in three months had made a perfect recovery.

Reports of Hospitals.

PHILADELPHIA HOSPITAL.

Notes of Practice and Peculiarities of Treatment.

Clinical Service of HORATIO C. WOOD, M.D.,

PROFESSOR OF MATERIA MEDICA IN THE UNIVERSITY OF PENNSYLVANIA, AND PHYSICIAN TO THE PHILADELPHIA HOSPITAL.

INJURY OF THE SPINE FOLLOWED BY SYMPTOMS OF FRACTURE — OBSCURE CASE OF APHASIA — DIAGNOSIS OF HEPATIC CANCER.

Case I.—*Injury of the spine, followed by symptoms of fracture, with autopsy.*—I find myself, gentlemen, this morning, in a dilemma, as the first case about whom I desired to lecture died just an hour or two ago. However, as the symptoms were of a negative character, I will occupy your attention for a few moments with their discussion.

The man came into the hospital with about this history: On September 28th he fell down a cellar-way, knew nothing after, until he came to his consciousness in a station-house, and found himself completely paralyzed in all parts of his body below the neck. He was brought to this hospital on the following day, at which time he began to suffer from severe pain in both legs and arms.

When I first saw him he was completely paralyzed as to motion; sensation was impaired, although not completely gone, and he had no control over the bowels or bladder. His respirations were about twenty per minute and purely diaphragmatic, and his temperature about 100°.

On October 2d there was a slight change in his condition. There was then complete loss of voluntary movements on right side, the left leg was weak but still capable of exercising all movements, and the left arm and fingers still retained some motion, while movements of head and neck were perfect.

Reflex action was retained in left leg but all gone in right; there existed incontinence of urine, and the bowels, though constipated, were not under control.

His respirations were deep, labored, and purely diaphragmatic. On raising him to a sitting position he had intense pain in the region of the sixth cervical vertebra. He complained of sore throat, but had no apparent difficulty in swallowing. When this man was first picked up you would have almost taken it for granted that he was suffering from concussion of the brain, or perhaps compression from fracture; as, after remaining in the ward, he regained his consciousness, but with such permanent lesions below a certain point in the neck (sixth cervical vertebra), and as when I sat him up he complained of such acute, sickening pain at that point, I concluded that there was a fracture at that point of the canal, although no evidences of it were brought out by the external appearances of the column.

Another evidence of a lesion high up in the cord is the absence of reflex motion. This could not be so if there was not some interruption to transmission of impulse to the centres in the medulla. The man went rapidly from bad to worse, and died this morning from exhaustion.

We will doubtless find, on a post-mortem examination, myelitis at that point, together with possible degeneration of the structure of the cord. At a post-mortem examination which was made, no distinct fracture was discovered at the position of the sixth cervical vertebra, but distinct evidences of concussion, with degeneration and disintegration of the substance of the cord, at that point.

Case II.—*Obscure case of aphasia.*—This woman, gentleman, has been an inmate of this hospital for some time, and came in with an unknown history.

You will notice as she lies on the bed that there is slight paresis of the right side of the face, and that the right leg is drawn up. Now, if I ask her in German "How old are you?" "How long have you been sick?" or any such question, note her reply: It is always "Yes," "No," or "Gott in himmel." She is fairly intelligent, can understand numerals when your fingers are held up, can always make her wants known, so that whatever she may have the matter refers to language and not to ideas.

A curious fact is developed when I touch lightly her right arm or leg; they seem to be excessively hyperæsthetic. This is slight in the arm, but much more marked in the leg.

We have, then, a case before us without any history, which offers these symptoms: right-sided palsy, with power over the muscles of the larynx and face, with loss of language but retention of ideas and no cephalalgia or localized pain in the head.

I think the attack came on suddenly. This I judge, although there is no history, from an inability to discover any progressive lesion of the brain; there only appears a damage wrought, but no progressive steps of a disease, the poor woman being here from day to day in exactly the same condition. There must be then a lesion of the brain in the nature of a clot or thrombus. Although we can suggest no means of diagnosis between a clot or thrombus, we are able, at least, to locate the position of the lesion.

You know that we have, separating the frontal and middle lobes of the brain, a fissure—the fissure of Sylvius. Bounding this is the third frontal convolution, which on the left side has been abundantly proved as the seat of language. This centre is compressed in a small mass of convolutions about the island of Reil. Now, any lesion of this island of Reil is followed by loss of language or aphasia, and almost invariably by right-sided hemiplegia.

It is a curious fact that these aphasias always retain their emotional language at the expense of all other. For example, if a person is addicted to swearing, when suffering from this disease he will often solely use his oaths with great fluency; or, as in a case I knew, the man being very religious, could drop upon his knees and recite the most fluent prayer; but on rising could not group two words together intelligently.

There is a dislocation between the ideas and words which is retained for the emotional language, but is lost for all other. It is a common thing for them to use their native language, although perhaps long in disuse. Here our case uses the expression "Gott in himmel" in her mother tongue.

Some time ago I met a case of this kind in an old lady in the city, who some months before her death talked incessantly in a curious jargon, to the consternation of those around her. This was quite unintelligible, until a linguist being present explained that it was Portuguese. It was not until then that it was discovered that in very early life she had lived in Brazil, and now, when under the strong stimulus of her disease, her mother tongue had welled up to the surface, although hidden for almost half a century.

Why this woman has this extreme hyperæsthesia I cannot tell, except there be some lesion causing an irritation of the brain centres, probably of the crus cerebri or the cerebrum itself.

Case III.—*Diagnosis of hepatic cancer from cirrhosis and abscess of the liver.*—This man, our next patient, is about fifty years of age, and came into the house early in September, suffering from irregularity of bowels, slight pain in the region of the liver, and incessant vomiting, which nothing seemed to relieve.

There were no chest symptoms or gastric tenderness, but percussion over the liver showed marked enlargement of that organ.

His history, in brief, shows that he was always a hard drinker, had had syphilis, and was considerably exposed to malarial influences.

As you see him before you there is apparent a distinct enlargement in the right and left hypochondriac and epigastric regions, and as I percuss the tumor, which is the liver, I can show you its edge extending down below the level of the umbilicus. As I grasp the organ it is resisting, and its edge very rounded and hard; while over its surface can be felt numerous hard nodules or fossilations.

When I first saw this man, I suspected, from his appearance and history, that he was suffering from chronic interstitial hepatitis. You know that when alcohol is taken in excess into the system, it produces two different results. First, should this alcohol be taken diluted, upon a full stomach, it will eventually produce fatty degeneration of the liver. The liver looking, upon a post-mortem table, large, yellow, smooth and fatty; but secondly, should this liquor be taken "straight," and, as is generally the case, upon an empty stomach, it is carried by the portal vein undiluted to the liver, where it acts as a direct irritant, setting up a chronic inflammation.

This is called chronic interstitial hepatitis or cirrhosis of the liver, or, owing to its prevalence in England, where gin is the national drink, gin-drinkers' or hob-nailed liver.

Now, I say, when I first saw this man, I thought that this latter condition was present, but as he stays in the hospital, the organ continues to enlarge gradually and does not take on the proper course of the last stages of cirrhosis, and, at present, has reached a far greater size than any case of that kind that I have observed.

It can be one of two affections, viz., abscess of the liver, or carcinoma of the liver.

I do not think it is an abscess, as he has no history of recurring chills or fever, no cause, such as dysentery or ulcerative change in the intestines, or acute disease of the liver. Abscess of the liver, moreover, is a very obscure and hidden disease, and is rare in this country. I have seen three or four cases on the post-mortem table, but never one which was diagnosed during life, although it is often recognized in hot climates, following acute hepatitis. I must, therefore, come by exclusion to the belief that he suffered from carcinoma of the liver.

This disease is usually associated with severe pain in the region of the affected organ. He has none at present, but did suffer a great deal prior to this time. This pain, however, is not necessary, as it is due, not to disease of the liver itself, but to an involvement of the capsule or covering of the organ, in fact a localized peritonitis. Then, again, this disease is often accompanied by jaundice. It is not in this case, nor ever is unless the position of the cancerous nodules is such as to press upon the hepatic ducts; hence, the absence or presence of jaundice is of little diagnostic value. To briefly sum up, I believe this to be cancer for the following reasons :

The rapid and continuous growth of the organ, its thick, rounded edges, its hard, unfluctuating, nodulated surface, the acute pain which was at one time present, the man's age, his emaciation and his cachectic appearance.

Treatment.—Under the supposition that he was suffering from chronic interstitial hepatitis, he was placed under the internal and external use of dilute nitro-muriatic acid, and direct treatment for his vomiting. For this present condition, none but general supporting treatment can be available. The course of this disease, of course, is toward a fatal termination, but as the diagnosis is only probable, not certain, care should be taken, as in all such cases, to make a guarded prognosis.

Progress of Medical Science.

Grave Febrile Symptoms following Exploration of the Rectum.—M. Richet reports this case, which is interesting on account of its rarity and of the lesson it teaches: The patient, a woman, was suffering from a stricture of the rectum, which bore all the appearances of being benign in nature. It was located a little above the anus, was almost circular in form, and interfered seriously with the passage of the fæces. For several days wads of charpie, smeared with an ointment of the bichloride of mercury, were kept in contact with the stricture, in the hope of producing absorption. A second digital examination was then made, and considerable force had to be used in order to get through the stricture. On the following day the patient had a violent chill, followed by fever, and her condition became very alarming. The chill was repeated at irregular hours, the liver increased in size, the appetite was lost, and the facies assumed a cachectic appearance. The patient had never had chills or lived in a malarious district, and all the symptoms, moreover, pointed to an embolism of the liver. After a time she began to improve, the fever stopped, the liver diminished in size, and the appetite returned. Although the patient could be considered out of danger, M. Richet did not dare to make another rectal examination; as, however, the passages are now regular and well formed, he believes that the stricture has been cured. —*Gazette des hôpitaux*, August 7th.

Maize and Maizenic Acid.—The following are the conclusions drawn by Dr. Vauthier in a brochure entitled: *Étude sur le maïs (Zea maïs) et l'acide maïzenique:*

1. The action of Zea mays is always favorable in all affections of the bladder, whether recent or chronic.

2. Maizenic acid is the active principle of the stigmata of maize, and it alone contains the therapeutic properties.

3. The diuretic action is not constant; it is met with in cases of acute traumatic cystitis and in cases of retention, but here the improvement in micturition is due to the recovery of the affected organs, and not directly to the action of the maizenic acid.

4. The best results are observed in uric and phosphatic gravel, in acute cystitis, whether simple or due to gravel, and in mucous or muco-purulent catarrh.

5. In the cases observed by the writer, the ordinary remedies for these affections had already been employed without benefit, while the maize never failed to effect a cure. In connection with the maize, simple and medicated vesical injections were employed.

6. The maizenic acid, moreover, has the power of dissolving calculi by its chemical action, and not only vesical calculi, but also all the other calcareous concretions that are met with in the human system. Hence its use seems indicated in cases of gout and rheumatism as well as in affections of the urinary organs.

The preparations used by the author were the infusion (10 parts of corn-silk to 100 of boiling water, with syrup *ad libitum:* dose, a tablespoonful every two hours), the extract in doses of one and one-half to three grains, and maizenic acid in doses of one-eighth of a grain in pill or mixture.—*Archives méd. Belges*, August, 1880.

Treatment of Menière's Disease by Quinine.—In 1865 M. Charcot recommended the systematic administration of quinine in the treatment of Menière's disease, and he now states that he has several additional cases of perfect cure obtained by this method of treatment. He lays stress, however, on the importance of administering the drug in large doses and for a prolonged period. He gives from ten to twelve and one-half grains daily, and even more if the patient can bear it, and continues its administration for a month, despite the apparent aggravation of the symptoms that the remedy generally produces at first. At the end of a month treatment is discontinued for fifteen days and is then resumed for another month, and, if necessary, it may be repeated a third time after another interval of two or three weeks. By this method M. Charcot has cured a lady who had already been subjected several times to a quinine treatment carried on without method.—*Gazette des hôpitaux*, August 14th.

Putrid Pleurisy with Sloughing of a piece of Gangrenous Lung.—Dr. Wagner, of Königshütte, reports the following case (*Berl. klin. Woch.*, Sept. 6, 1880): I. W——, aged seventeen, miner, was admitted to hospital suffering from dysentery. Croupous pneumonia supervened on the left side, and during convalescence from this attack he was seized with an acute left-sided pleuritis with effusion. In a few days the effusion was ascertained to have become purulent, and microscopic examination revealed the presence of countless bacteria. A large incision was made in the eighth intercostal space, near the vertebral column. The escaping pus had an offensive odor. In spite of antiseptic irrigation the odor of the escaping fluid became decidedly putrid, the temperature rose to 104°, and the patient's condition grew worse and worse. At this time, during renewal of the antiseptic dressing, a brownish mass appeared in the wound. Moderate traction resulted in bringing to light a piece of gangrenous lung, about three inches long and one inch thick, to which pleuritic false membranes firmly adhered. After this event the patient gradually recovered, although convalescence was somewhat interrupted by purulent retention and the expectoration of offensive sputa. At one time a large part of the injected fluid escaped by the mouth, and this phenomenon persisted several days. The explanation offered was that the newly-formed pulmonary cicatrix had become eroded by the retention of pus, and that a large bronchial tube had been laid open, thus effecting a direct communication of the pleural cavity with the mouth.

COMBINATION OF TURPENTINE WITH CHLOROFORM FOR ANÆSTHESIA.—Dr. Wachsmuth recommends the combination of a fifth part of oil of turpentine with the chloroform used for anæsthesia. The former agent exerts a stimulating action on the respiratory surface, and thus prevents paralysis of the lungs. It also increases the capacity of the pulmonary vesicles, and thus exposes a larger surface to the chloroform vapor, while at the same time a larger dose can be introduced without danger. This method is more agreeable to the patient, because it is more rapid, and at the same time has great advantages for the surgeon.—*Gazette des hôpitaux*, August 28, 1880.

VALUE OF CHLORAL IN PHTHISIS.—M. Ordylowski draws attention to the value of chloral in phthisis. His observations included fifteen cases, of which only two did not have cavities. The drug was given in capsules, in doses of fifteen to thirty grains at bedtime, and the patients then drank a glass of water. No bad symptom was noticed in any of the cases. The sleep was peaceable, the physical symptoms were less distressing in the morning, and the patients felt better and stronger, and never complained of cephalalgia. Whenever the chloral was discontinued the insomnia reappeared. The author claims that, in addition to relieving the insomnia, the chloral diminishes the night-sweats, checks somewhat the loss of weight, lowers the temperature, increases the urinary secretion, and improves the morale.—*Ibid.*

THE TERMINAL DISTRIBUTION OF THE NERVES IN THE UTERINE MUCOUS MEMBRANE.—Prof. Schröder, of Berlin, furnished Dr. Patenko with the freshly excised uteri of five women, and the latter has utilized this material for studying the nervous termination in the mucous membrane. Dr. Patenko states that in all these cases the operation was undertaken for primary cancer, but the malignant disease never extended above the os internum, and the microscopical and minute appearance of the uterine mucous membrane was always perfectly normal. He employed chloride of gold and osmic acid in solutions having a strength of 0.01 per cent. to 0.5 per cent. Portions of the specimens were subsequently placed in 96 per cent. alcohol, and used for thin sections. Other preparations were made by tearing small bits of tissue in the solutions mentioned. He makes a provisional statement of the results of his examinations. By suitable manipulations he succeeded in isolating some of the uterine glands, and a beautiful reticulum of delicate non-medullated nerve-fibres was seen in connection with the membrana propria. This network was situated above the external surface of the glands, and minute filaments were seen to proceed from it into the interior of the glands. These extremely delicate fibres were found between the endothelial cells of the membrana propria, or in the glandular epithelial cells. Their ultimate termination in the latter was not positively ascertained. The nodular points of the surface reticulum frequently showed small nerve-cells. The author believes that this network takes its origin from the nerve-fibres which course in the muscular substance of the uterus, and, accompanied by some intermuscular connective tissue, proceed to the boundary line of the mucous membrane.—*Centr. f. Gynäk.*, September 11th.

THE DEVELOPMENT OF FIBROUS BODIES IN THE OVARIES.—Dr. Patenko, of St. Petersburg, is engaged in studying the histogenesis of ovarian tumors. In a provisional statement of the results of his investigations the following conclusions are arrived at (*Centr. f. Gynäkol.*, September 11, 1880):

1. Ovarian corpora fibrosa unquestionably develop from corpora lutea. They may, however, also arise from follicles of incomplete maturity. During the progress of this development the primary follicles are, as a rule, destroyed by colloid metamorphosis.
2. Corpora fibrosa occur in two varieties: *a*, fibrous bodies containing an internal cavity; *b*, solid fibrous bodies, without any trace of such cavities.
3. Both kinds lack the capability of independent growth.
4. Fibrous tumors which actually grow from the ovaries may attain the size of a hen's egg, or, at the utmost, that of a goose's egg. In other words, their size never exceeds the dimensions which the ovary itself may reach under certain conditions.
5. In such cases the fibrous tumors are formed by a "flowing together" of the follicles and vessels of the ovaries. Both follicles and vessels are found to be in a condition of sclerosis.
6. The ovarian origin of the larger fibromata of the ovary is a matter of doubt.

[It must be confessed that the sweeping assertions of the author appear hardly justifiable from the limited number of cases he has examined. The ovaries of twelve women constituted his entire working material. The histogenetic origin of all kinds of ovarian tumors is certainly a promising field for more extended study, but any undue haste in arriving at general conclusions is even more reprehensible here than in many other microscopical investigations.]

A CASE OF RUPTURE OF THE TRACHEA THROUGH INDIRECT FORCE.—Dr. Wagner, of Königshütte, reports the following case: L. P——, aged nineteen years, railroad employee, sprang from a moving car, and falling, struck the left side of his neck against the brake. His neck was caught by the brake, his body was overturned, and he was dragged some distance by the rolling car. The head was violently pushed backward by this accident. When freed from his dangerous position, the patient experienced severe pains both at the back of his neck and in the anterior cervical region. He was, moreover, unable to move his neck. He was removed to a hospital, and the following was noted on his admission: active motion of head absent; passive movements cause him to scream with pain; fracture of cervical vertebræ not discoverable; no other abnormities. Cutaneous emphysema of the entire neck, the face, and upper pectoral region, was found ten hours after the accident. Respiration somewhat stertorous. Hollow-sounding cough, with expectoration of some fluid blood. Two fingers' breadth above the sternum a painful spot is found. Deglutition unimpaired. Pulse feeble, 120. Temperature normal. The patient soon began to improve, the emphysema gradually subsided, the cough abated, the cervical mobility was slowly restored. After a few days a hard mass was distinctly felt below the chin. It had the size of a hen's egg, was painful to the touch, and showed considerable reddening of its cutaneous covering. A laryngoscopic examination revealed only congestion of the vocal cords and visible portion of the trachea. The tumor showed fluctuation after some time, and pus escaped on incision. The patient finally completely recovered. The writer explains that this case was undoubtedly an instance of transverse rupture of the trachea, caused by the violent backward pushing of the head.—*Deut. med. Woch.*, Sept. 4, 1880.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, November 27, 1880.

THE HOSPITAL SUNDAY FUND.

As the time approaches when charitable contributions will be made to the different hospitals of our city, strenuous efforts are being made to popularize the movement and to increase its sphere of usefulness. In these directions the projectors of the scheme have much encouragement for continued exertion, and have good reasons for hoping that the amount of collections for this year will be greatly in excess of those of last. A permanent organization has now been formed, and the proper measures are being taken to systematize the work. It has been thought best, at least for the present, to allow each donor to designate the hospital to which he prefers his gift shall go, while the sums which are not designated shall be distributed according to the special needs of the hospitals on the list. As these needs are measured by the actual amount of charitable aid afforded to the sick, the system of division is eminently just. Last year the sum of twenty-six thousand dollars was collected in this city and distributed among fifteen hospitals. Although this was not as much as was expected, still, considering that the project was a new one, and that it had been before the public but a comparatively short period, the contribution was a very substantial one.

Since that time two more hospitals have joined the association, making the total seventeen. The list now includes all the larger institutions, with the exception of the three under the charge of the Roman Catholic sisterhoods. These charities have a system of their own for collecting funds, and have not responded to the invitation of the committee.

Judging from the present outlook, the amount of contributions will be very much larger than last year. The project has already taken hold of the public heart, the charity is considered a laudable one, and its management is beyond reproach. Still there is room for much more work in popularizing the scheme, a fact which the association is not slow to appreciate. Already the Secretary, Rev. George S. Baker, has issued a circular to the mayors of the larger cities, asking for the adoption of a system of hospital relief similar to our own, and suggesting that the contributions be made on the same days as here. To these requests several encouraging answers have been received, showing the interest felt in the general movement.

Some mayors have stated that there is no special reasons for such contributions in their vicinity, inasmuch as the hospitals are supported from the tax levy. While this may be a good reason why local organizations are not needed, it is an argument in favor of directing such contributions as might be obtained from such quarters to a general fund for distribution in needy quarters. In fact, we believe that Mr. Baker's project looks toward the formation of larger and more representative organization, which may eventually take charge of an annual hospital fund, to be distributed to hospitals not only in this, but other large cities. The advantages of such an organization would be that those who are inclined to be charitable to the sick poor, and who have no particular demands upon them at home, may be assured that their contributions would be judiciously distributed in other and needy quarters.

Eventually, also, when Hospital Saturday and Sunday grow in popularity, the public will be trained to direct these alms to a common fund, and thus cause a more equable distribution than at present. This will enlarge the usefulness of the association by giving it the fullest possible authority for discriminating between the wants of the different institutions, and making their awards accordingly. At present there are no means of doing this, except with a small proportion of the general fund. If it were otherwise, some of our hospitals would be stimulated to show more of a charitable disposition, and not, on the plea of want of funds, restrict the number of their free beds, and narrow their benefits to such only as choose to pay for them.

THE CHLOROFORM MORTALITY IN ENGLAND.

THE last announcement of a death from chloroform in England follows so closely upon a previous one that attention is naturally called to it. Great Britain is the birthplace of chloroform, and she has tenderly nursed the bantling until now it appears to have developed into something like the *monstrum, horrendum, ingens*, etc., of the Virgilian epic. In the year 1879, the English medical journals reported nine deaths from chloroform, while up to October of the present year there were chronicled seven more deaths from the same cause. These statistics are entirely unofficial and can hardly represent the total mortality from the anæsthetic. Most of the cases occurred in hospitals. Where post-mortems were made the organs, as a rule, failed to show any very satisfactory reason for death apart from the direct effects of the anæsthetic. If the reports may be believed, the chloroform was given in every case with the utmost care; and prompt measures for resuscitation were taken when the victim showed signs of collapse. One can hardly help the conclusion that the English surgeons think it a necessary part of their routine duties to kill from ten to twelve persons every year in order to perpetuate the use of chloroform.

There is in England a very exuberant development of emotional philanthropy. Just now it vents itself largely in anti-vaccination, anti-vivisection, anti-contagious disease societies, etc., which organizations occupy themselves in a kind of dithyrambic agitation of questions that are quite beyond their mental grasp. We venture to suggest that if all this organized activity were turned against chloroform, some good might be accomplished, or at least very little harm could result, which is more than can be said for the society now. There does not appear to be any valid reason why English surgeons should continue the practice of sending a dozen persons annually on their long journey, simply because chloroform is convenient and has the authority of long usage.

ANNUAL REPORT OF THE SURGEON-GENERAL OF THE U. S. MARINE HOSPITAL SERVICE.

In making some remarks upon the subject of the marine hospital service a year ago, we referred to its rapid growth as a medical service and the great promise it gave of future usefulness and importance. The report of the Surgeon-General for 1879–80 has just been received, and the record it gives of the past year's work abundantly justifies the prognostications that have been made. Under the skilful and energetic guidance of Dr. Hamilton the work of the Service has been enlarged in every direction. The number of patients treated during the year was 24,860, an increase of nearly four thousand upon the previous year. In addition to this there have been two new hospitals and twenty-three new dispensaries established. One of these hospitals, the largest in the Service, is located on Bedloe's Island, New York Harbor, and has an average of over one hundred patients in it.

Another important measure, secured largely by the activity of the Surgeon-General, is the compulsory examination of pilots for color-blindness. The regulations requiring such an examination went into effect last spring. Up to June 30th 2,870 pilots had been examined and sixty-four found color-blind, which gives the low ratio of .022 per cent. These statistics, however, are not yet complete or conclusive. There are estimated to be over fifty thousand pilots in the country. When they have all been examined, the service will have a mass of statistics which cannot fail to be of great value as regards the question of color-blindness. Some opposition has been excited by the adoption of these compulsory examinations, and their utility has been questioned. Such opposition, however, can proceed only from the uninformed. The facts of color-blindness are perfectly established, and, when it is remembered that there are probably three thousand collisions every year among merchant vessels, the necessity of excluding color-blind pilots from the control of such vessels needs no argument.

The compulsory physical examination of all seamen previous to shipping is a measure strongly recommended in the report. It is shown that since 1873 there have been 14,468 persons treated by the service who were physically incapacitated for the work of seamen; yet most of these were shipped on various vessels, adding by their presence to the risks of the crew and the ship.

Dr. Hamilton gives a table showing the progressive severity of the examination-tests for admission to the service. At the last examination, in 1880, the per cent. of rejections was $82\frac{14}{23}$. A specimen examination-paper is given, which shows that this ordeal, like that of the army and navy, need not alarm any one who has the ambition and industry to prepare for it thoroughly.

One other noticeable point in the present document is the arrangement of the medical and surgical statistics. These are fuller than they have ever been before, and they are tabulated in such a way that they must prove of much practical value.

Dr. Hamilton asks for legislation transferring Bedloe's Island from the War to the Treasury Department. This is a measure urgently needed for the good of the hospital and of the seamen at this port. It has been favorably reported on by a Congressional Committee, and it is expected that early and favorable action will be taken during the coming session.

Looking at the state of the service, as presented to us in the present report, we cannot but congratulate Dr. Hamilton upon the marked improvements in discipline, efficiency, and amount of medical work which he has already secured during his second year of office. This prosperity of the service is the best endorsement that can be given of the character and efficiency of its officers.

SMALL-POX AND VACCINATION.

It would appear to be a work of supererogation to remind the profession of their duty in respect to vaccination, were it not that common things are forgotten unless we are occasionally reminded of their existence. The number of cases of small-pox reported each week to the Board of Health for the last two or three months affords such a reminder. Several of the neighboring cities have been, and still are, the seats of this dread disease, in a more or less epidemic form. Cohoes, Brooklyn, and Philadelphia have been scourged by it, while in San Francisco it is still raging. When the closeness of communication and the constant intercourse between this city and the places above-mentioned is borne in mind, it is a marvel that it has not spread here. Its failure to find a foothold here is not due to lack of opportunity for invasion, but to the vigilance, promptness, and diligence of the Board of Health. Whenever a case has been discovered, it has been at once isolated or removed, and experienced physicians have been sent to vaccinate all in the immediate vicinity whom it was possible to reach.

But these measures, though apparently sufficient to meet the emergency, are not by any means all that is needed, or all that is to be desired. The profession should not allow itself to be lulled into fancied security by the immunity from an epidemic which New York has enjoyed for a number of years. There is only one way by which small-pox can be effectually stamped out, and that is by having everybody vaccinated. But the health board can reach only the poorer classes—those living in tenement-houses or who go to school; a small number compared with those who refuse to avail themselves of the privileges offered by the board, and who depend upon the protecting care of their family physicians. It needs no argument to prove that in many such cases their reliance is upon a broken reed. This neglect of his duty on the part of the family physician arises, in most cases, from simple forgetfulness or carelessness. This is, however, by no means the excuse in all cases, and with shame must it be confessed that there are among the reputable physicians of this city some who, either because they know no better, or for other reasons best known to themselves, pander to and uphold the ignorance and prejudice which the spread of knowledge and enlightenment has not yet rooted out from among the people. So great an obstacle has this been found by the Board of Health that Commissioner Janeway, in a recent report to the county society, as a member of the Committee on Hygiene, called the attention of that body to the subject, and suggested that the censors should take the matter in hand.

The prejudice against vaccination among certain classes is founded on a belief that certain diseases, notably scrofula and syphilis, can be inoculated with it, and a fear of the severity of the sore produced. Without attempting to discuss or decide the former question, even the possibility of such transmission may be avoided by using only bovine virus, as is proven by the experience of the board. In addition to the undoubted purity of this lymph, the vesicle caused by it runs a regular and definite course, and, if undisturbed, is not apt to lead to a very sore arm. Moreover, it is reliable when properly used, and can be obtained fresh, and the supply can always be propagated. Cool weather is the best time for vaccination, and, unless in an emergency, the operation should not be performed in hot weather on a child that is not in good health, or when erysipelas seems to be prevailing. A failure in the first attempt at vaccination is in most cases the fault either of the virus or of the vaccinator. It is true that some people are more susceptible to the virus than others, but a failure on the first or second attempt should not be looked upon as an indication that the patient cannot be vaccinated, and is therefore not liable to contract small-pox. It is the opinion of the most experienced vaccinators that everybody can be vaccinated at least once, which is the strongest argument in favor of repeating the operation upon a fresh subject as often as may be necessary, till it succeeds.

But after a time, usually estimated at seven years, but varying with the individual, the vaccination loses its perfect protective power and requires to be renewed. After a man has once had the benefit of a good vaccination, though it be many years before, if he should contract small-pox, it is not so severe as in the unvaccinated, and not so apt to prove fatal. The statistics of every epidemic show that the mortality from the disease is in inverse ratio to the number of times that the individual attacked had been vaccinated. This will, perhaps, best be seen by a glance at the following figures, collected by Mr. Marston during thirty years' experience in the London Small-pox Hospital:*

Classification of patients affected with small-pox.	Number of deaths, per cent.
1. Unvaccinated	35
2. Stated to have been vaccinated, but having no cicatrix	23.5
3. Vaccinated:	
a. Having one cicatrix	7.73
b. " two cicatrices	4.70
c. " three "	1.95
d. " four or more cicatrices	0.55
4. Having previously had small-pox	19

From these facts and figures it will be seen that if a person who has once had small-pox contracts the disease again, he is much more liable to die than one who has been vaccinated, even though but once. They also point out, as plainly as could be wished, not only the utility of primary vaccination, but also the equal necessity for revaccination at comparatively frequent intervals thereafter. There is but one way of finding out whether revaccination is necessary or not, and that is by trying it. If it does not take, the previous vaccination is still in good force, the insignificant scarification heals in a few days, and there is no harm done. If it does take, it shows that the patient was liable to contract small-pox and it was well for him that the vaccination was renewed.

* Reynolds's System of Medicine, vol. i., p. 168. Philadelphia, 1879.

We are aware that most, if not all, of what we have said above, is, or should be, known to every member of the profession, but daily experience proves that if such is the case, the knowledge is not applied, and it seemed to us fitting to remind our readers of the grave responsibility which rests upon them now, when the disease is in our midst, and when the time of year is favorable to vaccination.

Reports of Societies.

NEW YORK ACADEMY OF MEDICINE.

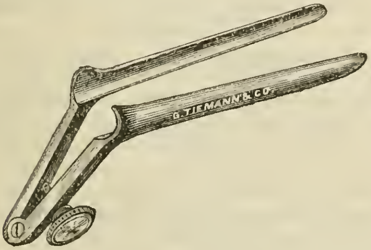
OBSTETRIC SECTION.

Stated Meeting, October 28, 1880.

DR. SALVATORE CARO, CHAIRMAN.

A NEW FEMALE URETHRAL DILATOR.

THE Chairman exhibited a female urethral dilator which could also be used as a speculum. An objection that might be made to the instrument, namely, that the walls of the urethra might fall between its blades, could be overcome easily by introducing a probe and pressing the mucous membrane back. As was noticed, the instrument dilates more at its distal than its proximal extremity, a fact that favored dilatation of the urethra without doing injury to the meatus.



DR. CARO reported two cases in which the instrument had been used with satisfactory results. A maiden lady, aged forty years, was taken with pain in the left hypogastric region. It recurred with each menstrual period and existed only during that time. Finally, she began to have painful micturition. Her urethra was dilated, and four small calculi removed from the bladder. The dilatation was not painful, and the recovery was complete. The second case was that of a young woman who began to suffer from painful micturition soon after marriage. The urethral and vaginal irritation became so great that sexual intercourse was impossible. There seemed to be a spasmodic irritation of the urethra; there was no evidence of inflammatory action, and a single dilatation relieved the patient at once of all discomfort. The dilatation was carried to the extent of about half an inch, when the instrument was allowed to remain in position, and it was soon expelled spontaneously.

DR. ISAAC E. TAYLOR remarked that the dilator presented by Dr. Caro was similar to an instrument which the late Dr. George T. Elliot and himself employed for examining the os uteri.

DR. A. C. POST stated that he was the first to treat vaginismus by stretching the vagina. He also referred to one case of *stricture of the female urethra* which he treated successfully by dilatation.

DR. LIVINGSTON referred to a case in which a lever-pessary had so compressed the urethra as to produce a partial but permanent obstruction of the canal.

INVERSION OF THE UTERUS OCCURRING IN A VIRGIN.

DR. I. E. TAYLOR reported a case of inversion of the uterus occurring in a patient aged forty years, whom he saw with Dr. Polk. There was not any evidence whatever that the woman had ever been impregnated. The uterus was about the size of a large orange. The inversion was complete. Dr. Taylor believed that the inversion had been gradual in its development, and that it began in the cervix.

ABORTION IN THE TENTH WEEK OF PREGNANCY WITHOUT HEMORRHAGE.

Dr. Taylor also reported a case in which a patient thirty-five years of age had unusually severe pains during an abortion, and almost no blood was lost after the delivery of either the embryo or the placenta. After the embryo had been expelled, examination revealed a closed cervix. Laudanum was administered to modify the pains, which were exceedingly severe, and the patient was allowed to remain undisturbed. The placenta came away on the second day without hemorrhage, and there was no bloody discharge subsequently.

PREGNANCY UNDISTURBED BY MANIPULATION AND THE INTRODUCTION OF INSTRUMENTS INTO THE UTERUS.

Dr. Taylor also referred to a case in which the patient had one menstrual period after marriage, and subsequent to that had a slightly colored discharge, occasionally what seemed to be membranous remains passed off, and after a few days she flowed very freely. During the treatment to which she had been subjected, the case having been regarded as one of endometritis, the uterine sound had been introduced, sponge-tents had been used, and various applications had been made to the cervix, yet abortion did not occur, although it was afterwards established that pregnancy must have existed at the same time.

CASES ILLUSTRATING THE EFFECT PRODUCED BY CHLOROFORM IN LABOR.

Dr. Taylor also narrated a case in which labor began at 5 A.M., and at about 5.30 the os was found to be about the size of an old-fashioned sixpence. The pains were severe and continued so throughout nearly the entire day without increasing the dilatation to more than what would be represented by a two-shilling piece, and finally they were quite irritating. He put the patient under the influence of chloroform, and within an hour she was delivered of a large, healthy child, weighing eleven pounds. The case illustrated the stimulant effects of chloroform. In another case the woman had been thirty-six hours in labor, and the head was upon the perineum. Chloroform had been given for several hours, and also ergot, of which Dr. Taylor was not made aware. He directed that the chloroform be withheld, and the child was rapidly delivered. There was no post-partum hemorrhage. The uterus was as round as a ball, and hard. The ergotic contraction had followed the partial removal of the anæsthetic.

DR. LIVINGSTON remarked that he never gave chloroform in labor to the production of complete anæsthesia. He also referred to a case in which uterine pains ceased *entirely* whenever he entered the patient's room: and the phenomenon was repeated three or four times. He placed the woman partially under the influence of chloroform, and the labor progressed without further abnormal delay.

Dr. Livingston also referred to a case in which he was able to utilize a certain fact to his obstetric advantages. He was called in consultation to see a woman who had been in labor for some time, and in efforts at effecting delivery the head had been left in the cavity of the uterus, it having been separated from the body of the child by traction. The woman's pelvis was deformed. After making several unsuccessful efforts to catch the head, he noticed that, when the chloroform was partially withheld, the head occupied a comparatively fixed position, and he utilized that fact, withheld the anæsthetic, the head was grasped and held by the uterus sufficiently firm so that he was able to introduce the trephine, subsequently the cephalotribe, and complete the labor. It was the second case he had seen in which the head of the child had been separated from the body and left within the uterus.

Dr. Taylor referred to Dr. Goodell's statement, that a traction force of 200 pounds was required to pull the child's head off; and that he (Dr. G.) had never seen an instance in which the head was left within the uterine cavity. Dr. Taylor had seen three such cases, and he thought that if 100 pounds of traction force was applied there was very great danger of pulling the head of the child off.

SPONTANEOUS VERSION.

Dr. Taylor also referred to a case, similar to several he had encountered, in which spontaneous version occurred *after the waters had been evacuated four or five hours*, and an attempt to deliver with the forceps had failed.

ABDOMINAL TUMOR—TAPPING—REMOVAL OF PURULENT FLUID—TEMPORARY RELIEF.

Dr. A. C. Post narrated a case as follows: A woman, aged sixty years, came to the Presbyterian Hospital from West Virginia, with a large abdominal tumor, and expected to have ovariotomy performed. After careful examination the conclusion was reached that it was a compound tumor of the uterus, composed of solid and fluid substance, and tapping was advised. The tumor was aspirated, and seven pounds of fluid, largely purulent, were removed. There had been no distinct inflammatory symptoms before, and there were none afterward. A compress and bandage were placed about the abdomen, and no unpleasant symptoms followed. The patient was very much relieved, and, a few weeks subsequently, returned to her home, feeling quite comfortable.

CASE FOR DIAGNOSIS.

Dr. Livingston related a case with the following history: An apparently healthy, robust girl, aged fourteen years, suddenly felt that her clothes were wet over the left hip and buttock. On examination, a liquid, like serum, was seen oozing from one spot, and about *two* quarts flowed out. The fluid appeared only during the day, and at night the flow abated. There was not the slightest change in the appearance of the skin as compared with that on any other part of the body, and the discharge gradually subsided. At the end of *seven* months the same thing was repeated. In the month of August (1880) it occurred for the *third* time, and about three weeks ago it appeared for the *fourth* time. Dr. Livingston then examined the patient very carefully, but, for the time, the discharge had ceased. He did not find anything abnormal. The next morning the discharge reappeared, and he then found, by the aid of a glass, a slightly enlarged follicle with an apparent opening, but it was not large enough to admit the end of the finest lachrymal probe. After using considerable force, the point of the instrument was made to enter slightly, fluid began to flow more freely, and had very much the appearance of synovial fluid, but it was not at all tenacious, nor were the clothes at all stiffened by being saturated with it, and afterward dried. The fluid could be seen coming out drop by drop, and so it continued to do until by evening eight or ten napkins had been wet thoroughly. He estimated the quantity of fluid discharged at two or three pints. He enlarged the opening so as to permit the introduction of the nozzle of a small syringe, and injected warm water, but not more than a teaspoonful could be made to enter, which gave the girl pain extending down her thigh. Otherwise she was apparently in perfect health. When *ten* years of age she slid down hill considerably one day, squatting and sliding upon her feet. The next morning she was taken with very severe pain in the left hip, but she recovered, after a short confinement in bed, and with the use of the limb perfect. She subsequently attended dancing-school, and it was not known that her limb was in any way unsound when the phenomenon referred to appeared.

THE NEW YORK SOCIETY OF GERMAN PHYSICIANS.

Stated Meeting, September 24, 1880.

Dr. Scharlau, President, in the Chair.

MULTIPLE UTERINE FIBROIDS, WITH CALCAREOUS DEPOSITS.

Dr. Tauszky presented the uterus of a colored woman, showing numerous interstitial fibroids in a condition of calcareous change.

Dr. Tauszky exhibited a second specimen, which consisted of a membranous cast of the uterine cavity of a young lady nineteen years of age. The lady in question was said to suffer from membranous dysmenorrhœa, and it was stated that a similar membrane was shed at each monthly epoch. The treatment of this affection was also alluded to.

REMOVAL OF STEEL SPLINTER FROM VITREOUS HUMOR.

Dr. Oppenheimer exhibited a patient from whose eye a steel splinter had been extracted with Gruening's magnet.

[This case has been already published in a previous issue of the Record.]

LARGE UTERINE FIBROID.

Dr. Scharlau presented a large uterine fibroid which he had lately successfully removed. He stated that the presence of the tumor had been recognized sixteen years ago by Dr. Kämmerer.

Dr. Kucher demonstrated the mode of application and action of Poulet's obstetric forceps (see Medical Record, Oct. 30, 1880, p. 498).

SUDDEN AMAUROSIS FOLLOWING THE ADMINISTRATION OF QUININE.

Dr. Gruening related this case, and stated that, in his opinion, the amaurosis was unquestionably the direct result of the action of quinine. The following history was given: Mrs. ——, aged thirty-five years, was obliged to have an abortion performed on her. Five days after this operation, the uterine cavity was scraped with a curette on account of the continuance of an ichorous discharge. This procedure was followed by slight hemorrhage. The temperature now rising to 106° F., the local treatment was supplemented by the administration in thirty hours of eighty grains of quinine. After a severe hysterical seizure the patient now suddenly became deaf and blind. In the course of twenty-four hours the patient's hearing returned. The eyes were at this time in the following condition: pupils dilated to their fullest extent, absolutely without reaction. The different media of the eye were normally transparent, but the papilla showed whitish discoloration, and the retinal vessels were considerably attenuated. The external portion of the retina was somewhat opaque, the macula distinctly red and projecting; absence of corneal anæsthesia. A few days later the patient stated that her vision returned for some time, but this was not proven to be the case. After three weeks, however, she was again able to see, but once more became blind with the reappearance of her menstruation. These occurrences were again repeated at a subsequent menstrual epoch. The patient then began to improve slowly, and, under the administration of nitrite of amyl, digitalis, iron, strychnia, and galvanism, fairly progressed to recovery.

In his further remarks upon such rare instances of quinine amaurosis, Dr. Gruening said that the prognosis of these cases was not unfavorable. The literature of the subject embraced five cases with partial recovery, *i.e.*, in all the field of vision remained permanently diminished. In the present instance, while central vision was perfect, the field of vision was narrowed, and in addition the patient was color-blind. The pupils also showed absence of dilatation after the use of eserin, but the normal calibre did not return with the cessation of the drug; they remained visibly enlarged. Light produced no effect upon their size, but during convergent motions reaction occurred. Finally, he said that the permanence of the diminution of the visual field was so characteristic of quinine amaurosis, that this alone would suffice to exclude sepsis, hysteria, and anæmia from the list of possible etiological factors in the present case.

DIPHTHERITIC EXANTHEMATA.

Dr. Jacobi related the history of a case recently observed by him, which he was inclined to regard as an instance of diphtheria accompanied by a peculiar rash. He stated that in former years such cases had more frequently come under his notice. To distinguish this affection from scarlatina with diphtheria, it must be remembered that the former was characterized by a rash lacking the uniformity of scarlatinous exanthemata, that it made its first appearance on the face and feet of the patient, that it frequently assumed the appearance of an urticaria sprinkled over with pustules of fluid contents. Moreover, the diphtheritic exanthem was not accompanied by the well-known appearances of the mucous membrane of the mouth and tongue. He also emphasized the additional point that diphtheria rarely made its appearance on the first day of an attack of scarlet fever. Diphtheritic exanthemata usually occurred in the early stages of the disease, commonly in cases remarkable for the absence of all septic symptoms. The hemorrhagic rashes of the later stages were of serious, often fatal significance. Thus Callimani reported 115 deaths in an epidemic of 200 cases.

Stated Meeting, October 22, 1880.

Dr. Garrigues, President, in the Chair.

Dr. Jacobi observed that the case of diphtheritic exanthem reported by him at the last meeting, subsequently turned out to be an ordinary case of scarlet fever, showing that strikingly characteristic symptoms may mislead one to form an incorrect judgment.

PERFORATION OF VERMIFORM APPENDIX.

Dr. Gleuck presented a specimen of the above, removed from the body of a boy aged seven years, who had recently fallen a victim to perityphlitis with perforation. The attack had been a very acute one, and had proved rapidly fatal. The appendix showed two perforations, and contained hardened fecal matter, embedded in which there were found poppy and anise seeds and grape-pits. It was thought probable that a slow ulceration without apparent symptoms had preceded the sudden perforation. The immediate cause of the latter was supposed to be a jumping of the boy from the back of his father.

Dr. Jacobi remarked that in children between three and eleven years of age, it was a normal occurrence to find a fold of mucous membrane at the entrance to the appendix, and that this fold, acting as a valve, would cause retention in the appendix of such particles as might accidentally have entered it. Moreover, it should be borne in mind that peritonitic adhesions frequently brought about permanent flexions of the appendix. The late Dr. Krakowitzer had expressed an opinion to this effect—that, as a rule, perforation of the vermiform appendix was preceded by local peritonitis.

Dr. Kucher stated that congenital flexions of this organ had also been observed.

Dr. Jacobi said that in future he would practise abdominal section and drainage, as soon as the diagnosis was fairly established in such cases. In answer to a question from Dr. Mantner, he added that he should not consider it necessary to ligate the appendix, because adhesions would be likely to close the perforated points as soon as antiseptic treatment was begun.

DOUBLE INVAGINATION OF SMALL INTESTINE, WITH ULCERATED MUCOUS POLYPUS.

Dr. Wendt presented a specimen of the above, which had been previously exhibited at a meeting of the Pathological Society. (See Medical Record.)

Dr. Jacobi thought that the ulceration caused by the intestinal polypus had produced a local paralysis of the muscular coat of the intestine, and that this had led to the invagination of the gut.

LARGE SEMI-SOLID OVARIAN TUMOR.

Dr. Wendt presented a specimen, consisting of a portion of an enormous ovarian tumor, successfully removed by Dr. Bopp, of the German Hospital. The history of the case, condensed from the hospital records, was as follows: Mrs. ——, aged thirty-eight years, has given birth to ten children. Menstruation, pregnancies, labors, confinements, were always normal. Last January she had an attack of peritonitis, but remembers no other serious disease. A tumor was first noticed after her last confinement, and from that time on her abdomen grew steadily larger.

On her admission to the hospital the abdomen was found to be enormously distended, and through its walls a fluctuating tumor was palpated. The surface was not even, and the consistence did not appear to be the same at all points. No fluid escaped after the introduction of a good-sized trocar.

On the 19th of April ovariotomy was performed in the ordinary manner, and under strictly antiseptic precautions. When the cyst was exposed to view, a large Spencer Wells's trocar was introduced, but no contents flowed out. The tumor had to be incised and part of its gelatinous and sticky contents removed by using the hand as a scoop. The tumor was found to weigh twenty-eight pounds. The broad pedicle was dropped into the pelvic cavity, and the wound closed by silver wire and catgut sutures. The progress of the case after the operation was favorable. Only on one day the temperature rose to 104° F. The patient was discharged cured in June. The examination of the tumor showed it to consist of many rounded partitions of various sizes, filled with a semi-solid, whitish, glistening mass, having in many places the appearance and consistence of white cerebral substance. Microscopically this mass was composed of variously-shaped epithelial cells, the majority of which showed colloid degeneration. Many of these bodies were also found in different stages of fatty degeneration. Portions of the tumor, when hardened in alcohol, shrunk to about one-tenth their original size, and microscopic sections then exhibited the following appearances: From the external fibrous capsule, ramifying trabecles of connective tissue proceeded inwards, growing thinner as the central portions of a partition were approached. These stalks of connective tissue had a single or double lining of long, slender, cylindrical epithelia, containing large, rounded or oval nuclei. Their protoplasm appeared homogeneous or faintly granular. Beyond this layer of epithelia a more or less homogeneous mass was found filling out the interspaces of neighboring trabeculæ. Here and there in this mass the delicate outlines of cells could still be discovered, showing that its origin was undoubtedly colloid metamorphosis of the lining epithelia. Many trabecles were quite vascular, and in some minute hemorrhages had taken place.

Tumors of this kind had been observed by Ohlshausen and others, but, when of large size, they had invariably proceeded from the parovaries, and were generally bilateral. In this case the tumor was of true ovarian origin, and this fact, together with its large size, constituted its exceptional nature. Another feature of interest was, that although the tumor contained no fluid, it had given unmistakable signs of fluctuation. Such tumors were called by German observers *cystoma papillare proliferum*, or simply *papilloma proliferum*. They were really proliferous adenomata with secondary colloid degeneration.

Dr. Caillé observed that he had met with similar microscopic appearances in the early stage of a cystic goitre.

Dr. Mantner called attention to the fact that Ohlshausen had inferred the parovarian nature of such rare tumors from the presence of ciliated epithelia, and asked whether this had been found in the present instance.

Dr. Wendt answered that a careful examination had failed to reveal their presence, and that there was not the least doubt about the ovarian origin of the tumor.

MODEL OF SPINAL CORD.

Dr. Seesel demonstrated an ingenious model, showing the course and direction of the various columns and fibres of the spinal cord.

Dr. Mandelbaum referred to three tracheotomies which he recently had occasion to perform. The first operation was upon a deaf-mute. Two weeks after the tracheotomy singultus occurred, which could be relieved by closure of the canula. In the fourth week the tracheotomy tube became clogged up with granulations. Speedy cure took place upon the removal of these. The second case was somewhat similar and likewise recovered. In the third case death took place.

Correspondence.

NARCOLEPSY.

A Seventy-two Hours' Sleep.

To the Editor of The Medical Record.

Sir—C. A. E——, aged twelve, came under my care May 21, 1880, on account of attacks of prolonged sleep. The seizures always came on about nine o'clock A.M., with severe nervous headache and drowsiness. He would lie down and immediately go into a deep sleep, which would continue forty-eight hours; then he would be troubled with nervous chills, but these would soon pass off and he would prolong his sleep, waking up at the end of seventy-two hours very much exhausted. During these attacks he could be roused at any time with a little effort, and answered questions intelligently, but would go to sleep again as soon as left undisturbed. He had a marked aversion for all nourishment; when waked up he would refuse to take any kind of food or drink, so they usually allowed him to continue his sleep unmolested. After an attack passed off, he would not remember anything that transpired while it lasted.

The first attack came on in the preceding September, nine months before I saw the case. All the attacks were uniform in character, and similar to the one above described. At first they came on once a month, and he would recover from the immediate effects of it in a few days, so that during the interval he would generally feel very well. But after continuing for a few months they became more frequent, returning every two weeks; then his general health became very much impaired, showing marked symptoms of nervous exhaustion. As the symptoms of neurasthenia afforded the best indications for treatment, he was given the usual remedies for this condition, and he responded very nicely, only having one mild attack afterward, though he had the nervous headache and other premonitory symptoms on several occasions. He has not had a return during the last three months. His maternal aunt is subject to petit mal, and his mother to severe periodic neuralgia, thus showing a neurotic tendency. Yet, some of his family are physically very large and long-lived. His grandfather is at present ninety-five, one of the oldest men in the city; he is a very large man, and vigorous for his age, and bids fair to pass his centennial year in good condition. The patient himself is very much overgrown; he is five feet six, and weighs one hundred and fifty. The physical expressions of neurasthenia, that are so easily recognized by a close observer, and yet so difficult to describe, were well-marked in this case and assisted very much in indicating the necessary treatment. The line that separates neurasthenia from the various lepsies is often indistinct. Frequently, patients vibrate from one side of this line to the other, and for a long time their morbid status may not be clearly defined. While this may be the case to some extent with this patient, yet the order and character of the symptoms, viz., severe nervous headache, followed by a deep and prolonged sleep, with forgetfulness of the occurrences of the sleep, are sufficient to make it a true narcolepsy.

The following case presents more clearly the symptoms that have heretofore been described as narcolepsy:

A. G——, aged forty, of full habit, came under care four months ago for a very severe attack of neuralgia with sleeplessness. The attack proved to be very obstinate, and during the second week the neuralgia and sleeplessness subsided, and was followed by epileptic vertigo. In a few days the vertigo began to alternate with an irresistible desire to sleep. While the attacks of sleep were frequent—as often as six or eight times a day—they were of short duration, only two to five minutes long. They occurred several times at the table, and a few times in company. Often when she would be very busy with her household duties, she would go to sleep for a few minutes, then wake up as fresh as ever. One thing that seemed peculiar in this case was the fact, that the attacks of sleep and vertigo were not associated, but actually occurred on different days, the one taking the place of the other. The vertigo was the most distressing, for the days on which it appeared she was compelled to remain sitting or lying down a greater portion of the time. She would suffer for several days alternately with these attacks, and then be free from them for a week or ten days, when they would return and go through the same order again. During the intervals she would feel quite well, but not as strong as before the attack of neuralgia, which was the beginning of the present indisposition. She had been subject to attacks of neuralgia for several years, but none of them had been as severe as the preceding ones.

If there is any doubt about these attacks being epileptoid, it will be removed by the following: her mother and sister are epileptics, both subject to the grand mal. These facts will assist also in the true classification of narcolepsy.

T. K——, aged eighteen, well nourished, inclined to corpulence, epileptoid headache, loss of consciousness, narcolepsy. She has been subject to severe nervous headache for several years. The attacks of sleep and unconsciousness were first noticed about a year ago, and have occurred at irregular intervals ever since. At first they were several weeks apart, but during last summer they would return every few days, and at this time there was a slight daily headache, most severe at the vertex. She has never had any symptoms of hysteria or convulsions. The attacks associated with the headaches have not been uniform. At one time, after suffering severely for an hour or two, she would go into a deep, unconscious sleep, lasting from five to ten hours, from which she could be roused with difficulty, but when awakened, would answer questions, obey instructions, take food or medicine as directed, and yet have no remembrance of them afterward.

At another time, with the headache, she would become unconscious instead of going to sleep, and while in this state, if allowed to do so, would attend to her ordinary household duties as usual, but in an uninterested or absent-minded way; and there was no intelligent mental register as to what she had said or done while in this condition. Then again, when suffering with headache, she would be seized with short attacks of sleep, lasting three or four minutes, and recurring frequently during the day.

While she had never fallen, yet whenever these attacks of sleep came on, she would sit or lie down and go immediately to sleep, and as soon as it passed off would continue whatever she was doing, as if nothing had occurred.

Since the attacks became more frequent, she has, just after one, a great fear of going out alone, but this passes off in a few days. Her father was subject to some kind of nervous attacks for several years, and died suddenly while away from home. One brother is a somnambulist, and the other one has a very peculiar subjective delusion.

As at present understood, the meaning of the term narcolepsy is an irresistible, morbid desire to sleep. Now, all the cases that I have thus far seen reported describe the sleep as of short duration; and yet, from the very nature of the disease, the length of the sleep cannot possibly be the controlling symptom. It is not the length, but the character of the sleep and the associated symptoms that make narcolepsy a distinct disease. As a variation in the length of the attack indicates only a difference of degree in epilepsy, so it must in narcolepsy also. While the sleep state is a very important symptom, yet it is by no means the only one present. The associated symptoms can be best studied during the intervals of the attack. The best diagnosis of a patient's condition is formed by a general summing-up of all the morbid indications present, rather than on a single prominent one. I believe our present imperfect knowledge of narcolepsy is in a great measure due to a want of discrimination of the disease rather than to its rarity. In the above cases the associated nervous phenomena are given in full to assist in a correct classification of the disease. Dr. Putzel, in a recent work on "Functional Nervous Diseases," classes narcolepsy under the heading of epileptoid sleep states, and I think this is the true position of the disease. There are several varieties of the lepsies that are being very diligently studied just now; and however important these branches may prove, yet they will doubtless continue to be classed with the family of epilepsy. Individuals differ in their morbid as they do in their normal, condition, each one having peculiarities that modify the development of disease. When a patient who is subject to narcolepsy is critically examined there will be found an instability of the nervous organization; and this degeneration of the nervous centres is always present in epilepsy. This instability of the nervous centres has physical as well as nervous symptoms. These morbid physical expressions belong as truly to the life history of epilepsy as do the loss of consciousness or the convulsions. The physical expressions of the disease occupy a very important place in the diagnosis of all the minor forms of epilepsy. When these patients are subjected to a close examination the physical indications of the disease can always be found, yet it is frequently inconvenient, and sometimes impossible, to see the most marked of the nervous symptoms. When narcoleptic patients are carefully examined they not only present the general characters of epilepsy, but the nervous instability, the physical indications, and the minor symptoms, all clearly demonstrate that they belong to the epileptic family. It is only within the last decade that the epileptoid states have been discriminated; and it is very probable that in due time narcolepsy will find its appropriate place among the minor epilepsies, and occupy the borderland between the epileptic and the non-epileptic.

Respectfully, Robert H. Porter, M.D.

Louisville, Ky.

BLOWING ON THE NEW-BORN A REMEDY FOR ASPHYXIA.

To the Editor of The Medical Record.

Sir—A few years ago I discovered that under ordinary circumstances blowing on the asphyxiated new-born babe would establish free and full respiration. I immediately adopted and continue to use this to the exclusion of the old methods of resuscitation.

Certainly it is not as cruel as spanking the babe. Surely it is more convenient than the alternate application of hot and cold water. It is also a readier remedy than "the battery," which only few possess, and which no one wishes to carry with him to every obstetric call.

This gentle blowing can be successfully directed to any part of the naked body, but most effectively to the abdomen, and, *mirabile dictu*, with a loud squall the asphyxtic babe will become a living soul.

Having read, a few days ago, in a report of his clinics, that Prof. Charcot blows similarly on his patients, to recall them from the somnambulistic state to consciousness, has prompted me to place on record my own blowing "wrinkle" for "this far more noble and glorious purpose."

Yours very respectfully, T. J. Hutton, M.D.,
Late Res. Surgeon, L. I. Coll. Hosp., Brooklyn, N. Y.

Fergus Falls, Minn., Nov. 10, 1880.

HEMIGLOSSITIS.

To the Editor of The Medical Record.

Sir—The rarity of hemiglossitis and our ignorance of its true cause makes it desirable to note every case of that curious affection. A. B——, a private of marines, aged twenty-seven years, under my care at the Naval Hospital, Portsmouth, in 1879, was admitted with sore throat and erysipelas. Five days after admission he was attacked with *right* hemiglossitis. The tongue was enormously enlarged, preventing swallowing and impeding respirations to such an extent as to require tracheotomy. In this case incisions were useless, rectal alimentation and stimulants were of no avail, and the patient sank rapidly, dying on the seventh day. De Mussy, Graves, and De Chambre mention several cases of this interesting disease, but in all of these the congestion was on the *left* half of the tongue, while in this case the hemiglossitis was on the *right side.*

Yours truly, C. J. Cleborne, M.D.,
Medical Inspector, U. S. Navy.

HAIR IN THE PUNCTUM LACHRYMALIS.

To the Editor of The Medical Record.

Sir—Twice provoked, I conclude to report an accident of which I have been the subject a second time, and which, with the exception of the case reported by Dr. Z. E. Lewis in the Record of February 14, 1880, is to me unique. My case-book shows that April 21, 1879, I examined my left eye for the purpose of detecting and removing a foreign body supposed to have lodged there. Finding none, I concluded that I was suffering only the inflammatory effects of some substance already expelled. As the disagreeable sensations continued, and I had developed quite a respectable conjunctivitis, the following day I appealed to one of my colleagues who on examination discovered nothing peculiar, with the exception of the conjunctivitis, for which he recommended a mild astringent collyrium. Shortly after, while examining the eye with a magnifying concave mirror, I detected the point of a hair just projecting from the punctum lachrymalis, the removal of which soon relieved me of my troublesome symptoms. Recollecting my previous experience, when looking for a foreign body in the same eye a few days since, I noticed the punctum, and to my surprise again found it occupied by one of the cilia, which I removed with good effect.

Very respectfully, etc., Dr. J. H. Glass,
Pres. Schuyler Co. (N. Y.) Med. Soc.

FACTS CONCERNING THE USE OF THE METRIC SYSTEM.

To the Editor of The Medical Record.

Sir—In the Medical Record of October 23, 1880, under the heading, "The Americanized Metric System," I find the statement that "most physicians appreciate these advantages" (*i.e.*, the advantages of the metric system). In the sentence following the above quotation, your correspondent of the 23d ult. states that "a majority of the pharmacists," . . . "are anxiously waiting the day when they can discard the time-honored drachm and ounce."

The statements quoted may obtain in some parts of the United States, but in New England I venture to say that not one physician in ten are using the original or "Americanized" metric system. It is possible that some very conscientious practitioners may refrain from employing the system because of the druggist's inability to compound the prescription exactly as it is written, but my personal knowledge of the men who use the new system leads me to doubt it. For instance, a friend when he has occasion to prescribe for patients living in the country, writes in the metric system, with the remark to his assistant that he should like to see the country druggist stare in his attempt to decipher it. I am aware that the authoritative voice of the American Medical Association has spoken in favor of the new system, but it is possible that a further experience will occasion a change in its dictum.

The result of inquiry in different Eastern States is, that most druggists who have procured new apparatus have done so at the request of one or more of their patrons, and not because of any desire on their part to do away with the old system of weights and measures.

To many who have familiarized themselves with the metric method, and have undertaken its practical application, the claims for preference over the old system have seemed to be entirely fallacious.

While there can be no doubt that many physicians are using the new system with the honest intent of advancing science, it is equally true that others of the profession do so to appear scientific and superior to their brethren who prefer to deal with facts rather than hypothesis. It seems to the writer that the profession have, to some extent, individually at least, laid aside the cloak of conservatism in regard to the metric system. It is a question if the "Americanized" plan would not interfere with the original intent of the new system, viz., an international system of weights and measures.

When the heads of the executive department of the United States unanimously adopt the system, it will be ample time for those who have the health and life of the American people in charge to change the "time-honored drachm and ounce" for the more elegant grams, 3.887 and grams 31.099.

C. S. Wheeler, M.D

Williamsburg, Mass.

New Instruments.

NEW OVUM AND PLACENTA FORCEPS.

By T. J. CROW, M.D.,

CARROLLTON, ILL.

For the removal of the products of conception in those cases of inevitable abortion where it is very difficult, if not impossible, to reach the ovum or placenta with the fingers, I have devised the instrument depicted in the accompanying sketch.

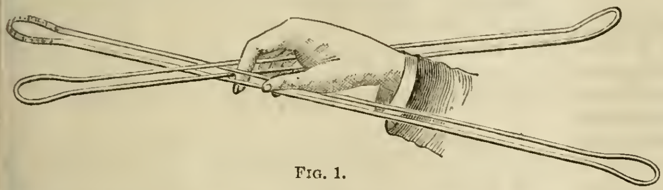


Fig. 1.

It is a double forceps made of steel wire, somewhat like two links of a chain, with the ends of the links properly shaped to make the blades of the forceps.

The blades are shaped like the blades of the common obstetrical forceps, the outer edges being brought to a thin, rounded edge, and the concave surface roughened like the surface of a file.

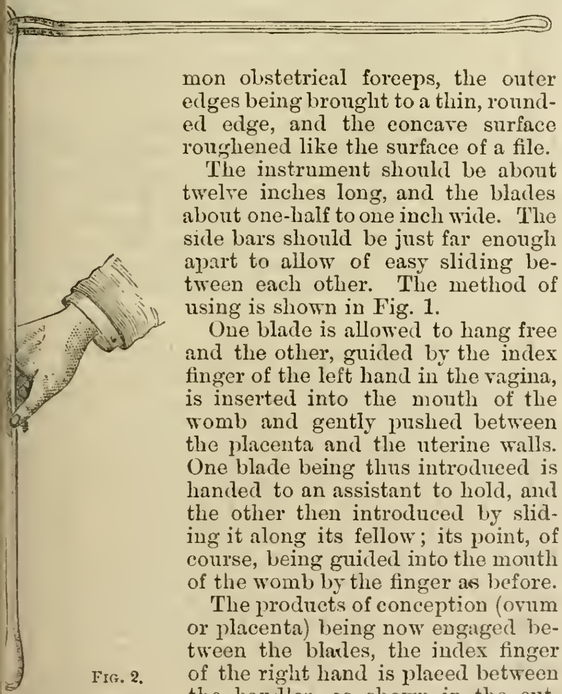

Fig. 2.

The instrument should be about twelve inches long, and the blades about one-half to one inch wide. The side bars should be just far enough apart to allow of easy sliding between each other. The method of using is shown in Fig. 1.

One blade is allowed to hang free and the other, guided by the index finger of the left hand in the vagina, is inserted into the mouth of the womb and gently pushed between the placenta and the uterine walls. One blade being thus introduced is handed to an assistant to hold, and the other then introduced by sliding it along its fellow; its point, of course, being guided into the mouth of the womb by the finger as before.

The products of conception (ovum or placenta) being now engaged between the blades, the index finger of the right hand is placed between the handles, as shown in the cut, and a fulcrum or hinge being thus formed the whole is withdrawn by gentle traction.

Instead of the finger, a piece of cork, sole leather, or soft rubber may be placed between the handles to make the fulcrum.

Very often the ovum, placenta, etc., may be removed by one blade of forceps used as a curette.

The instrument can be used for the removal of tumors, etc., from the womb, and I think (properly modified) would be very useful for the extraction of the stone in the operation of lithotomy. In fact, modified in size, shape, etc., according to the use intended to be made of it, it can be used wherever it is desirable to introduce one blade of a forceps alone, except that I do not think it would do very well for an obstetrical forceps.

I have extemporized a pair for the removal of a cherry-stone from a child's nose, out of two wire hairpins. If desirable, the instrument can be made with only two blades, and handles of any sort fastened to the instrument. If greater steadiness were desired the blades could be made with three wires, thus ——— ——) or the blades could be made solid. A fixed fulcrum could be had by one or more semicircular bends in the handles as thus ———⌒——— and a cork or bit of wood or rubber placed in the bend. When used in cavities too narrow to admit the finger (as the nares, or in gunshot wounds, etc.), a piece of cork, rubber, or sole leather might be fastened on the end of a wire and pushed down between the handles after the introduction of the blades. The forceps is easily made. Any blacksmith can make it. The first instrument I made use of was made of two loops of No. 12 wire from a tin shop.

The above are some of the uses of the instrument; others will suggest themselves.

◆

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from November 14, 1880, *to November* 20, 1880.

Taylor, M. K., Capt. and Asst. Surgeon. To report to Commanding General, Department of the East, for assignment to duty. S. O. 242, A. G. O., November 12, 1880. Assigned to duty at Fort Wayne, Michigan. S. O. 204, Department of the East, November 17, 1880.

Tesson, L. S., Capt. and Asst. Surgeon. Granted leave of absence for six months, with permission to go beyond sea. S. O. 244, A. G. O., November 15, 1880.

Brewer, J. W., Capt. and Asst. Surgeon. Died November 15, 1880.

Medical Items and News.

Contagious Diseases — Weekly Statement. — Comparative statement of cases of contagious diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending November 20, 1880.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro spinal Meningitis.	Measles.	Diphtheria.	Small-pox.	Yellow Fever.
Nov. 13, 1880.	0	21	102	3	11	73	3	0
Nov. 20, 1880.	0	19	132	5	19	150	5	0

The Entire Scapula was removed from a patient in Charing-Cross Hospital recently, for an encephaloid growth. The operation was done by Mr. Bellamy. There was but little hemorrhage, and the patient has been doing well.

Medical Practitioners in Brooklyn and New York.—At last accounts, the number of medical men registered in New York was nearly 2,500. The number in Brooklyn was over 700. If these figures are correct, the difference in the number of practitioners in Brooklyn and New York is quite a striking one. New York has a population of 1,203,823, while the population of Brooklyn is 566,689. The proportion of physicians to inhabitants, therefore, is in New York about 1 to 480, while in Brooklyn it is about 1 to 785. We present the statistics to young men intending to settle in the vicinity.

A Possible Legacy.—Philadelphia charities are in the way of receiving a great windfall. M. G. W. J. Reume, who recently died in that city, left a provision in his will to the effect that, in the event of the death of his wife and children, his estate be devoted to the erection of a hospital for incurables. His property was valued at $2,000,000.

Registering Scientific Men.—An effort is being made by *Science* to prepare a complete list of all those engaged in scientific investigation in the United States. All those engaged in original research, whether professionals or amateurs, are requested to send their names, addresses, and titles to the editor of *Science* in this city. Such a compilation as is proposed does not now exist, and it will no doubt be of considerable value.

A Congress of Hygiene has lately been held at Hamburg. The hygiene of hospitals, and of other buildings, public and private, was the principal subject of discussion.

Medical Societies of London.—London has seven large medical societies, all of which began their annual sessions in October. The names of these societies are: Obstetrical, Clinical, Hunterian, Medical, Pathological, Harveian, Medical and Chirurgical.

The Sulpho-Carbolate of Lime in Rickets.—Dr. D. Withers, in a paper read before the Ulster Medical Society (*Dublin Journal of Medical Science*), suggests the sulpho-carbolate of calcium as the best agent for getting lime into the system. The ordinary lime-salts are generally not very soluble or contain but a small proportion of the base. The sulpho-carbolate, however, is soluble in its own weight of water and each ounce contains ninety grains of calcium.

Health of Boston.—Bearing on the facts which we gave recently in regard to the increased mortality in this city from some diseases, are certain statistics regarding the health of Boston. It appears that there were nearly 800 more deaths in that city for the ten months of 1880 than during the corresponding time the previous year. This increase is attributed in part to the hot weather, and in part to the prevalence of diphtheria.

The Duration of Pregnancy, as estimated by Dr. Geo. J. Engelmann from the histories of six cases in which the date of fruitful coition was known, varied from 242 to 280 days, the average length being 264.6 days.—*Courier of Medicine.*

The Treatment of Brain Symptoms in Typhoid Fever, adopted by Dr. G. P. Atkinson, is to apply a blister to the epigastrium. This, he has found, almost always to quiet the delirium and relieve the patient.—*Brit. Med. Journal.*

Report of the Bureau of General Sanitary Science, Climatology, and Hygiene, to the American Institute of Homœopathy, Session of 1880. As the development of a scientific spirit among homœopaths means the inevitable extinction of its transcendentalism, we are glad to notice a document like the present one. In it we find the subject of quarantine in its various phases discussed intelligently and temperately. The article upon International Quarantine by Dr. Bushrod W. James gives a historical and critical review of the subject, and is particularly instructive. The other five articles upon National Quarantine, Quarantine for Refugees, Disinfection in Quarantine, the Cordon Sanitaire, and the Location and Sanitation of Quarantine Stations, show a good acquaintance with the questions involved, and are entirely devoid of any therapeutical peculiarities.

Saxolinum.—This is the title which, we are informed, the Committee of Revision and Publication of the Pharmacopœia of the U. S. of America have adopted as the official name for petroleum ointment. The term is derived from *saxum*, rock, and *oleum*, oil, and is quite expressive. It will be exactly defined as to properties, reactions, and melting point.

The Midwives in Cincinnati deliver 70 per cent. of the labor cases that occur in the city. The women are generally ignorant and uneducated. The *Cincinnati Lancet and Clinic* deplores the fact that they are allowed to practise so extensively. There is a law in that state which, if enforced, would put a stop to the abuse.

A Proposed New Law.—The Philadelphia County Medical Society have had a bill drafted for the purpose of making communications made to a physician in his professional capacity "privileged." The proposed law, which is similar to the one that has worked so well in this state, has been approved by most of the county societies and medical men of the state, and it will be presented to the legislature at its coming session.

The American Public Health Association will hold its Eighth Annual Meeting in New Orleans, commencing Tuesday, December 7, 1880, and ending Friday, December 10, 1880. Papers will be presented on Abattoirs, Epidemics, Life Insurance in its Relation to the Public Health; The Storm-water Question in City Sewerage; The Sanitary Engineering Problems of the Mississippi River; The Hygiene of Emigrant Ships; The Prevention of Venereal Diseases; Voluntary Sanitary Associations, etc. The special questions suggested for discussion at this meeting, in addition to those connected with the papers above referred to, relate to methods of preventing the spread within a town or city—after they have once been introduced—of such contagious or spreading diseases as diphtheria, scarlet fever, yellow fever, measles, small-pox, etc., and are as follows: 1. What are the best means of securing prompt and reliable information as to the presence and location of cases of such diseases? 2. What are the best means of securing isolation of the first or of single cases of such diseases, and what are the chief difficulties in securing such isolation? 3. Under what circumstances is it proper to declare such diseases epidemic in a place? 4. Under what circumstances is it proper to recommend the closure of schools on account of the prevalence of such diseases? 5. What precautions should be taken at the termination of each case as to—*a.* Care and disposal of the dead? *b.* Disinfection and cleansng of the room and house? *c.* Period of time at which it is safe to allow the convalescent to return to school or society? Brief practical papers upon any or all of these points are earnestly requested, and it is hoped that those attending the meetings will come prepared to give the results of their experience upon the questions, and to make positive recommendations. Gentlemen who propose to present papers at this meeting are respectfully requested to notify the President or Secretary of their intentions and of the title of their papers, in order that they may be assigned a proper place in the programme. By order of the Executive Committee, JOHN S. BILLINGS, M.D., *President*, E. H. JANES, M.D., *Secretary*.

ILLINOIS TRAINING SCHOOL FOR NURSES.—A Society has been formed in Chicago for the establishment of training schools for nurses. The movement is under the direction of many prominent citizens and will, undoubtedly, succeed in its object, that of securing competent and well-trained nurses for the state.—*Chicago Med. Rev.*

HOMŒOPATHY IN THE UNITED STATES.—From the report of the Bureau of Statistics made to the Amercan Institute of Homœopathy the present year, it appears that there are 6,000 homœopathic physicians registered in the United States. There are 23 State societies, of which 17 are incorporated by their repective States. There are 92 local or county societies, and 7 clubs, partly professional and partly social. Of the 38 homœopathic hospitals in this country 30 report 1,682 beds, which provided, in the last year, or 14,959 patients, with a mortality of 367—about 2½ per cent. The cost of building 25 of these hospitals has been $1,549,175, and they are mostly supported by contributions and paying patients. Of the 29 homœopathic dispensaries, 25 report having treated, in the last year, 117,564 patients, with 272,772 prescriptions, at a cost of $10,639.19, or about 4 cents or each prescription. Eleven homœopathic medical colleges are established, and instructed, last year, ,192 students, of whom 387 were graduated. The total number of graduates from these colleges is ,922. The cost of establishing 5 of these colleges has been $230,000; the cost of the others is not given. There are 16 homœopathic journals published in this country, quarterly, monthly, and semi-monthly. There are about 180 homœopaths in New York city, a less number (130) in Brooklyn, and nearly a thousand in the whole state. We have more in New York State than in all New England, where the number is between six and seven hundred. Boston has less than a hundred. Maine, New Hampshire, Vermont, and Rhode Island have between fifty and sixty, Connecticut twice that number.

In contrast to this, it is said that in Great Britain and Ireland there are not two hundred genuine homœopaths altogether. And the number is proportionately small in the continental countries. Homœopathy flourishes in Australia, however. It is a disease of new countries, and of a neurotic civilization.

BATTEY'S OPERATION FOR HYSTERIA.—A very instructive case, illustrating the peculiar efficacy of the above operation for hysteria, has been reported to the Berlin Medical Society. Dr. Israel presented to the society a young woman, aged twenty-three, cured of severe hysteria by "Battey's operation." The patient had suffered for some years with obstinate vomiting, accompanied by severe ovarian pains. She became extremely weak and anæmic. Many surgeons advised the operation, and she gradually arrived at the conviction that castration was the only remedy for her sad state. The operation was performed under chloroform, "with all antiseptic precautions." During the first three days after the operation there was extreme tenderness in the lower part of the abdomen, and ice had to be constantly applied. At the same time there was retention of urine, which only passed off at the end of twelve days. A week after the operation the vomiting had ceased, and the pain in the ovarian region had disappeared. The patient's cure remained permanent. One detail, however, of this beautiful illustration of the value of oöphorectomy remains to be mentioned, and it is not an unimportant one. The operation was a pretended one—a superficial wound was only made!

A case somewhat *à propos* to this has recently been reported in a French journal. It was that of a woman, aged forty-three, who was suffering from an ovarian tumor. The tumor was removed, and the ovary of course with it. The woman got well of the operation, but became permanently maniacal. The mania could not be attributed to anything except the operation.

LIFE AND MIND ON THE BASIS OF MODERN MEDICINE.—The editor of the *Lancet* makes this comment in criticizing a letter upon the above subject: "We maintain that the non-existence of a something beyond or behind matter cannot, with our present knowledge, be proved. The statement, that function or motor force is imminent in matter is not sufficient in these days of vigorous analysis, as an explanation of the meaning of energy in organized bodies present in the state called life, and absent in death. Co-ordinated or associated action surely has a higher or deeper signification than can be predicted of corpuscular *vis insita*. This can never account for the intelligent co-operation of atoms in working out harmoniously the well-being of the individual organism."

NEW YORK PHYSICIANS' MUTUAL AID ASSOCIATION.—The twelfth annual meeting of the New York Physician's Mutual Aid Association was held November 11th, at the Academy of Medicine. The retiring President, Dr. Mark Blumenthal, who has served for the last six years, read the annual report of the Board of Trustees, from which it appears that the Association now numbers three hundred and fifty members; that its permanent fund has increased from $3,000 in 1875 to over $6,250 in 1880, mainly due to the liberal contributions of Dr. Abram DuBois and Dr. A. F. Sterling, of this city. The benefits of the Association are perhaps best shown by the fact that it has distributed over $12,000 during the last six years, and, since its organization in 1868, over $20,700 among the heirs of its deceased members. The following officers were elected: *President*, Dr. Robert A. Barry; 1st *Vice-President*, Dr. W. W. Reese; 2d *Vice-President*, Dr. Geo. A. Peters; *Recording Secretary*, Dr. David Magie; *Assistant Secretary*, Dr. Daniel Lewis; *Corresponding Secretary*, Dr. J. H. Anderson; *Treasurer*, Dr. Robert Campbell; *Trustees* to serve for three years, Drs. Mark Blumenthal, Erskine Mason, and Geo. G. Wheelock.

ANIMALS WITH A SECOND BRAIN IN THE SPINAL CORD.—The fall meeting of the National Academy of Sciences, which took place in this city last week, was devoted almost entirely to the physical sciences. At the closing session, however, Professor Marsh read a paper on the "Dimensions of the Brain and

Spinal Cord in some Extinct Reptiles," which contained some very interesting facts. Professor Marsh first brought the evidence to sustain his proposition that the older the type of mammal, reptile, or fish, the smaller the brain. He then called attention to a very curious development, in certain fossils, near the sacral region of the cord. In a gigantic reptile of the jurassic formation, an animal nearly thirty feet in length, the brain was scarcely as large as that of an ordinary dog, judged by the size of the cranial cavity. But the spinal canal presented the extraordinary feature of an immense enlargement in the sacral region, where the bone was so excavated as to form an immense vaulted receptacle, several times larger than the brain cavity. The sacrum consisted of four vertebræ, which were well ossified and of great solidity, and within this was contained, during the life of the animal, a posterior brain—if he might use the term—which was eight times as large as the encephalon. The point was of very curious interest, not only as a fact of fossil anatomy, but in respect to the physiological inferences that might be drawn from it, into which he did not propose to enter. It was so remarkable, indeed, that he took occasion to examine other examples of the same species before accepting it as a general fact of extensive application. Upon recurring to some younger specimens of the same gigantic saurian, he was enabled to verify the existence of the cavity in every instance, and to prove that sacral enlargement of the cord in extinct reptilians was an extraordinary fact. If it had appeared in a single instance, it must, of course, have been regarded as a phenomenon due to injury or disease; but in all cases, since his attention was attracted to the point by this enormous creature, he had found the posterior cavity in extinct reptiles.

There was nothing analogous to this sarial enlargement, Prof. Marsh continued, in existing vertebrates. The aurphiax had absolutely no brain—that is, no cerebral enlargement of the cord at the anterior extremity, but there was no enlargement of the spinal cavity at the sacrum which answered to what he had observed in extinct species.

In answer to an inquiry whether the sacral enlargement was in such a position as to furnish a point of origin for the nerves of the leg, Prof. Marsh said that such was the case, and that the animal had very powerful hind legs; but the fore legs were equally strong, and there was no corresponding enlargement.

RESURRECTIONISTS IN BALTIMORE.—Much ado has been recently made in Baltimore over the stealing of two bodies from the Baltimore Cemetery. The robbers had not at date of writing been discovered, but it is stated to be certain that no medical colleges had any connection with the matter.

THE TWENTY-FIFTH ANNIVERSARY OF THE WOMAN'S HOSPITAL was held at the hospital building on the afternoon of November 18th. The annual reports were read, showing that 5,397 patients had been treated since the foundation of the hospital. Additional accommodations were needed for the treatment of the patients, of whom there were at the time 105 in the hospital. Speeches were made by Rev. Dr. Potter and by Dr. R. F. Weir.

THE DIPHTHERIA EPIDEMIC IN BROOKLYN.—During the week ending Saturday, November 13th, there were 139 cases of diphtheria reported to the Brooklyn Health Board, of which number 47 proved fatal. In the week previous there were 109 cases, and 57 deaths; while in the week ending October 30th, 46 deaths from diphtheria were reported.

The disease is scattered over various sections of the city, but during the past three weeks it has been most prevalent in the Fifth, Tenth, Eleventh, and Twenty-fifth Wards. The highest rate of deaths attained in any ward was in the Tenth, were there were seven fatal cases in one week. The Register of Vital Statistics thinks that the climax of the disease has been reached.

MEETING OF THE SANITARY REFORM SOCIETY.—The New York Sanitary Reform Society held its annual meeting at the Society's headquarters, No. 79 Fourth Avenue, on the evening of November 18th. Chief Justice Charles P. Daly presided. A large number of prominent medical men and laymen were present The President, James Gallatin, read the annual report The work laid out for the Society during the coming year was, he said, to secure a law extending the supervision of the Health Board over the plumbing in all houses, whether tenements or otherwise, to endeavor to suppress the Hunter's Point nuisances to compel the licensing of milk venders, to educate the poor in sanitary measures, and to advocate a radical change in the present plan of cleaning the streets.

Prof. C. F. Chandler delivered an address upon the recent work of the Board of Health, devoting himself especially to a review of the good effects o the present tenement-house laws. He showed tha since the passage of the law, procured by the efforts of the Society, 1,047 tenement-houses have been erected in this city. These accommodate 7,736 families, aggregating about 23,000 persons. By reason of the new law, these 23,000 persons have been provided with the best kind of house shelter, and all in a little over a year. The law has served to educate the architects, so that now fully one-third of the tenement plans presented to the board for approva are accepted without requiring a change. Prof Chandler said one of the most important results o the improved law was the fact that not a tenement house has been built since the law was passed in which air and light were not given to every singl room occupied as a living or sleeping room. In conclusion, the Professor discussed the steady decreas in the rate of infant mortality in the city, and then urged that a radical change should be made in th present system of street-cleaning, and advocated th adoption of the "block system" of cleaning, as urged by him before the Senate Committee on Cities som time ago.

The meeting was an interesting and successful on in every respect.

CARTWRIGHT LECTURES,*

ON THE

PHYSIOLOGICAL ANTAGONISM BETWEEN MEDICINES, AND BETWEEN REMEDIES AND DISEASES.

By ROBERTS BARTHOLOW, M.D.,

PROFESSOR OF MATERIA MEDICA AND THERAPEUTICS IN THE JEFFERSON MEDICAL COLLEGE, PHILADELPHIA.

(Special report for THE MEDICAL RECORD.)

LECTURE III.

ANTAGONISM OF ATROPIA AND PHYSOSTIGMA—ATROPIA AND PILOCARPINE—ATROPIA AND MUSCARIA—ATROPIA AND QUINIA—ATROPIA AND BROMAL HYDRATE, AND ATROPIA AND ACONITINE.

Mr. President and Gentlemen:

The next investigation concerning the antagonism between medicines to which I invite your attention is that relative to the action of atropia and physostigma, or Calabar bean. In the experiments made in this connection, both the extract and the active principle of the drug, eserin, have been employed to produce the physiological effects of physostigma. For the first time, in 1864, a case of poisoning by atropia was treated by Kleinwachter with the internal administration of the latter, which had the effect of relieving the symptoms to a certain extent. In 1867 Bourneville, in a treatise on the treatment of tetanus by physostigma, recorded a single experiment exhibiting the opposed action of this agent and atropia. In 1868 I made a number of experiments, whose results were similar, and, in 1869, followed the researches of Prof. Thomas R. Frazer, of Edinburgh, which were the most important which had been made up to that time. Next came the report of the special committee appointed by the British Medical Association, of which Dr. J. Hughes Bennett was the chairman.

In order to comprehend the extent and character of the antagonism between the two agents, it is necessary that we should form a definite conception of the action of each. In what respects do they agree, and in what differ in their effects? The effects of atropia have already been sufficiently studied, and therefore need not be recapitulated. Physostigma, unlike atropia, does not affect the cerebral functions. It contracts the pupil, paralyzes the voluntary muscles without interfering with sensibility, increases secretion, augments the heart's action and the arterial tension, and causes death by paralyzing the respiratory muscles. While, therefore, atropia occasions active delirium, with hallucinations and illusions, by its effect upon the brain, physostigma does not affect this organ at all. As regards the pupil, atropia causes dilatation by stimulating the radiating fibres innervated by the sympathetic, and physostigma paralyzes these fibres. Atropia quickens the respiratory movements by its stimulating action, and physostigma paralyzes the muscles of respiration. Atropia increases the rate of movement of the heart, without increasing its power, and physostigma increases its power without adding to the rapidity of movement. Atropia diminishes the salivary and intestinal secretions, and physostigma increases these. Finally, they differ in their action on the voluntary muscular system, atropia paralyzing the motor nerves, and physostigma causing spinal paralysis.

In regard to the lethal effects, Professor Frazer says: "Atropia prevents the fatal effects of a lethal dose of physostigma by so influencing the functions of certain structures as to prevent such modifications from being produced in them by physostigma as would result in death. The one substance counteracts the action of the other, and the result is a physiological antagonism so remarkable and decided that the fatal effects, even of three and a half times the minimum lethal dose of physostigma, may be prevented by atropia." The first case reported of the treatment of poisoning by atropia with physostigma was successful, and the first experiment made for the purpose of testing the antagonistic action of the two also proved a success.

The first extended and complete series of experiments on the subject, however, were made by myself in the year 1868, as mentioned previously, before the appearance of the account of Bourneville's observation in the same year, and the results of these were published in my prize essay of the American Medical Association in 1869. I respectfully submit, therefore, that I have a priority of a whole year over Frazer, although I do not hesitate for a moment to acknowledge the superiority of his researches. In his historical review I think he hardly does me justice, for when he quotes from my essay he merely takes a sentence or two from the general conclusions which do not give a satisfactory idea of the whole meaning of my researches. Yet, as I shall presently show, subsequent investigations have confirmed my conclusions, which were as follows:

"Atropia and physostigma are antagonistic as to their influence over the respiratory movements—atropia increasing, and physostigma retarding them.

"They are antagonistic in their action on the heart—atropia producing excitation of the cardiac ganglia, and physostigma paralyzing them.

"They are opposed in respect to their action on the sympathetic—atropia causing increased action, and physostigma paralyzing this system.

"They have opposite effects on the pupil, in virtue of opposite effects on the sympathetic—atropia dilating the pupil by its action on the radiating fibres of the iris, and physostigma contracting the pupil by paralyzing the radiating fibres."

Frazer was convinced, by his extended and careful researches, that the lethal effects of atropia and physostigma were antagonistic throughout a wide range; but the committee of the British Medical Association, while admitting the existence of the antagonism, arrived at the conclusion that it was much more limited in its range than Frazer believed.

The special points of the antagonism between the two agents have now been studied with great care by a number of observers. As regards the heart, physostigma first causes an increase in the blood-pressure, but afterward a diminution of the same, while the action of the heart remains accelerated. It slows the heart by lengthening the diastolic pause, augments the force of the contraction, and increases the arterial tension. (After alluding to the experiments of Arnstein and Sustschinsky, Rossbach and Fröhlich, Harnach and Witkowski, Köhler, Laschkewich, and others, the lecturer went on to say): How much soever the various observers may differ in their explanations, the fact remains that atropia and physostigma are opposed in their action as regards the heart.

---

* Of the Alumni Association of the College of Physicians and Surgeons, New York.

In regard to their effect on respiration, there are fewer differences of opinion. It is generally conceded that atropia stimulates the respiratory centre, while physostigma tends to suspend reflex excitability, and is a spinal paralyzer; so that the function of respiration is early affected when it is given.

The point of opposition which is most conspicuous, and that which first attracted attention to the antagonism between the two, is their action upon the pupil—eserine producing contraction, and atropia dilatation. There are great differences of opinion in regard to the mechanism of these two opposed actions. By some the contraction of the pupil by eserine is believed to be due to a paralyzing effect on the dilator fibres, and by others to a spasm of the sphincter fibres. The latter view would seem to be correct from the fact that the effect of physostigma on the muscular coat of the intestines is to bring on tetanic contraction or spasm. When the pupil is contracted by eserine, it can readily be dilated by the employment of atropia; but when it is dilated by the latter, eserine has no effect in causing its contraction.

The delirium, hallucinations, and other cerebral phenomena caused by atropia are in no wise affected by physostigma. In cases of poisoning by the latter the mind remains unaffected until toward the close of life, when carbonic-acid narcosis comes on. This, indeed, occurs under the toxic effect of all purely respiratory poisons, and is due simply to the suspension of hæmatosis. Now carbonic-acid narcosis being one of the prominent effects of atropia-poisoning also, physostigma and atropia cannot be said to be antagonistic in their action on the cerebrum.

In their spinal effects there are obvious differences between the two agents. It is true that they are both paralyzers; but atropia gives rise to an after-tetanic condition in the cold-blooded animals. When they are given together, this tetanic condition occurs at once (a fact that I was the first to demonstrate), and so exalted is the reflex function of the spinal cord that a tetanic spasm is excited by a slight tap upon the surface of the body; the condition between being one of relaxation. In several of the cases of atropia-poisoning trismus was quite a marked symptom. The paralysis occasioned by atropia, as Ringer and others have shown, is largely spinal, although the irritability of the motor nerve-trunks is impaired. Dr. Mary Putnam-Jacobi's experiments show that atropia impairs the sensibility of the sensory nerves. Physostigma, on the contrary, augments their sensibility, and is a spinal paralyzer; while the motor nerves and muscles remain unaffected by it. These agents, therefore, agree in more points than they differ in their action on the spinal cord.

In their effects upon secretion, however, we find greater differences. An increase of the flow of saliva, tears, sweat, and the secretions of the intestinal glands is a constant result of the action of physostigma, and this is due, according to Haidenhain, to its general stimulating effect upon the secretory nerves. This conclusion is apparently confirmed by the fact that when the *chorda tympani* nerve is divided near the submaxillary gland, no increased flow of saliva takes place. As is well known, the action of atropia is the opposite of this. It suspends secretion, most probably by paralyzing the end organs of the nerves in the gland. Thus, Schiff has demonstrated that when the *chorda tympani* nerve is divided, secretion of the submaxillary gland is arrested.

Physostigma and atropia also act differently upon the motor functions and the muscles. I have already laid stress upon the tetanic effect produced by atropia in the cold-blooded animals, and the fact that trismus occurs in many of the cases of atropia-poisoning. Botkin pointed out that atropia paralyzed the motor nerve-trunks, while Laschkewich and Frazer have shown that neither these nor the muscles are affected by physostigma. Though differing in their action on the motor functions and muscles, therefore, they are not opposed.

Our conclusions from a study of the subject may be summed up as follows:

First.—Physostigma, or eserine, and atropia are antagonistic in their action on the pupil.

Second.—They are different, but probably not antagonistic in their action on the heart.

Third.—They are opposed in their effect upon the respiratory function; physostigma paralyzing, and atropia stimulating it.

Fourth.—They are not opposed in their action on the cerebrum. Atropia produces delirium and hallucinations, while physostigma does not affect the cerebral functions; but both cause more or less carbonic-acid narcosis.

Fifth.—They act differently, but not antagonistically on the spinal cord and nerves. Both cause paralysis; but while atropia impairs the irritability of the motor nerves, physostigma does not. Physostigma increases the irritability of the sensory nerves; while atropia, if it has any effect at all upon them, diminishes this.

Sixth.—They are antagonistic in their action on secretion; physostigma stimulating it and atropia arresting it.

From the above conclusions it follows that atropia overcomes the lethal effects of physostigma by stimulating the respiratory function; but it is certainly very doubtful whether physostigma is of any practical service in poisoning by atropia.

BELLADONNA AND PILOCARPINE.

The opposed action of these two agents constitutes one of the most interesting and complete in the whole series of medicinal antagonisms. Having sufficiently studied the physiological action of atropia, we must now inquire what is that of pilocarpine. The history of jaborandi affords an admirable illustration of the achievements of modern physiological and therapeutical research. When it was first introduced, great numbers of observers all over the world set about the investigation of its action and effects. The results of their first researches have been abundantly confirmed by subsequent observations, and the literature of the subject is already vast.

In a few minutes after a dose of pilocarpine has been taken into the stomach, or hypodermically injected, the action of the heart is increased, a feeling of warmth goes through the system, and the face becomes flushed. When a very large amount is taken, this increased action of the heart does not occur, and in the smaller doses it does not continue after the sweating commences. The pupil becomes contracted, spasm of the accommodation takes place, and recession of the near point results. There is more or less cephalalgia and feeling of tension about the head, ordinarily accompanied by transient vertigo. Soon after these symptoms are noticed the perspiration begins, and quickly becomes excessive, the skin literally pouring out water. Simultaneously, or even before the sweating, the saliva commences to flow also in enormous quantities, so that it can often be measured by pints. In some instances, however, the one secretion seems to be substituted for the other, though usually both are excessively increased. When the sweat and saliva have thus become profuse, the pulse declines in force, volume, and quickness, the face grows pale, and a sense of exhaustion ensues. The temperature, which may perhaps ascend above the normal at first, now falls somewhat below it, and a feeling of chilliness is experienced. The secretion of urine is less than normal, but the bladder is very irritable. Drowsiness comes on as a result of exhaustion, and not in consequence of the direct effect upon the brain. When the agent is taken into the stomach, more or less nausea and vomiting are usually produced, but are much less marked if it is injected under the skin. Sometimes a watery diarrhœa is also one of the results.

(The lecturer now proceeded to indicate the main points of antagonism between atropia and pilocarpine, after which he alluded to two cases of belladonna-poisoning treated by Ringer, with the subcutaneous injection of pilocarpine, without appreciable result. He then went on to detail the results of the experiments made for the purpose of testing the antagonism by Vulpian, Langly, Marmé, Petrina, Nowroski, Robin, himself, and other observers, and arrived at the following conclusions :

First.—Belladonna and pilocarpus are antagonistic in their action upon the secretions, especially of saliva and sweat, pilocarpus stimulating these enormously, and belladonna arresting them.

Second.—They are antagonistic in their action on the heart and the arterial system, pilocarpus slowing and weakening the heart, and lowering the vascular tonus, and belladonna strengthening and accelerating the movements of the heart, and increasing the arterial tension.

Third.—They are antagonistic in their action on the eye, pilocarpus producing contraction of the pupil, spasm of the accommodation, and recession of the near point of vision, and belladonna dilating the pupil, paralyzing accommodation, and inducing presbyopia.

Fourth.—As regards the brain, there is no real antagonism between the two. The excitement, delirium, and hallucinations caused by atropia remain unaffected by pilocarpine, while the soporose condition induced by the latter is due merely to exhaustion and cerebral anæmia, and not to any primary effect upon the brain.

Belladonna and pilocarpus agree in the unsusceptibility of children to their action. Ringer and Gould found that a quantity of jaborandi which would excite profuse perspiration in adults had little or no effect upon children ; and it has been equally well proved that children are much less susceptible than adults to the effects of belladonna.

We have next to consider the mutual counteractions of

ATROPIA AND MUSCARIA.

Muscaria is obtained from *amanita muscaria* (the fly-fungus). Muscaria or muscarine has strong alkaline and basic properties, and unites with acids to form salts. It is a colorless substance, of the consistence of syrup, is readily soluble in water, and its salts rapidly deliquesce on exposure to the air. It seems to be a very active toxic agent, one-thirtieth of a grain producing marked symptoms in the human subject. The general effects are as follows : considerable gastro-intestinal disturbance is caused by it, consisting of nausea, vomiting, diarrhœa, and severe colic, which are due to the tetanic contraction of the muscular layer of the bowel which it produces, and an active delirium characterized by rambling incoherence and a somewhat pleasurable excitement resembling the effects of alcoholic intoxication. During the stage of delirium the pupil is contracted, and the vision is dim, blurred, and probably double.

In toxic doses the agent produces epileptiform seizures, trismus, loss of reflex irritability, and coma, more or less profound, after the period of intoxication. The action of the heart is enfeebled and finally arrested in the diastole ; the respiration is labored and stertorous ; the secretion of the salivary glands is increased ; the surface of the body grows cold, and death takes place from failure of the heart. On the brain it probably acts in two ways : first, stimulating the cells of the gray matter, and then paralyzing them, the organ being in a state of anæmia, on account of the enfeebling effect of the agent upon the heart. On the eye it causes spasm of the accommodation and marked myosis by stimulating the *motor oculi*. The secretions, and especially the salivary, are increased by muscaria, and, according to Prévost, the bile, the pancreatic and the urinary secretions are stimulated by it, an effect which is probably due to the action of the drug upon the end organs of the nerves. The cardiac movements are at first slightly accelerated, and shortly afterward retarded by it, and a marked decline in the blood-pressure is an invariable result, after a short preliminary increase in it. Muscaria would seem to act on the motor ganglia of the substance of the heart, and not on the muscle or the inhibitory apparatus. The respiration is quickened during the stage of excitement, but is afterward retarded and rendered shallower by the paralyzing effect of the agent upon the respiratory centres.

No antagonism could well be more exact than that between muscaria and atropia. As regards the brain, the intoxication with cerebral anæmia caused by the former is opposed by the delirium and cerebral hyperæmia resulting from the latter. The contraction of the pupil caused by muscaria, by its stimulating effect upon the circular fibres, is opposed by the dilating influence of atropia, due to its stimulating action on the radiating fibres. The effect of atropia is relatively more powerful, however ; for when the pupil is dilated by the action of the latter, it cannot be forced to contract by the use of muscaria. The salivary secretion is increased by muscaria, which stimulates the end organs of the nerves in the glands, while it is arrested by atropia, which paralyzes these nerves. The antagonism is very striking in regard to the heart, as I mentioned in my first lecture ; for if the organ is arrested in diastole by muscaria, it is started again by atropia. Not less marked is their opposed action on the respiratory function ; muscaria gradually rendering the respiration less and less frequent and deep, and finally arresting it, while atropia stimulates it.

I next call your attention briefly to the antagonism between

ATROPIA AND QUINIA.

Pantelejeff, who made the only systematic series of experimental investigations concerning the opposed action of these agents, has found that quinia arrests the heart in diastole, and the subsequent use of atropia causes it to resume its action. This result he observed both in rabbits and frogs. There is abundant clinical experience in regard to this antagonism, but this does not concern our present purpose. He also ascertained that contraction of the arterioles was caused by the injection of quinia, and dilatation by that of atropia, and that quinia caused a rise in the blood-pressure after a brief preliminary fall, while atropia retarded it. (The lecturer, after speaking briefly of the antagonisms between atropia and bromal hydrate, and between atropia and aconite, concluded as follows:)

One of the triumphs of modern organic chemistry is the reconstruction by synthesis of organic alkaloids, the physiological demonstration confirming very strikingly the accuracy of chemical methods; and not less interesting is the demonstration that apparently different alkaloid principles obtained from different sources are the same. Thus atropia, daturia, and hyoscyamia are all found to be identical in chemical composition. The new mydriatic duboisia, with the exception of its more prompt and transient effect upon the pupil, its less irritating action on the conjunctiva, its less deliriant and greater hypnotic power, appears to have just the same physiological effects as atropia, and the late researches of Ladenburg seem to prove that it is identical with hyoscyamia. Throughout the whole range of the antagonisms of atropia, duboisia might be substituted for the latter, and the facts true of atropia are likewise applicable to duboisia and to hyoscyamia. Special researches have been made in regard to the antagonisms of duboisia, and thus in a short time after its introduction to professional notice this agent is as fully understood in respect to its powers and uses as belladonna after centuries; but the one is studied by the modern physiological method, and the other, coming down with vague traditions and baseless theories, is only properly understood at last when the progress of physiological research enables new investigations to conduct to right conclusions.

Original Communications.

EXTENSION AND A NEW METHOD FOR ITS PRODUCTION.

By CHARLES F. STILLMAN, M.D.,

NEW YORK.

The subject of extension is one of vital importance to surgeons, since upon its correct understanding and application depends the arrest of inflammatory processes in joints. At present the profession is divided as to the necessity of extension, its opponents embracing many of our most eminent authorities, and its advocates being also numerous and influential.

I propose in this paper to touch as briefly as possible upon some of the more important features of the subject, defining the true significance of extension, stating the reasons why each of the systems at present used for its production are not universal in application, and advocating a new system founded upon heretofore unrecognized principles and applicable to every joint.

Rest is universally conceded to be the chief desideratum in the curative treatment of inflammatory conditions of joints, but *complete rest of a joint is never obtained during life without the employment of a correct extending apparatus.* The most perfect type of a joint in a state of rest is the joint of a corpse, or, in other words, a dead joint. This is mobile and relaxed. Now, what factors have been eliminated by death to produce this condition of rest? These are:

1. The disappearance of contractile power in the muscles governing the joint, and
2. Relief from superincumbent weight.

Every joint of the body is so constructed that the muscles governing that joint have their origin above and their insertion below it, and these muscles possess a persistent opposition to one another which must be exactly balanced or distortion occurs. The contractile power of these muscles is therefore constantly striving to keep the balance of power exactly even in every posture of the body, and as this is involuntary, it cannot be subdued, so long as functional life exists in a muscle, without the use of an extending appliance.

The joint of a corpse after cessation of the rigor mortis is already in a state of extension, as both the weight of the body and the contractility of the muscular fibres have ceased to be factors in holding the articular surfaces together, which are only prevented from falling apart by the ligamentous and non-contractile structures.

Therefore the numerous experiments which have been made to demonstrate that extension cannot exist, and which have invariably been made upon the dead body, are entirely unreliable, as the joints were already in a state of extension, *i.e.*, of complete rest or relaxation, and beyond this the inherent ligamentous strength of the joint does not readily allow of stretching, if it indeed would not prove to be positively injurious, by interference with the ligamentous structures and supports of the joint. The amount of extension then, which any extension or stretching apparatus should allow, is just sufficient to produce the relaxed condition found in the dead joint and no more.

It is certainly impossible to obtain even a minute separation of the contiguous articular surfaces unless this muscular contractility be first overcome. When this is done, the relaxation which follows prevents the opposing surfaces from being jammed too closely together, and allows a scarcely perceptible separation of the surfaces of a joint; but the extent of this is wholly dependent upon the inherent strength of the non-contractile structures of the joint.

It is not, then, as many of our leading surgeons suppose, and which has brought the practice of extension into such disrepute, the bones or ligaments of a joint which we should attempt to extend. The bones cannot be pulled apart more than they are in a dead joint by any extending power we ought to use, unless the ligaments are in badly diseased condition, and to do so then is "bad practice."

This function which the muscles possess of keeping the joint-surfaces closely in contact at any angle during health is abnormally increased in inflammatory conditions in direct proportion to the acuteness of the process.

Suppose, for instance, the articular surfaces from some exciting cause become irritated, and effusion takes place. By this effusion the individual fibres of the muscles are put still more upon the stretch, and in consequence the contractile force of the muscles is involuntarily excited to press the opposing articular surfaces still closer together.

As a result of the increased irritation we have still further effusion, with its involuntary reflex muscular contractions (which fix the joint rigidly), and injury to the articular surfaces, and finally, implication of surrounding tissues.

Therefore, in order to overcome this primary irritation of the joint, we must overcome the contractility of the muscles governing the joint, and also relieve it from weight, in other words—place it in the relaxed condition of a dead joint.

There is one more feature of a dead joint whose importance we have failed to recognize in treating inflammatory condition, and that is its *mobility*. When effusion takes place—for instance, in an acutely inflamed knee—the limb immediately begins to flex in proportion to the acuteness of the attack and amount of effusion, as in this position the balance of power is most easily maintained. But this flexion is graduated by the course of the inflammatory process, and it varies constantly, according to the ever-varying amount of effusion in and about the joint—its period of increase corresponding to the increase of effusion, and its period of decrease corresponding to the decrease. It is then in a state of constant variation.

We have already noted the fixation of the limb as a consequence of the contractile irritation of the muscles induced by inflammatory action—but this fixation continues through all the degrees of flexion, acting as a protector for the joint, with especial power to prevent lateral deviation from the vertical axis—and, therefore, if by an extending appliance we subdue the contractility of the muscles we must have it so arranged as to produce this lateral protection for the joint which ceases with the muscular contractility.

Our model extension splint should then combine among its qualifications the power to:

1. Overcome contractility of the muscles.
2. Relieve superincumbent weight.
3. Afford support to the joint at every angle the limb may take, adapting itself automatically to all degrees of flexion.
4. Allow any degree of flexion, in other words, it should provide a false joint which would perform the functions of the affected one, and give it absolute *rest* by producing a symmetrical extension of the muscles which govern it.

We have already stated that the surgical profession is now divided on the question of extension—one party opposing its practice, and the other advocating it. The former try to produce rest by encasing the joint in a splint which will fix it immovably in a desired position, and prevent the movements due to irregular contraction of any one set of muscles in its efforts to preserve a balance of power.

This plan of treatment is insufficient, since the inherent contractility of the various muscles is not reduced to a degree in which the articular surfaces are prevented from pressing strongly against each other, and no motion is allowed. The more efficacious of these splints are made of plaster-of-Paris, felt, and allied substances, which adapt themselves perfectly to the form of the limb, and yet are rigid and unyielding.

Some surgeons also try to produce rest for a joint by having the supine position assumed.

This, alone, is not sufficient, because:

1. The contractile force of the muscles is aroused by irritation in a joint, and if there be no properly devised and applied extending power to overcome this, the inflammatory process is destined to increase.
2. The supine position relieves superincumbent weight, but does not reduce the contractility which is the chief factor to be subdued.
3. The general health is apt to suffer.

The advocates of extension have heretofore chosen methods for producing it which may be classified under *three* different systems, which I will here briefly describe, and will also detail a *fourth*, which presents many new points for consideration.

These systems are known respectively as "Hutchison's method," "Buck's extension," and the "long splint."

Let us glance at their most important features.

The practice of swinging the affected limb (see Fig. 1) is one of very ancient date, and is again coming into prominent notice through the advocacy of Prof. Hutchison of Brooklyn. Bearing in mind the two main features to be overcome, viz., the persistent contractility of the muscles and the superincumbent weight, it will readily be seen that to combat these we have but one factor—the weight of the part below the joint—and even this ceases when the body assumes a supine position.

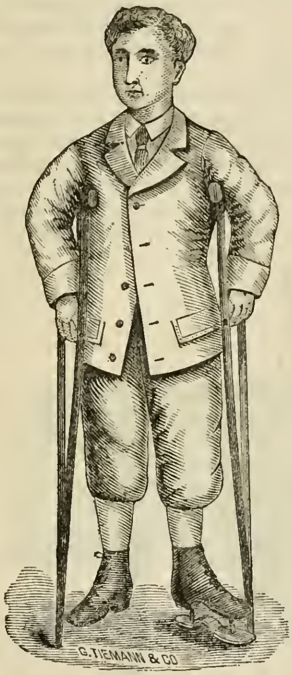

Fig. 1.

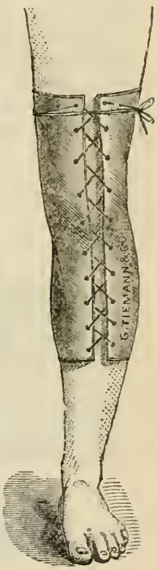

Fig. 2.

The superincumbent weight is to a great extent taken off (from a knee- or hip-joint, for instance), in the swinging or Hutchison's method, by the use of crutches, but the contractility of the powerful muscles which control either of these joints is but little affected by the weight of the part below it, for it is the natural function of these muscles to lift and swing the part below. Then, too, since the contractility is not subdued, the opposing inflamed articular surfaces are not prevented from being jammed together, producing the reflex train of symptoms already described, and in less acute cases does not prevent pain and involuntary startings.

Then, again, the lateral mobility allowed by this system is harmful unless the contractility be first overcome, and to remedy this, splints are moulded upon the joint (see Fig. 2), but these afford support only in the position in which they are placed, and do not admit of variable flexion, which is of great importance to the proper restoration of function.

Hutchison's method, then, does not produce complete rest for a joint, because: 1st, it fails to control the persistent muscular contractility, and therefore fails to prevent the opposing surface from being jammed together; 2d, it does not allow flexion; 3d, it only partially relieves superincumbent weight.

Its advantages are, that its partially relieved superincumbent weight supports the joints in any given position, and does not confine to bed.

Another system, which has been generally recognized as being of great value, is known as "Buck's," from its prominent advocacy and introduction by the late Dr. Gurdon Buck, of New York. It consists in the suspension of weights from a limb, the counter-extension being produced by placing the body upon an inclined plane, or attaching a perineal band to the headboard by a cord (see Fig. 3). It acts as an extender by increasing to a great degree the amount of weight below an affected joint, the natural amount of weight being, as we have seen, controlled by the contractility of the muscles.

It produces extension and combats this contractility certainly, but it does so by impairing the entire muscular structure of the limb, for by placing this upon a prolonged stretch, the muscles lose in contractile power, not only those governing the affected joint, but also those governing other joints in the limb. Added to this the patient is obliged to lie in bed to the great detriment of the general health. Then again, as effusion in a joint increases, the limb must flex or severe suffering be induced. It is not physiological, therefore, to retard this flexion which the extra weight upon the part below would be likely to do.

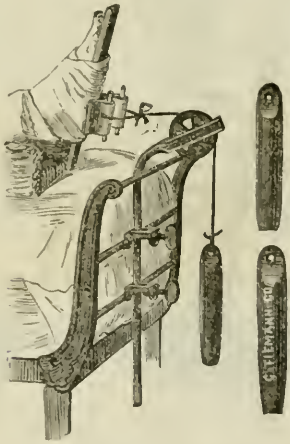

FIG. 3.

Buck's system, then, does reduce the contractility of the muscles, and relieve superincumbent weight; but while not entirely preventing, it tends to limit flexion.

Therefore among its disadvantages may be enumerated: 1st, limited flexion; 2d, confinement to bed; 3d, application confined to a few joints; 4th, necessity of a perineal band; 5th, lack of lateral support; 6th, extension affects the entire limb, and is not confined alone to the affected joint.

A third form of extension appliance is the "long splint," or straight extension splint, which is fixed to the foot below and the hip above, with the help of a perineal band, the extension being produced by a ratchet, located between these points, which forces the extremities further apart (see Fig. 4).

This causes extension in the straight position, but is open to the same objection as "Buck's," viz., that it extends the entire muscular system of the limb, and has the additional fault of not producing it in the vertical line, the foot being thrown inward in proportion as the extension power is exerted.

It relieves superincumbent weight, and possesses the advantage over "Buck's" of not confining the patient to bed. It is, however, inferior to it in the fact that it entirely prevents flexion, and thus tends to produce anchylosis by causing prolonged fixation in a straight position.

One of the reasons why a straight extension apparatus is of little use in subduing inflammatory conditions attended with swelling or effusion, is because the extension power is not exerted in the axes of the limb at right angles to the transverse muscular fibres; for as the joint begins to fill, the limb begins to flex, and, taking the knee for example, the extension is not directed in the proper axes of thigh and leg.

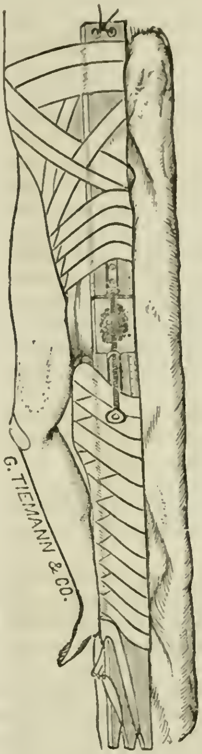

FIG. 4.

Then again, unless the limb can be put in a straight position, the splint cannot be applied, so that its range of application is limited.

In enumerating the disadvantages, then, of the long splint as a method of extension, we may include: 1st, extension in only the straight position; 2d, extension of the entire muscular system of the limb; 3d, extension not produced in the vertical line; 4th, prevention of flexion; 6th, oblique attachment to the entire muscular system of the limb by adhesive plaster; 7th, necessity of a perineal band; 8th, application confined to few joints.

Its advantages are, that it, 1st, relieves superincumbent weight; 2d, produces extension in a straight position of the limb; 3d, affords lateral support to the joint; 4th, does not confine to bed.

The long splint embodies the principle, variously modified, upon which are based the forms of apparatus now most in use for direct extension in cases of joint diseases. Its many modifications bear the names of their advocates, and while in this article we avoid a discussion of their individual merits, we must remember that one leading feature has been frequently enunciated, *i.e.*, that they produce extension by effecting a separation between the bones of a joint. Now, the writer of this article believes and has endeavored to demonstrate that extension means prevention of opposing surfaces from being jammed into immediate contact, thus producing the state of rest found in a dead joint, and that so long as pressure is thus removed, it is not necessary to forcibly separate articular surfaces, and a glance at any of our instrument catalogues will show that only those splints have survived the test of experience and come into general use which are attached to the muscles governing the affected joint, throughout their entire length, by adhesive plaster, and all those appliances attached only at the foot and hip have been discarded.

The method of extension which it is one of the aims of this paper to lay before the profession is based upon the proposition that we should endeavor to effect a complete reduction of the contractility of muscles affecting the inflamed joint without diminishing their vitality, relieve superincumbent weight, and yet allow all necessary motion.

This can only be produced by an extension splint which adapts itself to every angle the limb may take, and so firmly and rigidly attached just above and below the joint that, by counter-pressure against the bulk of muscles above the joint, the fibres between the two attachments are forced to lie in a relaxed condition, thus affording the joint rest by transferring to the extension splint the task of combating the contractile tension of the muscles and bearing the superincumbent weight.

This counter-pressure is effected by pushing the muscular mass away from the joint by the segment of a hollow rigid cone, until the inherent contractile resistance of this muscular mass governing the joint is entirely neutralized by the power exerted by the extender.

The two fixed points for extension by this method are gained through the neutralization of the muscular contractile resistance by the extension exerted and by a firm attachment to the limb over the insertion of the muscles (so that the extending force will always be directed toward their origin); and thus the only part of the muscular system of the entire limb which becomes relaxed is that lying between the two attachments, immediately over the joint (see Fig. 5).

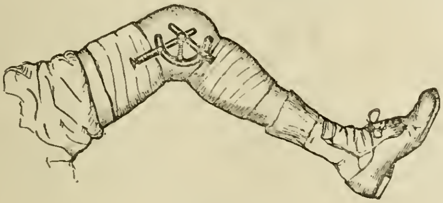

Fig. 5.

We have a simple splint in surgery which will meet all these various indications. I devised it some two years ago, and have since faithfully tried it in every form of disease that I could obtain and on every joint, and each case seems to develop new possibilities.

It consists of two slotted strips connected to a slotted sector by three clamps, and can be readily inserted into any form of attachment.

I have given it the name of the "Sector splint," and its construction is such that it enters as a curative element in every known form of joint disease. If properly attached—and no joint splint is properly attached if it be not fastened so as to directly oppose the power of the muscles controlling the joint—it is capable of the following combinations without removal from the limb:

1. *Extension at any angle with motion*, the degree of which may be exactly limited. This is the only splint known by which this can be produced.
2. *Extension* at any angle, with *fixation*.
3. Exposure of the entire surface about the joint, admitting elastic compression, hot and cold applications, blisters, dressings, and easy inspection.
4. Production of passive motion when required.
5. The production of elastic extension, with motion, by the addition of appropriate rubber cords. This alone opens up an entirely new and useful field which will be treated of in a subsequent article—combining, as it does, support, extension, and elastic education of muscles with deficient power to which so many of our deformities are due.
6. Gradual reduction of deformities and anchyloses.

Now as regards the attachment of the sector splint. The sector may be readily inserted into any form of brace attachment known. But when it is desired that the splint should remain upon the limb for any length of time, or, as in acute inflammation of joints, where it is used to reduce the contractile antagonism of the muscles, I prefer to use it in the form of a bracket, which is to be attached to the affected part by some immovable dressing, which will be sufficiently inflexible to prevent unequal pressure upon the soft parts.

The sector bracket consists of two terminal plates of thin copper, perforated upon the upper side, connected with each other by a sector bridge raised to any desired distance from the surface. This bridge consists of two overriding slotted steel strips, connected by three clamps which may be either thumbscrews or key-clamps. To this has been added a ratchet upon the upper bar for further increase of extension without alteration of angle (see Fig. 6).

With regard to the attachment of this bracket, I prefer my combination dressing of swans'-down adhesive plaster and flour paste, to the plaster-of-Paris so much in vogue, because: 1st, it is much lighter; 2d, it is more cleanly; 3d, it adjusts itself as perfectly to the surface, and has no subsequent expansion or contraction in bulk—one of the chief demerits of plaster-of-Paris; 4th, its adhesive properties.

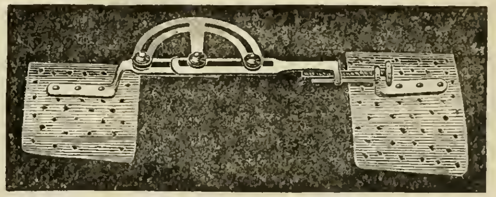

Fig. 6.

For example. Suppose the knee to be the affected joint upon which the sector splint is to be applied with this dressing. When dry, this dressing forms the segment of a hollow inflexible cone which has firmly grasped the muscular structures above and below the joint—the smaller end of the cone being nearer to the joint—and thus any extensible force which pushes these segments farther apart acts directly antagonistic to the inherent strength of the muscles—causing them to assume less bulk, without reducing their vitality in the least or interfering with their capillary circulation, and since one segment is over the bulk of the thigh muscles and the other segment is unalterably fixed over their insertion just below the knee-joint and for a little distance beyond the convexity of the calf-muscles (as some of the fibres of the thigh tendons are finally lost in the fasciæ of the leg), it will be seen, when extension is produced (by pushing up the upper strip of the sector and fastening the upper clamp, leaving the other two loose, thus allowing motion), *that the reflex contractility of the muscles of the joint, and the weight* are both transferred to the sector and its attachments, thus placing the joint in the very best possible condition for recovery by making it to all intents and purposes a dead joint (see Figs. 5 and 7).

This splint justly claims to be not only applicable to every joint, but also applicable to fractures and diseases in the continuity of bones.

It is at present in the infancy of its development, but enough has been demonstrated by its various uses to show us that we have in it an unprecedently successful splint in all diseases and conditions of joints.

CLINICAL OBSERVATIONS IN OPHTHALMIC PRACTICE.

NOTES READ TO THE ACADEMY OF MEDICINE AND SURGERY IN THE POLYTECHNIC SOCIETY OF KENTUCKY.

BY PROF. DUDLEY S. REYNOLDS, M.D.,
LOUISVILLE, KENTUCKY.

CASE I.—On the 27th of July, Burton Wilkes, a lad aged sixteen, was struck in the right eye by a No. 5 shot projected from a gumbo-shooter in the hands of a boy forty yards distant. The shot struck the nasal margin of the cornea and passed under the inferior retro-tarsal fold. I was passing the street at the time, and being observed by the boy's father, was halted and requested to examine the eye. Less than fifteen minutes after the receipt of the injury the anterior chamber was filled with blood. The cornea at the nasal margin was depressed and looked as though it had been perforated. Careful examination, however, showed that it had not. I ordered a solution of atropia and directed the boy to bathe his eye in cold water.

The next morning there was considerable tension of the globe, the ocular conjunctiva being suffused, lids œdematous, intolerance of light, circumorbital pain, the anterior chamber still being full of blood. The pulse was 120; the tongue dry; temperature, 102°. I ordered five grains each of calomel and chlorate of potash to be taken at once, and twenty grains of quinine to be taken immediately after the purgative effects of the powder.

July 29th the patient's general condition was much improved, the pain had disappeared, and the blood had commenced to undergo solution in the aqueous humor.

August 2d the clot had entirely disappeared, the aqueous chamber being perfectly clear. Careful examination with oblique light disclosed a circular depression in the surface of the crystalline lens, about half-way between its anterior pole and nasal margin. A circular opacity of the cornea, very near the scleral margin on the nasal side, marked the point of the former depression.

Radiating in every direction from the depression in the surface of the lens were to be observed opaque striæ, $S=\frac{20}{xxx}$. It was not known at this time that the shot had lodged in the inferior retro-tarsal fold, nor was its presence there suspected until August 21st, when I accidentally depressed the lower lid with my finger, and the shot rolled out. It had created no irritation—remaining from the 27th of July to the 21st of August, all the while in contact with the delicately organized mucous membrane, the shot being eroded and no sign of irritation of the membrane present.

CASE II.—A negro boy, fourteen years old, had been fighting, and was gouged in the eye by his antagonist. After the fight he was washing his face, and discovered that he was blind in the left eye. He suffered no pain, and the eye exhibited no evidences of contusion or other injury. Ophthalmoscopic examination disclosed a rent in the retina immediately surrounding the optic disk, extending more than three-fourths of the way around. None of the large vessels of the retina were ruptured, and that there had been no hemorrhage was evident. The traction had been so great upon the globe as to sever the continuity of the retina around the margin of the disk.

I saw him first on the 9th of August, and again on the 17th. No inflammatory reaction followed the injury. He has had no pain, the rent has widened, and the whole retina has assumed a milky haziness. It is scarcely necessary to mention that from the first he had no perception of light in this eye. I mention the case on account of its rarity, as well as the grave character of the injury, and the extraordinary immunity from pain and inflammatory symptoms.

CASE III.—A little girl, about eight years old, a bright child, playing with a fan, slipped and fell, the end of the fan striking her full in the eye. She complained of flashes of light, of many-colored spots floating before her, and was brought to my office for examination. I saw her twenty-four hours after the injury. The eye was watery, conjunctival vessels suffused, and the pupil widely dilated. I was at first unwilling to believe she had not been subjected to the influence of atropia or some other mydriatic. Ophthalmoscopic examination, however, revealed the startling fact that the retina was completely detached and floating loose in the vitreous chamber.

CASE IV.—A lady, about fifty years of age, of high social position, perfectly temperate, and pious in her habits, had for a long time suffered from an irritation in the throat which was greatly aggravated during the act of swallowing. The uvula was natural in appearance, except at its base, where an encysted tumor, causing an elevation of about two lines above the surface, appeared, perfectly ovoidal in form, and which had been growing slowly for more than two years. There was no local inflammation, but at every act of deglutition a tearing sensation upon the left side of the uvula was experienced.

I made an incision, and removed what appeared to be an encysted fibroid. Under the microscope it was readily seen that the encysted growth was composed, in the main, of steatomatous material, with an abundant supply of connective tissue. The removal of the growth was followed by considerable soreness and aggravation of the difficulty in swallowing for two or three days. On the 8th of August, four days after the operation, the local discomfort had entirely disappeared, and the act of deglutition was unattended by any disagreeable sensation whatever.

Case V.—Miss W——, aged about twenty-four years, suffered more or less discomfort in attempting to read, and especially at night, during the last seven or eight years, and had sought the aid of a dozen or more oculists, who made hasty examinations and prescribed glasses which were thought to be more or less comfortable for a time, but the sense of dryness, heat, and pain in the eyes, with the intolerance of light and the difficulty to trace lines, always returned on attempting to read at night.

She had more than two dozen pair of spectacles, not one of which gave immunity to the suffering. Recognizing this as one of the almost innumerable cases requiring very careful examination, I ordered a four-grain solution of atropia to be dropped into the eyes every morning and evening for five consecutive days. At the end of that time an attempt to test the state of refraction revealed the fact that the accommodative function was still exercised. The patient was directed to continue the drops for two days longer, and, on returning, the accommodation was still not fully suspended. Two more days—making nine in all—were employed in the persistent use of the drops both morning and evening. On the tenth day the accommodation was found fully suspended, and the following defects of refraction observed. In the right eye, hypermetropia = to $\frac{1}{36}$ was observed. In the left, hypermetropia = to $\frac{1}{72}$ in meridian 130°, and in the meridian at right angles to this hypermetropia = to $\frac{1}{36}$, thus disclosing astigmatism in the left eye = to $\frac{1}{72}$. She had been using $+\frac{1}{36}$ for both eyes, with little improvement to her vision, and no immunity from the suffering. On correcting fully all the defective refraction observed, she has been able to make continued use of her eyes for writing all day, and almost constant reading for two or three hours at night, with perfect freedom from pain or any sort of discomfort. I report this case to show that asthenopia of a very troublesome character demanded the correction of an astigmatism existing in one eye only, and equalling but $\frac{1}{72}$, whereas it is taught by Donders and others that astigmatism of less than $\frac{1}{40}$ is of no particular significance, and never requires correction. It has been my constant habit, for more than ten years, to make full and complete correction at once in all cases of hypermetropia, and to correct the least grade of astigmatism observed in reading Snellen's test-letters. These I regard as affording a more practical and delicate test of defective refraction than any of the numerous devices of radiary lines, not excepting Pray's test of letters, formed of sections of lines running in different meridians. It is a more practical way of testing astigmatism than with the optometer of Thompson, Graefe, or Young.

The relief obtained by Miss W——, whose case I report to illustrate a class by no means rare, is conclusive argument against the doctrines of Donders and others who regard low grades of astigmatism as unworthy of notice.

LARYNGOTOMY FOR MEMBRANOUS CROUP.

Operation after Cessation of Respiration—Death from Accidental Asphyxia Five Days after Operation.

By ALFRED NORTH, M.D.,
WATERBURY, CONN.

Louise Miller, aged eleven years, born of healthy parents, was brought to my office on the afternoon of February 18, 1880. The only subjective symptom of which she complained was intense dyspnœa. Pulse, 110; temperature, 103°. Auscultation showed moist bronchial râles on both sides; respiratory murmur feeble, especially on left side; and other evidences pointing to congestion of left lung. Ordered a mercurial cathartic; quinine, ten grains, an expectorant mixture, and steam inhalations.

February 19th.—Was unable to see the patient again until 7 p.m. to-day, when I found her breathing very laboriously, face dusky, and apparently very little air entering either lung. Respiratory murmur very feeble; percussion sound moderately dull over both lungs, especially so on left side. She was lying, and it seems had lain since my seeing her yesterday, in front of a window where a draft of air was distinctly to be felt. Caused her to be moved to a large, well heated and ventilated room, and ordered the steaming to be more vigorously kept up than ever. 10 p.m. called again, and found her breathing still more labored, so much so that I feared without surgical interference she would die from asphyxia before morning. I therefore urged the necessity of laryngotomy, but the consent of the parents could not be obtained.

February 20th.—I went away so sure in my convictions that death would ensue during the night, that I did not call to-day until about 10 a.m., when I was summoned by the message that she was dying. I found this was indeed the case, and urged upon the parents the necessity of an operation as the last resort. Consent being at last obtained, the patient was laid upon the table and preparations speedily made. While deliberating upon the best point at which to open, respirations suddenly ceased entirely. Artificial respiration was immediately commenced and kept up by Dr. Barbour, who was assisting me, and, without more delay, the knife was entered and the larynx opened through the crico-thyroid membrane. This procedure was followed by the forcible expulsion through the opening of a large amount of muco-purulent matter, which was so tough and tenacious that much of it, after being forced nearly through the opening, would be drawn back during inspiration, unless retained by the sponge. Some minutes were thus occupied before time could be found to introduce the tube. Again respiration ceased, and this time the pulse was wholly lost, both at the wrist and cardiac apex. Both, however, were soon restored on resuming artificial respiration. There was so much trouble in the expulsion of the tenacious mucus that a suction-pump was applied to the tracheotomy-tube, and with each withdrawal of the piston the face brightened and the former dusky hue rapidly disappeared.

No anæsthetic was employed. As patient was insensible through asphyxia, there was little or no hemorrhage, a few drops of blood only being lost. The double canula was used and secured by a tape in the customary manner. Respiratory murmur was now heard over both sides of chest. 5 p.m.—Six hours after the operation, the little patient is laughing and feeling very happy at her deliverance from suffocation. Respiration easy, but more rapid than normal. Seldom has it been my lot to see so great a change produced in so short a time by any operative procedure.

February 21st, 8 A.M., twenty-four hours after operation.—Patient passed a restless night. The bronchial secretion appears to have almost entirely ceased, and a dry, nearly continuous cough annoys patient exceedingly. Temperature, 103°; pulse, 120; respiration, 40. Slight dulness on left side, and diminished vesicular murmur. Soft mucous râle on right side. Refuses all nourishment. Discontinued the use of Weir's steam atomizer, which up to this time had been constantly employed, and in its place used ordinary steam from an improvised apparatus. Covered the entire chest with a lye and bran poultice, and ordered milk and brandy. 10 P.M.—Patient a little easier; bronchial passages less dry, but very little secretion thrown out. After using the simple steam for two hours a return was made to the atomizer at the patient's request, as it gave so much more relief.

February 22d.—Patient much more comfortable this morning, sleeps well, and breathes quite naturally through the tube. Temperature, 100¾°; pulse, 110; respiration, 21. Desires and takes all the nourishment necessary. During the night forced through the tube several pieces of hard, partially desiccated mucus, about half the size and thickness of an ordinary peanut.

Bowels moved three times during the night. Atomizer steadily used; patient soon becomes very restless when its use is interrupted. Cannot get breath when the tube is closed by the finger.

Monday, February 23d, 7 A.M.—Patient has passed quite a comfortable night, sleeping frequently for half an hour at a time. Temperature, 102°; pulse, 118; respiration, 30. 11 A.M.—Was hastily summoned to find the patient tossing from side to side and laboring very hard to breathe, very little air entering the lung. In considering what to do, a case occurred to me that came under my observation in 1864. The case was one of diphtheria in which, to prevent impending asphyxia, tracheotomy had been done. After a time, as in the present case, the accumulation in the trachea and bronchi seeming likely to cause a fatal result, in order to provoke coughing the bronchial passages were washed out with a solution of salt and water. The procedure was very successful, a large piece of membrane and much tenacious mucus being ejected, from which moment the child began to mend. I therefore at once resorted to this measure, using a solution about the strength of sea-water. With a long, curved rubber syringe I threw in about half an ounce. Violent coughing immediately ensued, during which membrane and large pieces of tough, inspissated mucus, resembling glue in texture and appearance, were thrown off. The operation was repeated in a few minutes, and was followed by a like result, after which the patient fell back and slept quietly for half an hour. For the first time to-day some of the nourishment given found its way into the trachea and was thrown out through the canula. At first I feared this might be caused by the canula sloughing through into the œsophagus, but subsequently found was to be due to the paralysis of the laryngeal muscles. I now directed that nourishment should be given per rectum, beef-juice and pancreatic emulsion being employed for the purpose; brandy and quinine administered in the same way.

The bronchi required to be washed out repeatedly—each washing followed by the expulsion of membrane and mucus as before, and by great relief from dyspnœa for five to six hours. When the passages became obstructed and the breathing difficult, the child would herself call for the salt and water.

February 25th.—At my usual morning call I found the patient sleeping so quietly that I did not awaken her. She seemed to breathe so easily and appeared so well that nourishment was again attempted by the mouth. A portion of this passed into the larynx and bronchi. Severe dyspnœa immediately ensued. I was hastily summoned, but found myself powerless to relieve the trouble, and thus, in the space of an hour after her quiet sleep and hopeful appearance, on the fifth day after the operation, she died of accidental suffocation.

Post-mortem, made the following day. The epiglottis standing erect, the larynx lined with a thin, diphtheroid membrane; the trachea below congested, but having no membrane, presented an appearance suggesting the probability that a membrane had recently been thrown off.

Permission to examine the lungs could not be obtained. The left one I believe to have been affected with catarrhal pneumonia. The practical lessons to be learned from this case I consider to be:

1st. That after operations upon the larynx or trachea, where the nourishment given regurgitates into the air-passages, rectal alimentation should entirely supplant feeding by the mouth.

2d. That, as is indicated in this case and proved by experience in innumerable others, the operation is in itself not a dangerous one, and must of itself be exceedingly rarely, if ever, a primary cause of death; therefore, we should undertake it far oftener than is at present done in this country, especially in children dying from suffocation in simple croup. That even the nearly total absence of vesicular murmur need not render the case hopeless, for in this instance the murmur returned as soon as the opening of the trachea admitted sufficient air to expand the lung.

I have a case in mind where I now regret exceedingly not having operated, in which I was deterred at the time mainly by the almost complete absence of vesicular murmur over the entire chest.

Dr. Leale recently reported a successful case to the Academy of Medicine in New York, where the false membrane had filled the larynx, penetrated to the small bronchi, as well as extending down the œsophagus into the stomach.

The benign and simple nature of the operation may give us confidence that, even in those cases where we do not save life, at least we have done no harm. Furthermore, even when a fatal result ensues, something has been gained, for, as Dr. Gross says, "it is the easiest way for the patient to die." Although the laryngeal tube was employed in this case, I would avoid its use wherever practicable, and thus do away with the irritation which its presence is liable to cause.

A plan for doing without it was, I remember, prominently brought forward by Dr. Henry Martin, of Boston, in a paper upon the subject read before the American Medical Convention in 1872. He had employed this plan for sixteen years with very favorable results, being first obliged to do it in a desperate emergency, when he had at his command only an ordinary thumb-lancet and a needle and thread.

His plan, in brief, was, after making the opening into the trachea, merely to stitch together the outer and the inner margin of the wound with a single thread on each side, draw the wound sufficiently open by these threads, and keep it so by fastening their ends to a rubber plaster passed about the neck.

As to the time of operation, I would not recommend so early a resort to it as is advised by most French surgeons; not necessarily waiting, either, till the case had become almost or quite hopeless; but, after a fair and thorough attempt to relieve by other means steadily increasing dyspnœa, I would proceed to operate, feeling sure that if this were generally done, many cases might be saved which we now allow to die.

Reports of Hospitals.

BELLEVUE HOSPITAL.

Notes of Practice and Peculiarities of Treatment.

PNEUMONIC FEVER—ACUTE LOBAR PNEUMONIA—ANTIPYRETIC TREATMENT BY THE USE OF COLD.

The case of pneumonia seen was interesting, espepecially with reference to the method of treatment. A male patient, aged twenty-one years, a cooper, and a native of the United States, was admitted to the hospital September 29th, without important family history. He had had intermittent fever more or less during the last three months, and also had been dissipated in his habits. During the week immediately preceding the present attack there *was no recurrence* of the chill, and he felt well. On the 26th he had a short, severe chill, and naturally enough his first thought was that it was the beginning of another paroxysm of intermittent fever. The chill was followed by vomiting, fever, and a sharp lancinating pain in the left side, in a circumscribed space near the nipple. To the fever and pain were added cough, and he soon began to expectorate. On admission he still complained of pain in the side, shortness of breath, severe headache, and a general feeling of illness. His countenance was anxious, his face flushed, his respiration accelerated and panting, his pulse 120, his temperature 104½° F., and he was expectorating distinctly rusty material. On physical examination there were found over the lower lobe of the left lung increased vocal fremitus, dulness on percussion, broncophony and pectoriloquy. The last physical sign is not common with simple solidified lung. On the next day after admission, September 30th, his temperature in the morning was 104° F., and at 12.30, 105° F., and then he was placed in the cold, wet pack—that is, the body, nude, was wrapped in a wet sheet, which was sprinkled with cold water at short intervals. He remained in the pack two hours and fifteen minutes. It was agreeable to the patient, and he subsequently called for the pack at times when its use would not have been advisable.

At 2.30 P.M. his temperature in the axilla had fallen to 103° F., and at 2.45 P.M. to 102° F.—a good illustration of the fact that the temperature sometimes falls considerably after the patient is removed from either the pack or bath. The rule adopted in this case was to resort to the cold pack whenever the temperature rose above 103° F. At 3.30 P.M. his temperature was 103½° F., and he was again put in the pack, where he remained an hour and a half, and his temperature was reduced to 101½° F. One hour subsequently, at 6 P.M., his temperature was again 104° F., and at 6.30 P.M. the cold pack was renewed, where he remained one hour and a quarter, when his temperature was 102° F.

October 1st.—Morning temperature, 100¾° F.; noon temperature, 104° F. At 12.15 P.M., 104¼° F., and he was again put into the cold pack. At 12.45 P.M. his temperature was 103¼° F., and at 1.15 P.M. it was 102° F. At 3 P.M. his temperature was 102¼° F., and at 6 P.M., without further antipyretic treatment, his temperature was 101° F. It was believed to be a fair suspicion that the malarial element in the case was exerting some influence on the temperature curve.

October 2d.—Morning temperature, 102¼° F.; noon temperature, 103° F. Temperature at 3 P.M., 102° F., and at 6 P.M., 101¼° F.

October 3d.—Delirious, and succeeded in getting out of bed once. Morning temperature, eight o'clock, 103¼° F., and he was put in a pack, where he remained an hour and a quarter, when the temperature was 103°. At 9.30 his temperature had fallen to 100¼° F.; at 12 M. it had again risen to 102¼° F. At 3 P.M. his temperature was 102° F., and at 6 P.M. 101¼° F.

October 4th.—Delirious through the night. At 8 A.M. his temperature was 99¼° F.; at 12 M. 98½° F., and *râles redux* were heard distinctly. At 3 P.M. his temperature was 97½° F., and at 6 P.M. the same.

October 5th.—The treatment up to this date consisted of milk and eggs for food, half an ounce of whiskey every two hours (having been accustomed to the use of alcohol), carbonate of ammonia, *five* grains every two hours, and morphine sufficient to relieve the pain and secure rest. His temperature at 8 A.M. was 97° F. His expectoration on this date was mostly a yellowish mucus.

October 6th.—Morning temperature, 97½° F., and the evening temperature was the same. Urine normal. Evidence of resolution of the solidified portion of the lung well marked, although there was marked dulness on percussion, due to plastic exudation remaining. The tympanitic resonance from the stomach was propagated upward, and prevented the outlining of the intra-lobar fissure. The patient was regarded as convalescent.

NON PROGRESSIVE CIRRHOSIS OF THE LIVER—PLEURISY WITH EFFUSION—THORACENTESIS—RECOVERY—A SECOND ATTACK OF PLEURISY.

The following case presented two interesting features, one with reference to the liver and the other referable to pleurisy. A male patient, aged forty-two years, a barber by occupation, a native of Canada, was admitted to the hospital October 4th. His family history was unimportant. He had been accustomed to the use of alcoholic drinks. Five years ago he had acute articular rheumatism, and he had had syphilis. Four years ago—and here is one of the interesting features—he had ascites, with œdema of the feet, and a careful examination made in the hospital at that time reached the diagnosis of cirrhosis of the liver. Since that date he had not drank any stimulants, except occasionally a glass of beer, and had not suffered from *any* of the symptoms of the disease. He had been able to stop the use of alcoholics, and the cirrhosis had become *non-progressive*, and he was apparently free from any disease except the pleurisy, for which he came into the hospital.

Two years ago he came into the hospital with pleurisy in the left side, and he was tapped and ℥ lx. of fluid withdrawn. *He then fully recovered, and was* *able to work as well as ever* up to his present illness. Ten days before admission to the hospital he had a chill, and on the following day cough and sharp pain in his side, and he was so sick that he took to his bed. On admission, physical examination revealed evidence of pleurisy, with effusion on the left side. *There was no evidence of phthisis.* Diagnosis of pleurisy with effusion was made positive by the introduction of a hypodermic needle and withdrawing serous fluid. The quantity of fluid present was not large, and the chief item in the treatment was to put the patient's general nutrition in the best condition possible. A blister was not objected to, although it was not recommended.

Progress of Medical Science.

A Case of Chondromyxoma of the Uterine Cervix.—Dr. G. Reier demonstrated to the St. Petersburg Society of Russian Physicians specimens of an exceedingly rare form of malignant growth, the proper name of which should be myxoma enchondromatodes papilare s. arborescens. A case similar to this was also described by Thiede in *Zeitschr. f. Geburtsh. und Gynæc.*, 1877, Bd. i., H. 12. More recent case of Spiegelberg (*Arch. f. Gynæc.*, Bd. xiv., H. 2, p. 178) bears a strong resemblance to the two above. Patient was single, twenty-one years old. The tumor began to grow a brief period previous to May, 1874, as the first symptoms referable to the uterine disease appeared at the end of 1873. The growth gave rise to severe pelvic pains, profuse leucorrhœa, menorrhagia, and metrorrhagia, and to failure of general health. She was admitted to the hospital March 4, 1875, and a part of the tumor was removed then, the remaining portion six days later. Very soon the tumor made its appearance again, and a second operation was undertaken September 29th. Patient died the following day in collapse, with the symptoms of commencing peritonitis. Tumor, with the part of cervix removed with it, weighed 100 grammes, was of soft consistence, light color; the surface of its main portion was covered with small, round, secondary growths, having the general appearance of a bunch of grapes. Tumor was composed of myxomatous tissue, with cartilaginous nuclei distributed through its substance.—*Transactions of the St. Petersburg Society of Russian Physicians*, 1879–1880.

On Albuminuria and Peptonuria.—Dr. A. Dochman read a paper on the above subject before the Kazan Medical Society, the essence of which was that the presence of albumen in the urine is neither due to changes in the albuminoid substances of the blood, nor is always determined by the diseases of kidneys, being frequently absent in the case of the latter. Conditions determining its presence are as follows: 1. Increased pressure in the renal arterial system, causing static and active hyperæmia. 2. Various diseases—inflammations and degenerations of the parenchyma of the kidney, and of the entire urine-secreting apparatus. 3. Various febrile diseases—typhus, small-pox, scarlet fever, etc. 4. Various diseases of the brain and spinal cord (even mental excesses): inflammations, concussion, epilepsy. Here belongs also albuminuria, produced by diabetic puncture and the albuminuria of hydrophobia. 5. Poisoning by various substances: cantharides, carbolic acid, arsenic, morphia, alcohol, and phosphorus. 6. Irritation of the skin by chemical, thermic, and electric agents. Here belongs, also, the albuminuria of miliary fever. 7. Injection in the vessels, and even introduction of large quantities in the stomach of the white of the egg. Injection of defibrinated blood or water. 8. In some cases it appears in perfectly healthy persons; for instance, after forcible muscular exercises; also, in anæmic patients. 9. Ischæmia of kidneys, compression of renal artery, suffocation; here also is the albuminuria in cases of intestinal catarrh. Recent investigations prove, also, its occurrence if the arterial pressure is lowered in the vessels of Malpighian tufts (with the increase of pressure in the urinary tubes). 10. Diminished quantity of chloride of sodium in the system leads to the albuminuria, the same disappearing after quantitative restitution of this substance.

All these numerous agencies determine albuminuria, not directly, but by inducing, first, changes in the filtering apparatus, the walls of the vessels of Malpighian tufts (where the filtration of albumen exclusively takes place), changes of such a nature that permit the escape of albumen through them.

Peptonuria, which is the presence of peptones in the urine, with or without simultaneous presence of albumen, attracted considerable attention within the last few years. According to Maixner (*Cntbl. f. m. Wiss.*, 1879, No. 33), peptones are found in the urine in cases of profound disorders of general nutrition, such as acute phosphorus-poisoning and local morbid processes, of which number purulent processes and croupous inflammation of the lungs are invariably associated with peptonuria.

Dr. Dochman, as the result of very extensive analyses, arrives at the following conclusions: 1. Peptonuria is not a disease, *per se*, and is different from albuminuria. 2. Peptones of the urine do not come directly from the blood, but are the artificial products, developed outside of the circulation, in a minor degree, in the urinary tubes, but to the greatest extent after the urine is voided. 3. Peptones are the results of urinary digestion of albumen, a process analagous to the gastric digestion, and the existence of which is proved by the following facts: *a.* Brukke proved the presence of pepsine in urine a great while ago, and Potiechin (personal communication to the writer) recently found, also, peculiar substances of acid reaction. *b.* Transformation of albumen in peptones is retarded, if the urine, after being voided, is kept at the temperature of 0° C., or its acid reaction is neutralized by alkali. *c.* Urine, if it is alkaline when voided, contains only the traces of peptones, or none at all. In acid urine, containing a good deal of albumen, the amount of peptones increases with time, and at the expense of albumen.—*Transactions of the Kazan Medical Society*, 1880, April 8th.

Pathology of Oxalic Deposits and Stones in Human Urine.—As the result of a thorough study of this subject Prof. Schtscherbakoff arrives at the following conclusions: Freshly voided urine does not contain free oxalate of lime. Decomposition of an unknown compound group takes place, one of the products of which is oxalic acid. The latter displaces calcium from the lime combinations, forming with it an imperfectly soluble oxalate of lime. The same urine does not contain either oxaluric acid, so that it cannot be considered as the source of oxalic acid, and is also due to the decomposition of an unknown compound. As the substance from which oxalic acid is derived is readily decomposed by acids and substances of acid reaction, its formation is to e associated with acid fermentation of urine. Although acidity of urine is a necessary condition for he formation of both deposits and stones, there exsts a very important difference, as the former are lways colorless, while the latter are always of a dark olor. This fact indicates that the formation of stones can hardly be as simple a process as the formation of deposits. The nuclei of oxalic stones are always either urates alone or the mixture of urates and free uric acid, surrounding which is the layer of oxalate of lime. This layer always contains urates, its color is in proportion to the amount of the oxalate, and there is also iron, amount of which is in direct proportion to the quantity of oxalate and the depth of color. Analyses show also the presence in it of hematine (coloring matter of calculus). Hematine and iron strongly point to the fact that the formation of calculi is intimately connected with the effusion of blood. To enable the study of this point he produced the calculi artificially, by taking frog's blood in a vessel and pouring gently over it some human urine (with the addition of a few drops of carbolic acid), after the former gave a solid clot. As long as red corpuscles were not destroyed, no crystals of oxalate of lime were to be found. They appear with and in proportion to the disappearance of red blood elements. Usually, on the third or fourth day, portions of blood-clots can be easily found, containing not a single corpuscle, fibrine threads being profusely infiltrated with the oxalic crystals. The latter cannot be found in the urine above the clot, or in the same urine kept for comparison, even after three weeks. It would appear then that the formation of oxalate of lime depends upon the disintegration of red blood-corpuscles. But after a while the latter cease to break down, infiltration of the clot with the crystals stops, and yet the deposit of salts above it keeps on, showing that it is derived from the ingredients of urine and not from the substance of blood-corpuscles. This apparent contradiction he intends to clear up in the course of his present studies. He reports also the presence in the oxalic layer of cholesterin, and of crystals very closely resembling those of impure leucine. His studies would suggest then that the oxalic calculi are an accidental occurrence in the course of the formation of uric stones, depending upon the escape of blood, this accident being indicated by an oxalic layer, for the time-being the energy of uric growth is retarded, but not arrested entirely. When the disturbance produced by hemorrhage subsides uric process is resumed again and it continues until a new escape of blood occurs again. This theory gives account for all peculiarities, alternate laminated appearances of these stones included.—*Transactions of the Kazan Medical Society*, 1880, Nos. 8–12.

[We would like to have Prof. S.'s explanation of that rare form of oxalic stones which are perfectly white (renal stones)].

A Case of Rupture of Rectum with Anal Orifice and External Sphincter Intact—Recovery.—The patient, fifty-five years old, glazier by trade, suffered from rectal prolapse for the last twenty years. He carried a very heavy case, and crossing hurriedly a street he stumbled, falling on a prominent part of the pavement. He struck the abdomen with such a force that the bowel protruded, followed by a very severe pain in the rectum and a hemorrhage from the anus. Being taken to the police station a trained nurse replaced the prolapse. Hemorrhage ceased, pain lasted for five days, hypogastrium became tender, constipation occurred and fever ensued. On the fifth day he was admitted to the hospital. On examination the rectum was found ruptured to the extent of six inches, running across the anterior right wall of intestine obliquely from above downward and from before backward. The edges of the wound were gaping widely and very much infiltrated. As the result of injury phlegmonous inflammation of periproctal tissue occurred, also extending in ischio-rectal fossa, from which he recovered. Laceration of rectum healed also, and he left the hospital cured about seven weeks from the date of injury. As the result of inflammatory process around the rectum the prolapse was cured also. The mechanism of rupture is easily understood, if we compare the abdominal cavity to the cartridge chamber of a gun, the pelvis to the bore, and the rectum to the charge, with the difference that the rectum is attached by muscles and connective tissue to the adjoining parts, and its forward movement is arrested by adhesions, but as the force is great, the rectal tissue gives away.—*Meditz. Vestnik*, 1880, Nos. 410, 411.

Subcutaneous Emphysema occurring during Labor.—Dr. Lwoff finds only three cases of this condition reported in *Irish Hospital Gazette* for 1873, pp. 38, 165, etc. His patient, a primipara, was admitted to the Kazan University obstetric clinic on Feb. 8, 1880. She was a healthy, robust young woman, with normally developed parturient canal, and was delivered of a healthy child after normal labor. At the close of the first stage of labor Dr. L. observed that the patient's face grew puffy, her neck became very thick, so that all natural depressions on it disappeared, and the face grew cyanotic. Examination of the parts revealed very distinct crepitation, which was not superficial, but extended quite deep into the tissues. Emphysema extended to the insertion of platysma myoides and mastoid processes of temporal bones, and downward it reached to the third ribs. Posteriorly it did not extend beyond the anterior borders of trapezii. Patient complained of pain in the throat, slight cough, and difficult deglutition. On auscultation after labor breathing at the apices was found, harsh, but vesicular in character. Percussion of the chest normal. Breathing, at first 32 per minute, soon fell to 20. No dyspnœa. On the third day emphysema began to disappear and left no traces on the seventh. Patient left the hospital entirely well the following day.—*Meditz. Vestnik*, 1880, No. 34.

Olive-Oil in Large Doses for the Softening and Easy Expulsion of Biliary Calculi.—Dr. Roderick Kennedy, Kingston, Canada, has found olive-oil given in large doses to be the desideratum for softening and promoting an easy expulsion of biliary calculi. In the *London Lancet*, September, 1880, he says that in every instance in which calculi were proved, or presumed, to have been the cause of periodic suffering, these bodies were promptly and painlessly expelled in larger or smaller quantities by the use of *large* doses of olive-oil. Three cases are cited with the symptoms of the passing of gall-stones. All the usual remedies were employed, but no appreciable effect on the pain was obtained until the olive-oil was used; six ounces of the oil were administered at bedtime, followed in the morning by a full dose of castor-oil. When there was no action of the bowels an enema was given, which was usually followed by several copious motions containing softened gall-stones. The administration of the oil at intervals of a few weeks or months prevents the re-formation of the concretion for the time, but still the oil alone does not alter the causes or diathesis upon which the formation of these bodies depends.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, December 4, 1880.

THE ENFORCEMENT OF THE MEDICAL LAW.

Now that we have a law regulating the practice of physic, a very natural question arises as to the means at our command for enforcing it. It is hardly to be expected that the individual practitioner will undertake to be the prosecuting party unless, perhaps, in isolated cases, and under peculiarly aggravating circumstances. At best such cases will be few compared with the aggregate number of unqualified practitioners who will need attention. Occasionally some outsider may enter a complaint against an unregistered man merely for the sake of half the penalty which he may receive. But the possibility of such occurrences will be slight, and the results following therefrom will be comparatively insignificant. In this as in all other similar matters in which the true interests of the profession are concerned, the profession must act in a corporate capacity, through one or other of its societies. It requires no second thought to determine the proper organizations. These are the county societies throughout the state. Such organizations are thoroughly representative in character, are, as a rule, composed of all the reputable practitioners of a given district, and are interested in maintaining the rights and privileges of their individual members. The Medical Society of the County of New York has possibly taken the initiative in this matter, at least so far as regards preparing its treasury by extra assessment for increased outlay in prosecuting irregular practitioners.

There is no doubt that this is the best way to solve many of the difficulties which must necessarily attend the practical working of the law. The extra assessment of $2 per member upon the medical society in this county will not be felt, and will no doubt be cheerfully paid. We are not informed of the pecuniary ability of other county societies to meet similar extra expenditures, but if more funds are needed the example of our own society should be followed.

If the medical profession as a body show no interest in seeing the law enforced, it will become a dead letter upon the statute book. Perhaps never before was such a good opportunity offered to pit legitimate medicine against quackery, and create a proper public sympathy for the former. The central idea of the law—that of registration of qualified practitioners—is so simple that the public are already prejudiced in its favor.

The Medical Society of the County of New York is the fitting one to set an example to other similar organizations throughout the state and prove the practicability of the law. If there are weak points in the law they can be tested in no better way than in the courts. When flaws are discovered they can be mended by future legislation. Until it is demonstrated to the contrary by actual tests before the proper tribunals the law must be considered perfect and the county societies through their proper committees should act accordingly. The details of action can be left with the different committees. Perhaps no better general suggestion could be made than that a committee should examine the register at least once every six months, and in their report to the society embody such suggestions and recommendations as may appear necessary to enforce the full letter and spirit of the law. But we presume that the other county societies are quite willing that the New York society shall take the initiative, and are prepared to await developments.

PASTEUR'S DISCOVERY OF THE "VACCINE" OF FOWL-CHOLERA.

M. Pasteur has at last made known the method by which he claims that the virus of fowl-cholera can be modified so as to produce a morbid disease which has the same protective power against the original disease that vaccinia has against small-pox. M. Pasteur's communication on the subject is of extreme interest, on account of the bearing which the alleged discovery has to all infectious diseases. Fowl-cholera itself is not a disease of much consequence; it is not a cholera at all, but is a highly virulent blood infection, characterized chiefly by fever, swelling of the cervical lymphatics, pericarditis, and duodenal congestion or inflammation. Its termination is frequently fatal, but not necessarily so, and the poison seems to differ in the degree of its virulence at different times. The special poison of the disease, according to Toussaint and Pasteur, is an oval-shaped micro-organism about $\frac{1}{40000}$ of an inch in diameter. This organism can be easily cultivated in certain media, such as decoction of muscle; and it was by cultivating it in these media that Pasteur obtained the results he now announces.

In describing his investigations, the facts of the variable intensity in the symptoms and course of the different infectious diseases is referred to. It being admitted that such a variability does exist, the problem proposed by the experimenter was to take the infective organism in cases of virulent fowl-cholera, and try whether by artificial cultivations the intensity of their effect could not be diminished. It was found that if these micro-organisms were subjected to numerous cultivations immediately succeeding each other, the virulence was not at all diminished; but if the intervals between the cultivations were prolonged, a gradual diminution in intensity did take place. Thus, for example, the germs from a very malignant case may be placed in a muscle-decoction, and there allowed to multiply. Multiplication having ceased, the decoction is allowed to stand for two months; some of it is then taken and placed in fresh culture-fluid, where growth and multiplication again occurs. Now while the inoculation of the first decoction will kill ten chickens out of ten, and that in a sudden manner, the virus of the second decoction does not kill all, or at least it will have lost its *foudroyant* character. If the time between the successive cultivations is extended to six, eight, or ten months, the virulence of the poison continues to become weaker, until it finally causes simply a mild disease that does not injure the fowl, but protects it from the effects of any further inoculations even with the freshest and most virulent organisms.

This is M. Pasteur's method of obtaining the protective virus of fowl-cholera.

The next question which he proposes is: What is the agent that causes this progressive diminution in the intensity of the special poison? He found that cultures which were kept preserved from the atmosphere in hermetically closed tubes did not lose their virulence in the least, although preserved for ten months in this manner. Cultures from the same source, that were exposed to the air, gradually lost their strength, as has been described. M. Pasteur finds in this fact a clear demonstration that it is the oxygen of the air which weakens or extinguishes the virulence of the poison; and he believes further that this is not merely an isolated fact, but possibly the grand principle that to this influence is due the modification and limitation of great epidemics.

This, as well as the other of M. Pasteur's communications on the subject of fowl-cholera, read very much like a romance. It must be said, however, that he is not alone in announcing discoveries of the kind just described. M. Toussaint states that he has been able to modify the poison of anthrax, so hat after its inoculation in healthy animals a morbid action is produced which removes the susceptibility to the original poison. Only in M. Toussaint's case the alleged infective germs were removed from heir fluid medium, instead of being cultivated in it. He took the blood of animals affected with anthrax and destroyed the organisms in it by filtration and carbolic acid. He then injected the filtered fluid into healthy animals, and found them protected by it against the anthrax.

Similar experiments with the virus of splenic fever have been made by Dr. Burdon-Sanderson and Dr. Greenfield. The latter showed that if a guinea-pig be inoculated with the blood of a heifer suffering from splenic fever, the former animal takes the disease. Then, if the blood of the guinea-pig be inoculated in a healthy heifer, it will protect that animal against splenic fever. Still other experiments by Buchner and by Koch, showing the apparent possibility of changing by cultivation the supposed specific properties of micro-organisms, have been made.

All these investigations have led their authors to conclusions which, if correct, are of a vast importance to pathology as well as to practical medicine.

While hoping that these experimenters are not deceived, we cannot but remember that the history of specific germs is full of the wrecks of brilliant hypotheses. From Hallia, with his rice-fungus, to Oertel, with the diphtheria spores, the story has been one of laborious experiment, alluring theory, then refutation, and final collapse. There is a remarkable medico-geographical fact also in this connection. It is that all the specific micro-organisms, except a few in Ohio, live on the other side of the Atlantic and cluster around the laboratories of a few pathologists. Therefore it is not surprising that some incredulity be shown toward specific germs, in whose geographical distribution there is shown such a conspicuous bias.

THE BENIGNITY OF SYPHILIS.

It is seldom that a committee on prize essays gives such good reasons for its action as did such a committee of the County Society of New York, in awarding its annual prize to Dr. Chas. L. Dana; and it is also rarely the case that the prize essay is upon such an interesting and novel topic. We are so much accustomed to associate syphilis with everything that is bad, that any claim for its benignity is somewhat startling. Still Dr. Dana attempts to prove this by a "conscientious and laborious study" of three hundred and seventy-eight cases occurring in seamen. Whether syphilis behaves differently with seamen than others, and whether their hygienic surroundings are capable of modifying the usual manifestations of the disease are questions of more than ordinary importance, especially in connection with several points brought out in the essay. At a future time we shall publish the essay in full.

THE FILTHY STREETS AND DISEASE.

The new Committee on Hygiene of the Medical Society of the County of New York consists of Drs. Janeway, Roosa, Billington, A. B. Judson, secretary, and John C. Peters, chairman. The subject which will principally be investigated by the committee is the condition of the streets and gutters of the city and the diseases arising therefrom.

It is claimed by some of the committee that a great deal of sickness and some deaths occur from the filthy condition of the streets and gutters alone, and many diarrhœal diseases, notably, cholera infantum in the summer, and diphtheria in the cooler months. An ordinary sore throat caused by taking cold in pure cold air will generally be simple catarrhal or inflammatory in its nature; but a sore throat contracted in impure air will probably be septic, malignant, or diphtheritic in character; and this foul air may be supplied by dirty streets and gutters alone. A great deal of street and gutter dirt is washed down into the receiving-basins and sewers by every rain-storm, and adds to the foul contents of the sewers, and increases the quantity and malignancy of sewer-gas. Much diphtheria is caused by sewer-gas, and a great deal of it is owing to the neglect of the street-cleaning department. We would suggest that every physician aid the Committee on Hygiene, by noting nuisances in his own neighborhood which injure his property and the health of his family, and report to the committee. Common humanity also requires that physicians should do this for their patients.

Reviews and Notices of Books.

Die Pneumatische Behandlung der Respirations- und Circulations-Krankheiten im Anschluss an die Pneumatometrie und Spirometrie. Von Dr. L. Waldenburg, Professor an der Universität Berlin, etc. Zweite vermehrte Auflage, erweitert um einen Beitrag über das Höhenklima. Mit Holzschnitten. Berlin, 1880: Aug. Hirschwald. 8vo, pp. 618.

The Pneumatic Treatment of Diseases of Respiration and Circulation, based on Pneumatometry and Spirometry. By Dr. L. Waldenburg. Second edition, containing an appendix on the climatology of high altitudes. Berlin, 1880.

Prof. Waldenburg is well known as the able editor of the *Berliner klinische Wochenschrift*, and his contributions to medical literature are appreciated both here and abroad. The present large volume deals with a highly important class of internal diseases, diseases which include the most largely fatal of maladies. Any new light, therefore, which is shed on this part of the medical domain must needs be welcome to the profession. And this even if, as in the present instance, the direct practical benefits to be derived from such a source are quite incommensurate with the addition to our theoretical knowledge. Not that we are inclined to undervalue the therapeutical successes obtained by the author, and perhaps equally attainable by others, but we doubt whether the general practitioner will ever provide himself with the large and costly apparatus necessary for pneumatic treatment by Waldenburg's method. Still, in the hands of specialists, the "portable Waldenburg," as we would like to call it for short, will doubtless prove an instrument of rational therapeutic efficiency and great practical utility. We have seen his latest improved apparatus in use, and have also ourselves tried it with gratifying results. But we still believe that the profession at large will not employ it. It is impossible here to do full justice to the elaborate deductions of the painstaking author. He has, we believe, fairly succeeded in his attempt to supply us with an accurate foundation to a mechanical therapy of diseases of respiration and circulation. His apparatus is so constructed that patients can inhale or exhale into a reservoir containing air which has been rarefied or compressed to any desired degree. During the process of breathing the degree of compression or rarefaction remains the same. There is also a convenient appliance for medicating the air before it is breathed by the patient. For all the minute details and necessary precautions the reader is referred to the author's 618 pages.

School and Industrial Hygiene. By D. F. Lincoln, M.D , Chairman Department of Health, Social Science Association. Philadelphia: Presley Blakiston. 1880.

This is the twelfth little volume in the series of American Health Primers, and like its predecessors it contains many practical hints and valuable suggestions, addressed to an intelligent laity. Perhaps no one subject pertaining to our general health will more amply reward the time and attention bestowed upon it, than that of school hygiene. The general principles which underly a rational management of our youth during their years of school-life are everywhere clearly stated by the author. Parents, guardians, school-teachers, and all who are interested in educational matters, will find food for thought in the pages of Dr. Lincoln's little book. Chapter VII. might, perhaps, have been omitted altogether, since the subject of the care of the eyes has been treated with the fulness it deserves by Dr. Harlan, in volume IV. of the same series of health primers.

The Nature and Treatment of Syphilis and the other so-called "Contagious Diseases." By Charles Robert Drysdale, M.D., M.R.C.P., etc. Fourth Edition. London: Baillière, Tindall & Cox. 1880.

Dr. Drysdale, without a word of explanation, substitutes the term "contagious diseases" for what we are in the habit of calling venereal diseases. In this country, at least, the profession does not limit the meaning of contagious diseases to gonorrhœa, chancroid, and syphilis. If this misnomer were the only fault to be found with Dr. Drysdale's little book of 172 pages, we would feel inclined to spend more time in the discovery of its merits. But the truth is that, after all the weeds have been eliminated, there is not much flower-garden left. We are not inclined to attempt any such undertaking, for it would prove a thankless task. His preface the author concludes as follows: "My hope is that any earnest student who does me the honor to read this little treatise will be able to *make up his mind* (italics ours) from the evidence before him, without any need of dogmatic assertions on my part." Exactly what is to become of "any earnest student" with his mind thus "made up," it is somewhat difficult to realize, unless it be that he will succumb to the contagion, and likewise try to compile a book from scattered sources without the connecting cement of personal ideas on the subject treated of.

On page 6 we learn that "in the affection called *chordee* the urethra runs along the under surface of the penis." In what affections it runs along the upper surface or elsewhere, is not mentioned. Our knowledge of pathology is enriched by the astonishing information that "the *cause* of gonorrhœa is the urethral mucous membrane being red and injected." Gonorrhœa is also a *special* inflammation, whereas we always regarded it as a specific one. At any rate, it is consoling to know that "some patients get well *in time*, who are refractory to all other influences." We believe the reader can judge from these few specimens, culled from a few pages of Chapter I., how the book is written, and what profit can be derived from its perusal.

Treatise on Therapeutics. Translated by D. F. Lincoln, M.D., from the French of A. Trousseau and H. Pidoux. Ninth Edition, Revised and Enlarged, with the Assistance of Constantine Paul. Vols. II. and III. New York: 1880. Wood's Library of Standard Medical Authors.

A large part of the second volume of this work is taken up with a discussion of the antiphlogistic treatment. The chapters display the masterly manner in which Trousseau discussed therapeutical and pathological questions. And although, as is remarked by the translator, the points involved are now somewhat obsolete, yet the pages will fully repay perusal. The remainder of the volume is devoted to the evacuants, excito-motors, and narcotics. The mode of action, and, especially, the uses of these classes of medicines, are presented in a clear and practical manner.

The third and last volume is devoted to anæsthetics, antispasmodics, neurosthenic tonics, excitants, sedatives, and anthelmintics. There is, under each head, a discussion of the general principles upon which the particular class of remedies acts. These general discussions, however, do not take up so much space as they do in the other volumes, and we find here a great deal more that is specific and practical.

The work before us gives, on the whole, a very fair presentation of the therapeutics of the present day. The physician who is looking for remedies and methods that will help him in his everyday work, can learn here the conclusions which the long experience and acute observation of Trousseau and his pupils furnished regarding the treatment of disease, and he will find these conclusions, and all that accompanies them, presented in the brilliant style of which Trousseau was so great a master. The first edition of this work was published over forty years ago, but, with the later additions, it still continues an invaluable contribution to therapeutics; and its translation into English is equally a matter of justice to its author and of practical value to the medical profession.

If we were to criticise it from a purely practical standpoint, we might object to the length of some of the discussions of general principles. The book could be used to better advantage if these were left out or condensed.

The translation seems to have been very carefully done. The index is not as complete as it might be, or as a work of such character ought to have.

* * *

Cancer in the Lower Animals.—In the *Archives of Comparative Medicine* for October is the report, by Dr. W. H. Porter, of a necropsy made upon an Oclos-Feli-Paradalis, an animal that died at the Central Park Menagerie. For some weeks it had shown signs of pain and exhaustion. On examining the abdominal cavity a cancerous growth was found involving the pancreas and omentum.

Reports of Societies.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, November 4th, 1880.

Fordyce Barker, M.D., LL.D., President, in the Chair.

Dr. Tyron, of the U. S. Navy, and Dr. Ferguson, of Troy, N. Y., were introduced to the Academy and invited to seats on the platform.

The Report of the Librarian showed that 81 bound and 16 unbound volumes, 520 medical journals, and 336 pamphlets had been donated to the library since the last stated meeting.

Dr. Paul F. Mundé then read a paper entitled

DIAGNOSIS AND TREATMENT OF OBSCURE PELVIC ABSCESS, WITH REMARKS ON THE DIFFERENTIAL DIAGNOSIS BETWEEN PELVIC PERITONITIS AND PELVIC CELLULITIS,

in which he gave a review of the differential points, anatomically and clinically, between inflammation involving only the pelvic peritoneum and inflammation confined to the pelvic cellular tissue. He was induced to bring up this much discussed question by a recent revival of the controversy as to which of these two affections was the more frequent, and the denial by Guérin, a prominent French gynecologist, that such a thing as cellulitis of the broad ligaments existed. The presence of cellular tissue between the layers of peritoneum forming the broad ligaments had recently been denied by Guérin, who asserted that he was unable to find it, and therefore corroborated the old statement of Bernutz that the evidences of inflammation and plastic exudation found in those localities were due to pelvic *peritonitis*, and not pelvic cellulitis; that the serous membrane was inflamed, not the cellular or connective tissue underneath it. Bernutz, indeed, claimed that pelvic cellulitis was a rare affection, but pelvic peritonitis a very common one.

Dr. Mundé then referred to the investigations of König and Schlesinger, Byrne of Brooklyn, Spiegelberg, and others, which proved conclusively that pelvic cellular tissue existed in abundance.

The place of election for inflammation of the pelvic connective tissue was between the layers of the broad ligaments.

With reference to differentiation between a pelvic cellulitis, an inflammation and exudation into the cellular tissue of one broad ligament and one-half of the pelvic cavity, and a pelvic peritonitis, an inflammation of the peritoneal envelope more or less covering that same pelvic cellular tissue, which also showed itself by effusion and localized swelling, he believed that the two affections were so often associated that it was impossible to differentiate between them; with an exudation into the supravaginal connective tissue there always was a plastic effusion on the surface of the contiguous peritoneum or into the adjacent serous pouch.

That was the opinion expressed by Emmet in his recent book, where he confessed his inability *ever* to distinguish between perimetritis and parametritis at the bedside, and pronounced the distinction to be merely a theoretical one.

He thought, however, that Dr. Emmet went too far upon that point, because he believed that typical cases in which the two affections could be separated existed. The etiology of the affection might, to a certain extent, aid in making a diagnosis.

The physical shock was a better criterion, for that of a large intraperitoneal effusion was vastly more severe than from an exudation into the connective tissue, which latter was often scarcely attended with fever or pain.

The physical sign, as elicited by the touch, gave the best diagnostic evidence.

As a rule, it might be held that in *pelvic peritonitis* the only distinct tumor formed was behind the uterus in Douglas' pouch; that that tumor pushed the uterus forward if sufficiently large; that it did not reach down to a level with the external os, and that in pelvic peritonitis the vaginal roof was but rarely depressed by an intraperitoneal effusion. If a lateral tumor was felt, it was only when the effusion has become so large as to exceed the capacity of the median pouch, and that lateral tumor was then always posterior to the uterus. The tumor could be felt by abnormal palpation only when very large.

In *pelvic cellulitis* the tumor was usually felt at the side of the uterus, might reach behind and below the cervix if the exudation was large enough, but then was usually as low as the external os; laterally it bulged out the anterior vaginal wall, and might also fill the whole posterior segment of the pelvic cavity; it was felt at once as soon as the inflammatory symptoms appeared, and the exudation, being confined by its surroundings, must always form a tumor. It always pushed the uterus to the opposite side, and not forward, and could usually be felt without difficulty by bimanual palpation.

In both affections the rigid exudation rendered the uterus immovable.

The practical importance of the distinction between pelvic peritonitis and pelvic cellulitis, with reference to prognosis, was very much greater than with reference to treatment. An intraperitoneal effusion was always a more serious matter, and was more liable to leave traces behind it in the shape of adhesions and obscure abscesses than a cellulitis. The prognosis, therefore, should be more guarded in peritonitis, although the majority of cases recovered. With regard to treatment, both affections were amenable to the same measures, and would show equal tardiness in recovering.

With regard to the relative frequency of the intraperitoneal and cellular effusions, he found that in over 2,000 gynecological cases of which he had accurate and full notes, there were 108 cases of distinct well-marked pelvic effusions; of those, 73 were noted as suffering from pelvic cellulitis, the precise seat and extent of the exudation being given in all, and 26 were pronounced to be pelvic peritonitis, on what appeared to be good and sufficient evidence. Of the cellulitis cases, 33 were noted as being chiefly on the left side, 21 on the right, 9 in both broad ligaments, and 10 behind and surrounding the uterus.

PELVIC ABSCESS—ASPIRATION.

Dr. Mundé then spoke of the diagnosis and treatment of a peculiar variety of pelvic abscess which he had met with several times during the past two years. By pelvic abscess he meant an abscess formed as the result of, and in an exudation of, plastic lymph in the cellular tissue of the pelvis, and in this paper he wished to refer solely to abscess of the broad ligament, in which locality all the deposits there referred to were situated. This exudation into the broad ligament (generally the left one) was bounded behind, above, and before, by the peritoneum, laterally by the uterus and pelvic wall, and below by the vaginal roof. Between the exudation and the finger was, therefore, only the wall of the vagina.

An exudation of that kind was ordinarily soft, doughy during the first few days; but it soon hardened and lost the tenderness which it at first had to a high degree. In seven of his cases the disease took a different course from the usual, and another method of treatment was finally employed. In all those seven patients all the ordinary remedies failed to dissipate the exudation, although faithfully and persistently employed for months. The patients all came under his care after they had been under other medical treatment. In all the cases there was a large solid tumor at the side of the uterus, filling up one-half of the pelvic cavity and reaching deep down to the pelvic floor, and distinctly palpable by bimanual examination. The histories of the seven cases were then read. The special method of treatment mentioned was aspiration for deep-seated pus.

The special points which he emphasized in his paper were: (1) the anatomical and clinical difference between pelvic peritonitis and pelvic cellulitis, and the very frequent impossibility of distinguishing between the two affections, for the very simple reason that they were often combined; (2) the possibility of suspecting the existence of serum or pus in an intrapelvic exudation, by reason of the long unchanged continuance of that exudation, its rounded outline, uniformly boggy feel, or the presence of occasional softer indentable spots; further, by the constitutional symptoms, such as anæmia, cachexia, perhaps rigors; (3) the safety with which such chronic lymph-exudations could be punctured and aspirated; and (4) the rapidity and certainty with which the removal of even *very small* quantities of clear serum or pus from such exudations, by means of the aspirator, was followed by complete absorption of the mass, and a return of the patient to health and strength.

He stated most emphatically that he meant only the old, chronic, stationary deposits (the very chronicity of which called for interference) which he would aspirate and expect to benefit thereby. The puncture of a fresh exudation and the removal of a greater or lesser amount of clear serum, as recommended by Brickell, of New Orleans, he considered a decidedly risky proceeding, and one that he would almost invariably expect to see followed by a fresh exudation.

He could scarcely be impelled to use the aspirator (special indications of early suppuration excepted) under two months after the beginning of the attack, since he had seen so many of these large deposits, which seemed destined to suppuration, melt away, or shrink and contract under steady, hot applications and tonics, after two or three months. Hard, contracted, fibroid lymph-deposits were therefore not fit subjects for aspiration.

The dangers of this aspiration he believed to be very slight. Indeed, he had, in several cases in the dispensary, plunged his small hypodermic needle into a pelvic exudation where he suspected pus, and found himself mistaken, without the slightest reaction. A proper amount of caution and rest afterward, should, however, always be enjoined.

In choosing the spot through which to aspirate, the most dependent, most boggy part should be selected, where the finger could indent the tissue, and the needle should be thrust in at least an inch, until either a cavity has been reached, or there was danger of piercing the whole mass. To simplify the operation, also, and chiefly because he feared that thick pus would not escape through the ordinary fine hypodermic needle, and thus the diagnosis fail, he had a slender needle, 10 centimetres (4 inches) long, made, which had about double the calibre of the ordinary hypodermic needle. In that respect the needle was like any aspirator needle of corresponding size, but he had the attachment made to fit both a hypodermic syringe and a larger glass syringe holding 20 grammes (4 oz.). He was thus enabled, first, to aspirate the mass with the long needle and small hypodermic syringe, and fluid having been found, remove the hypodermic, attach the large syringe, and withdraw the fluid. If its quantity exceeded the capacity of the syringe, he had merely to close the stopcock attached to the removable nozzle, detach the syringe, empty it, push forward the piston and reattach it, open the stopcock, and withdraw the rest of the fluid. Air was thus effectually prevented from entering.

In his treatment of aspiration of obscure pelvic abscesses and indolent exudations, he was pleased to be supported by the testimony of two such competent gynecologists as Drs. Richard B. Maury,* of Memphis, Tenn., and Angus Macdonald,† of Edinburgh.

No doubt the permanent opening of such abscesses was the proper treatment if they persisted in refilling after repeated aspiration. But he should prefer the perfectly safe puncture with the Paquelin needle to the always rather hazardous free incision which might unexpectedly strike an artery, large branches of the circular being easily felt pulsating in the roof of the vagina.

Dr. Mundé then spoke of Dr. Lawson Tait's treatment of pelvic abscesses by making an incision through the abdominal wall, and remarked that that method should be resorted to only when the vaginal method failed.

The paper being before the Academy for discussion, Dr. W. M. Chamberlain directed attention to one diagnostic point between pelvic peritonitis and pelvic cellulitis that had not been mentioned by the author of the paper, and that was the location of the exudation in the cavity of the pelvis, below the level of the peritoneal plane, in cases of pelvic cellulitis. He had often recognized the extreme upward limit of the infiltration in regions clearly extra-peritoneal, and he had seen small pockets of pus in the cellular tissue in the recto-vaginal septum which had opened spontaneously or had been opened with the point of a small bistoury. The issue of some cases of pelvic cellulitis, he thought, was conclusive evidence that the disease was in the cellular tissue, and not intraperitoneal—namely, those in which an external opening occurred. (These openings occurred or were made in the line of Poupart's ligament or close to the iliac fossa, or by the side of the anus.) In all these cases the pus escaped from a cavity that was subperitoneal. He had had no experience with the method of treatment brought forward by Dr. Mundé, but did not suppose that it was mentioned because it was a new procedure; for it had been extensively discussed nearly twenty years since by Prof. Simpson in his Lectures on Gynecology, and many cases adduced, among which was that of a London surgeon, who, having made one or more such operations about 1850, had found them to be the entering wedge of a large gynecological practice.

Dr. Wm. T. Lusk expressed his appreciation of the value of the paper, and referred to the frequency with which pelvic inflammations were overlooked in general practice, because of the multitude of symptoms to which they might give rise, many of them simulating closely the symptoms belonging to diseases of various organs. For some time he had been in the habit of aspirating these tumors and, if pus was found, to enlarge the opening at once, put in a drainage-tube, and keep the cavity clean until the healing process was complete. Dr. Lusk related the history of several cases. He further remarked that he had tried simple aspiration on rather a large scale in hospital practice, and he had not been well pleased with the results. Those results, however, did not invalidate Dr. Mundé's views at all, because the results obtained in hospital could not be applied to private practice.

He regarded the fact that the abscesses in Dr. Mundé's cases were not refilled after being emptied once as the most interesting point in the paper; for, as a rule, a large abscess refills after it has been evacuated. He regarded that point as a valuable addition to our knowledge. He had heretofore supposed that, unless an abscess was opened freely, and kept clean, the healing process would not take place. It had been his practice to treat abscesses that reached above the pelvic wall by making a free incision, four or five inches in length, and had obtained satisfactory results. By simply emptying the abscess, he had seen only temporary relief afforded, but by making a free incision, and then filling the cavity with oakum, it had been rapidly closed by the process of granulation.

Dr. T. Gaillard Thomas was happy to avail himself of the opportunity to speak upon the subject, not only because of its importance, and on account of the special interest in it, but for the reason that he had been one of the earliest and most persistent workers in connection with it. He had listened with pleasure to the paper, regarded it as a good *résumé* of the subject, but certainly it contained nothing new. During the last ten years he had persistently striven, as was well known to the President, both in his writings and teachings, for the establishment of the views maintained by the author of the paper. That which had brought the question to the surface again were the views of Guérin, and those expressed by Dr. Emmet, with regard to the impossibility of making a distinct diagnosis of each of these two affections—pelvic peritonitis and pelvic cellulitis. With regard to the presence of cellular tissue in the pelvic cavity, he believed that all were unprepared to accept the claim that there was none in that part of the body.

With regard to the aspirator, it had been commonly used both as a means of diagnosis and treatment of these pelvic tumors, but that fact made the subject none the less important, nor the paper any the less valuable. He believed it to be as easy to accept the statement that there was cellular tissue in the pelvis, and also disease of that tissue, as well as the tissue which was just above it, as it was to accept the statement that there were two tissues in the lung, the one belonging to the lung proper and the other consisting of its serous covering the pleura; that each could be diseased and that a differential diagnosis could be made between pleurisy and pneumonia. Not that one disease, in most cases, existed without the other entirely, but pursued their course as did pericarditis, which rarely terminated without affecting the cardiac muscle and developing myocarditis. He maintained that there was no reason for confounding the two affections, because pleurisy and pneumonia commonly existed together. In many cases it was exceedingly difficult, if not impossible, to separate them positively by either physical examination or clinical history, or both combined; but that was no reason for not separating them and studying them as two diseases.

---

* The St. Louis Courier of Medicine, January, 1880.

† The Edinburgh Medical Journal, June, 1880.

The same was true of pelvic peritonitis and pelvic cellulitis, and there was a large number of typical cases in which the merest tyro could distinguish between them. He thought that we were taking a step *backward* if we confounded these two diseases one with the other. On the other hand, he believed that we were going a little too far in diagnosis when we found so many cases of pelvic cellulitis.

Since the appearance of Dr. Emmet's opinion upon cellulitis, it had become very customary for diagnosticians to declare, in cases where pelvic pain existed without apparent, or rather discoverable cause, that this disease existed. Dr. Emmet's views had been misconceived, and we were, he thought, drifting into mysticism in diagnosis in reference to an important affection, the physical signs of which were very plain.

Again, while he believed that there was a pelvic disease to which the name of pelvic cellulitis had been given, he doubted whether it could be called an advance to classify under that head those cases in which there existed neither the rational symptoms nor the physical signs of the affection.

With regard to treatment, he would make the rule, "*Let pelvic effusions alone whenever and wherever you can.*" Do not use the aspirator. Do not evacuate the accumulation. It was a well-known fact that every now and then a different plan had been brought forward for the management of nearly all diseases. Only a few years ago it was suggested and carried into effect, that the proper method of managing pelvic hematocele was to open the tumor; but he presumed if there was any point fixed, at the present time, with regard to the treatment of pelvic and uterine diseases, it was that pelvic hematocele should be let alone just as long as possible. But when symptoms were developed which made it evident that the patient would die if left alone, then act promptly and at once. So he would say, with regard to pelvic effusions, he had opened many of them, and aspirated many of them, and had regretted so doing in many cases. So much in a general way upon the subject. To come to the paper more closely, he believed that Dr. Brickell's rule, spoken unfavorably of by Dr. Mundé, was a bad one. It was in violation of the rule which he had just given, namely, let pelvic effusions alone whenever and wherever you can. He also believed that if two or three months had passed and the patient showed symptoms of septic absorption, and those symptoms did not disappear promptly, the accumulation should be treated as we were occasionally obliged to treat abscesses in other parts of the body, especially in the pleural cavity. He who would draw off a pleuritic effusion within three weeks was a dangerous man; and he who would leave it for three months was also a dangerous man. After a certain length of time has elapsed, and the patient did not get well, do with it as should be done with an accumulation of fluid in the pleural cavity.

As to the method of removing the fluid he looked upon the use of the aspirator in the treatment of purulent pelvic effusions as an unsurgical procedure. It was an excellent means where a first-class surgical procedure could not be adopted. Under such circumstances he used the aspirator. While in the evacuation of fluid accumulations in other parts of the body he regarded the aspirator as an invaluable resource, he looked upon it as often an unsurgical and hazardous one when used for purulent accumulations in the pelvis when their location, and even their very existence, was a matter of doubt. He used it as a means of diagnosis, and in tentative treatment, when he did not dare to resort to better surgery. But when the tumor was within reach, and he felt that it was safe to evacuate its contents, he then resorted to the following method: Place the patient upon her side, introduce a Sims' speculum, carry in an exploring needle and move it about until pus is seen flowing through its gutter, and then, with a small pointed bistoury in the gutter of the needle, enlarge the opening, evacuate the pus thoroughly, keep the opening free by means of drainage-tubes, and cleanse the cavity regularly with a solution of carbolic acid. Such a procedure he had found more satisfactory and less dangerous than the use of the aspirator. The aspirator had been used frequently through the abdominal walls, and with disastrous results, as was well known; for the fatal cases were abundant, thus showing that it is not so safe an instrument as it appears to be. Dr. Thomas then referred to a fatal case recently reported in the Boston *Medical and Surgical Journal.*

Dr. W. Gill. Wylie had had several of these cases under his care within the last six or eight months. The first was one in which the abscess was between the uterus and the rectum. He aspirated it, the abscess refilled, an opening was then made with a knife, but the patient died.

In the *second* case he aspirated the abscess twice, and the patient recovered. Aspiration, however, was followed by a curious accident, namely, labor-pains, which caused spontaneous expulsion of a fibroid, together with a large quantity of pus.

In the *third* case he attempted to wash out the uterus, but the water did not return. It was evident that severe inflammation existed somewhere, but no evidence of pus could be obtained by physical exploration, although the constitutional disturbance indicated its presence. It was thought that signs of pus in one or two indurated masses were obtained and an aspirator needle was introduced, but no pus was withdrawn. An abscess finally opened into th bladder, and daily pus was discharged from that organ. He had seen aspiration done several year ago, and he had also resorted to it several times In one or two cases he had tried to use the needl attached to a syringe, but found difficulty in managing the needle and using the syringe at the sam time, and since then had used a short needle with supple tube. He believed that there were two diseases, pelvic peritonitis and pelvic cellulitis, although there were many cases in which a differential diagnosis could not be made either by physica signs or the history of the case. He also referred t pressure as a means for reducing indurations in th pelvis which were not sensitive, and thought it coul reach some cases which could not be cured by blistering and the use of hot water.

Dr. Frank H. Hamilton was surprised that th existence of subperitoneal areolar tissue in the pelv should be denied. He had had to deal with a fa share of pelvic abscesses, and he believed he would sustained by all general surgeons in the statemen that the vast majority of these cases came to a su cessful termination without surgical interferenc Not that interference might not be desirable, but th they took care of themselves before fluctuation w detected, and discharged either into the vagina or t ectum, or the bladder, or in other directions. He was very sure that the surgeon who searched for unknown pus in the pelvic cavity would often do more harm than good.

Dr. A. C. Post referred to a case which illustrated the fact that sometimes unpleasant consequences followed aspiration through the abdominal walls. The result was the formation of a fecal fistula.

Dr. R. Tauszky spoke of the anatomical relations, and the difference between the peritoneum and the cellular tissue of the pelvis. He had used the aspirator in four cases, besides the one mentioned by Dr. Mundé, and with good results.

Dr. Mundé remarked that he knew very well that his paper did not contain anything new, and that he stated distinctly that it was brought out entirely by the supposed new discoveries of Guérin and the statements of Dr. Emmet.

He wished simply to revive the subject before a non-gynecological audience. He agreed with Dr. Thomas with regard to letting pelvic cellulitis alone, but did not see why it was wrong when pus was found to let it out. Judging from the results obtained in the cases in which he had aspirated he believed that he did right in evacuating the pus, and the patients recovered without the slightest unfavorable symptom. It was in the cases of pelvic cellulitis, in which there was a large exudation that remained unchanged for months despite all treatment, and the patient was in a cachectic condition, that seemed to depend upon the pelvic exudation, that he recommended the plan of treatment described. Was it not proper in such cases to introduce an aspirator-needle to see if pus existed, and if it was found, was it not proper to evacuate it? To aspirate an intra-peritoneal tumor he regarded as a dangerous procedure. He was equally surprised with Dr. Lusk that the abscesses did not refill, but still the fact remained that there was no reaccumulation of pus. Of course, if the abscess refilled, and he knew that pus was present, he would not again aspirate.

For himself, he had always hesitated with reference to using a knife in the pelvic cavity. The objection which Dr. Wylie had offered to the syringe Dr. Mundé accepted as a good one. But his suggestion with reference to treatment by pressure was not new, and had been long practised by Dr. Bozeman and others.

Dr. Hamilton said that he did not say he would not open the cavity if he discovered the existence of pus.

Dr. Thomas remarked that his rule was simply to leave the abscess as long as possible; but when the time came that the surgeon could be certain that pus existed, the abscess should be evacuated, but not by means of the aspirator.

◆

Scarlatina from American Hams.—American hams are having a hard time of it. They have already been credited with causing trichinosis, anchylostosis, and hydatids. Now it is asserted that they may convey scarlet fever. A family near Chester, England, consisting of father, mother, and six children, ate American ham one day, and within forty-eight hours were all down with the scarlet fever. The fever was preceded with vomiting and purging. An infant which took no ham was the only person in the house that did not get the fever. All the patients recovered. The inferences drawn from the case are not to be accepted without a good deal more investigation.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, November 11, 1880.

Dr. T. E. Satterthwaite, President, in the Chair.

FUNGI IN SYPHILIS.

Dr. Berman, of Baltimore, by invitation exhibited under the microscope a fungus net-work in the lymphatics and blood-vessels of the neighboring tissue of a preputial chancre, and which he believed to be peculiar to syphilis. Associated with the condition he claimed that there was an infiltration of small cells, together with the bacteria described by Klebs.

Dr. Keyes did not think that the subject would be ready for discussion until additional evidence had been given by Dr. Berman regarding the claim that the fungus was peculiar to syphilis. For instance, it would be necessary to prove that the fungus existed in all the secondary lesions known to be contagious, that they were never absent in such lesions, nor in the chancre itself; that they never occurred in any ordinary ulcerations; and finally, that they were the elements of contagion. There was no doubt that the contagion of syphilis was due to a virus, but whether chemical or organized had not yet been demonstrated even by Klebs.

Dr. Otis agreed with Dr. Keyes in regard to the inadvisability of discussing the subject before additional investigations had been made. He did not think that anything had been shown by the gentleman presenting the specimens to prove that the fungus was dependent upon the syphilitic poison.

Dr. Briddon asked if any investigations had been made by Dr. Berman tending to fix the limit of time during which the fungi were confined to the initial lesion.

Dr. Berman had not yet had the opportunities for making such observations.

Dr. Tauszky referred to the investigations of Lostofer in regard to the supposed syphilitic corpuscle, and how, finally, the same appearances, supposed to be characteristic of syphilis, were found in the blood of persons suffering from scrofulous and tuberculous diseases.

Dr. Satterthwaite remarked that it was very easy to criticise such work. He did not suppose any one knew how difficult it was to investigate the question of vegetable germs unless they had tried to do so. Every step was attended with danger. For instance, the first difficulty with which to contend was the fact that almost all the specimens we were called upon to examine were filled with different varieties of germs. It was true that Dr. Berman had shown some rod-like bodies that were yoked together in a peculiar if not unique manner, but their general character could be studied only on a large scale and under different conditions of preparation. Thus, a great deal depended upon the character of the staining used, it being well known that nitrate of silver, for instance, would, of itself, produce some remarkable microscopical appearances. Again, the rod-form of fungus was particularly common, and presented many varieties.

On motion of Dr. Keyes, a vote of thanks was tendered to Dr. Berman for his presentation.

CONGENITAL DISLOCATION OF THE HIP—CLEFT PALATE.

Dr. Gibney presented two living specimens, a mother and child, the former showing unilateral congenital dislocation of the hip caused by the arrest of development of the upper rim of the acetabulum, and the latter illustrating cleft palate. The interest in the cases seemed to centre in the fact that the mother, although herself subject to arrest of development, had ten children born previously without any deformity.

FOREIGN BODIES IN THE ŒSOPHAGUS.

Dr. F. V. White presented a small, irregularly shaped sharp-pointed bone, which had been dislodged from the œsophagus of a male adult by means of the parachute bristle probang. In that connection he referred to a case in which a chicken-bone was supposed to have been swallowed, and in which an œsophageal bristle probang having been introduced no bone was found, but a small portion of the mucous membrane of the œsophagus was brought away. No bad effects followed. At the conclusion of his remarks he took occasion to exhibit different patterns of œsophageal instruments from Tiemann & Co.

Dr. Briddon remarked that it was oftentimes more difficult to extract small substances from the œsophagus than larger ones, and referred in that connection to his case of swallowed shawl-pin in which the extraction of the head of the pin, which was a miniature velocipede, was attended with considerable difficulty.

Dr. Ripley did not think that the extraction of portions of the mucous membrane of either the œsophagus, urethra, or rectum was attended with any bad results. In connection with foreign bodies in the œsophagus, he took occasion to refer to a case in which a cast-iron jack-stone had been lodged in the throat of a child for two weeks. When the patient was brought to him at the end of that time it appeared to be suffering from croup. Chloroform was administered and a polypus forceps introduced, and the foreign body was seized by one of two prongs that overlaid the larynx. But the forceps slipped and the foreign body passed farther down the throat. The finger was then thrust far back into the pharynx and fortunately got behind and below the jack-stone and extracted it accordingly. He believed that chloroform was an almost indispensable adjuvant in these cases.

Dr. Satterthwaite said that not infrequently long after the foreign body had been extracted, a sensation of its presence was left.

Dr. White, by way of illustrating the point, related the case of a gentleman who had accidentally swallowed a pivot tooth, and who imagined he felt the foreign body in the œsophagus, until, after a diligent search, it appeared in the fæces.

Dr. Ridlon presented a small brass shoe-eyelet which had been imbedded for four months in the mucous membrane of the lower lid of a child four years old. Fortunately the eyelet was an old one, and its smooth side was against the ocular conjunctiva, producing little if any irritation.

TAPE-WORM AND EXTRACT OF MALE FERN.

Dr. Van Giesen exhibited a tape-worm which had been discharged from a child, twenty-one months after taking in divided doses two drachms of the extract of male fern. The interest in the case was in connection with the discussion at the previous meeting, showing how large a dose of the vermicide could be given to a child of that age with evil effect to the worm only. He also took occasion to exhibit a specimen of the fluid extract of aspidium marginale made by himself, and to compare it with that manufactured by Merck.

CONTRACTING KIDNEY AND ITS SYMPTOMS.

He also exhibited the heart, portion of the live and two kidneys, taken from a gentleman aged fort nine years, an engineer by occupation, and of ma nificent physique. The patient had enjoyed goo health until last April, when he began to suffer fro cramps in the legs. In the beginning of May he w seized with a very severe occipital headache, attende with slight nausea and some dimness of vision. compound jalap-powder was administered with considerable relief to the symptoms. His uri showed a specific gravity of 1010, and was faintl albuminous. Not enough of sediment could be o tained for microscopical examination. The patie was seen again on the 16th of May, when his rig arm and right leg were found to be numb, with lo of power in each, as noticed in a noticeably weak grasp of the right hand and a dragging of the rig foot. Another examination of the urine on the 18 showed no renal elements. On the 20th the sed ment was obtained from a comparatively large qua tity of urine, and a small amount of albumen and few hyaline and finely granular casts were discovere The specific gravity was still low and quantity urine increased, which led to the diagnosis of co tracted kidney. By the 24th of May the patie seemed to gain more control over his legs, and h headache disappeared from that time until June 3 He then went to Boston to take electrical baths, an remained there until June 24th, when he returned t his work. At this time his appetite was inclined t be ravenous. During September the urine was e amined several times, showing the same pathologic conditions already mentioned.

October 23d, for the first time, he was attacke with dyspnœa, not that usually seen in Bright's di ease but more of an asthmatic character. There wer no symptoms of heart trouble. He recovered quic ly from the attack, and had another on the 29th an 31st. After he recovered from the last attack h became unusually jolly and talkative, and an u favorable prognosis was given accordingly.

November 1st he came home at 1 P. M. and pa took of a hearty dinner. He still complained of a aching pain in the arms and legs and dimness of v sion. After his dinner he was taken with another a tack of dyspnœa, staggered across the room, fell upo the floor, and expired. At the autopsy the cadaveri rigidity was well marked. Intestines were distende with gas. The kidneys were very little larger tha the normal size. The cortical portion was markedl diminished, and presented the microscopical appea ances of chronic diffuse nephritis. The capsules wer adherent, and the organs appeared to have been muc larger and to have undergone contraction. Nume ous small cysts were scattered throughout their su stance. The liver presented the appearances c chronic hyperæmia, associated with the nutmeg co dition. In estimating the cause of the phenomen which gave rise to the paralysis he had hoped to fin some solution in the condition of the valves of th heart, but they appeared to be healthy. Thes valves responded perfectly to the hydrostatic tes The heart itself was slightly hypertrophied, and i removing it from the cadaver a rent occurred in th muscular tissue just below the insertion of the pu monary valves. The muscular tissue in the vicini was the seat of true fatty degeneration. The lung were normal, and the pericardium contained very li tle fluid. The brain was not examined.

Dr. Seguin thought it possible that the cerebra ymptoms were due to miliary aneurisms, a condition hich was often associated with that condition of idney, and which was also found coincident with a milar state of the retinal vessels.

RECURRING ASTHMA IN BRIGHT'S KIDNEY.

Dr. **Ripley** thought that recurring asthma was a ymptom which was quite common in Bright's dis- ase, in fact, it might be the only one that at first pre- ented itself. Such cases, for obvious reasons, were romptly relieved by hydragogue cathartics.

Dr. **Van Giesen** remarked that the passage of an icreased amount of urine in these cases of contract- ig kidney was not well explained.

THE SIGNIFICANCE OF POLYURIA.

Dr. **Satterthwaite** remarked it was well known iat the increased secretion of urine and the low pecific gravity of the same were more significant ymptoms of that form of Bright's disease than the resence by themselves of casts or of albumen.

Dr. **Ripley** stated that a patient might pass more ian the ordinary quantity of urine and still be suf- ering from uræmia and anasarca.

Dr. **Seguin** called attention to another quite con- ant symptom, viz., increased arterial tension.

Dr. **Satterthwaite** referred in this connection to ie frequency of hypertrophy of the left ventricle.

Dr. **Van Giesen** remarked that in these cases of olyuria the net amount of urea was less than ormal. He had tested this on one case by frequent aminations extending over a period of eighteen onths. He believed that after all the non-elimina- on of urea probably produced the morbid results.

Dr. **Seguin** stated that a great many of the symp- oms said to be due to hyperæmia were explained by ie condition of contracted kidney. For instance, e attendant arterial tension explained the frequent eadaches in connection with this form of Bright's sease. As a rule, these headaches were confined the brow, but they occasionally occurred in the cipital region.

CEREBRAL EXCITEMENT IN BRIGHT'S DISEASE.

Dr. **Van Giesen** stated that in his case the head- he was occipital. In this connection he again lled attention to the significance of cerebral ex- tement as an element of prognosis. He always nsidered it a bad sign. He mentioned a case in oint of a child recovering from scarlatinous nephritis which sudden hilarity in singing was a striking mptom. An unfavorable prognosis was given ac- ordingly. Convulsions soon after took place, and eath occurred in the course of a few hours.

Dr. **Tauszky** referred to the methods of Dr. Heitz- an in diagnosticating different diseases of the kid- y by the appearances of the fibrinous casts. These ive already been presented to the Society by Dr. eitzman.

CASTS AS PROGNOSTIC SIGNS.

Dr. **Seguin** said that casts in the urine were of emselves of little importance as bearing upon a ave prognosis, and instanced as an example the imber and variety which occur in scarlatinous ne- iritis.

Dr. **Ripley** remarked that in his experience, when the different varieties and sizes of casts were und in scarlatinous nephritis, showing the involve- ent of the entire kidney, that the prognosis was ways grave.

Dr. **Amidon** remarked that the occurrence of albuminuria by itself was sometimes explained by anæmia.

The Society then went into Executive Session.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Adjourned Annual and Stated Meeting, November 22, 1880.

Dr. A. E. M. **Purdy**, President, in the Chair.

REPORT OF COMMITTEE ON PRIZE ESSAYS.

After the reading of the minutes of the annual meeting and the report of the Auditing Committee, the Committee on Prize Essays reported that only one essay had been sent to them for examination. Its title was, "On the Benignity of the Specific Diseases, with a Tabular History of Three Hundred and Seventy-Eight Cases," by Parva Lux. The committee recommended that the prize be awarded for this essay, because it possessed "so much merit as a conscientious and laborious study of clinical phenomena, and as a valuable and important contribution of new researches and original observations, with such literary excellence in simplicity, and variety of style, and clearness of statement."

The Society adopted the recommendation of the committee, and the President then opened the sealed envelope bearing the motto "Parva Lux," and found the name of Dr. C. L. **Dana**, who was announced as the successful essayist.

On motion, the Society voted to assess each of its members the sum of *two* dollars, in addition to the annual dues, to be used for defraying its expenses for the ensuing year.

COMMITTEE ON HYGIENE—SUPPLEMENTARY REPORT.

Dr. J. C. **Peters** then read a supplementary report from the Committee on Hygiene, which dwelt especially upon the filthy condition of the streets of the city of New York and their influence in the propagation of such diseases as cerebro-spinal meningitis, diphtheria, and scarlet fever. On motion, the request embodied in the report was granted, and the committee was further requested to confer with the Society for Sanitary Reform in the City of New York, concerning the best method by which the special object of their supplementary report could be accomplished.

The President read a communication from the Committee on Law of the Board of Aldermen, asking that the Society appoint a committee to unite with a like committee from the College of Pharmacy of the City of New York, to draft an ordinance regulating the sale of poisons and poisonous drugs and medicines by apothecaries and others in this city. It was referred to the Comitia Minora, with power.

The Secretary offered a series of resolutions intended to provide for the disposal of the volumes of the Transactions of the Medical Society of the State of New York, received annually by the Society. Adopted. The subscription list will be kept open for one month.

REPORT OF THE COMMITTEE ON ETHICS.

The report of the Committee on Ethics, made at the annual meeting, was then taken up, and Dr. H. G. Piffard offered the following resolution, which was adopted:

Resolved, That the report of the Committee on Ethics be adopted, and that the Medical Society of this state be requested to revise the codes of ethics by which the profession of this state are governed.

The Adjourned Annual Meeting then adjourned.

The Stated Meeting was called to order by the President, Dr. A. E. M. Purdy, who thanked the Society for the honor of an election for a second term as its presiding officer.

The following were announced as the standing committees for the ensuing year:

Committee on Ethics: Dr. E. D. Hudson, Jr., Chairman; Drs. Jas. R. Leaming, Walter R. Gillette, Geo. T. Harrison, and Wm. F. Cushman.

Committee on Hygiene: Dr. John C. Peters, Chairman; Drs. E. G. Janeway, C. E. Billington, D. B. St. John Roosa, and A. B. Judson.

Committee on Prize Essay: Dr. Fordyce Barker, Chairman; Drs. H. B. Sands, Austin Flint, and E. Eliot.

Auditing Committee: Dr. W. M. Chamberlain, Chairman: Drs. Ellsworth Eliot and Horace P. Farnham.

On the recommendation of the Comitia Minora it was voted to grant certificates of membership to Drs. W. B. Goldsmith and E. A. Judson.

FOR THE PROTECTION OF THE CENTRAL PARK.

Dr. A. Jacobi offered the following resolution, which was seconded by Dr. Roosa and unanimously adopted by the Society:

Resolved, That the President be authorized and directed to appoint, in case of necessity and at his leisure, an appropriate committee for the purpose of defending the Central Park against any attempts to change its destination.

A communication from Surgeon and Bt. Brig.-Gen. U. S. Army. T. A. McParlin, M.D., was then read, after which the Society adjourned.

BALTIMORE MEDICAL AND SURGICAL SOCIETY.

Discussion on Urethral Stricture.

(Reported for The Medical Record.)

On November 3d the regular discussion was opened by Dr. C. F. Bevan, on

URETHRAL STRICTURE AND ITS TREATMENT BY INTERNAL URETHROTOMY.

Dr. Bevan began his subject by saying that a few years ago the answer to the question, What is the best and most proper treatment of urethral stricture? would have been something like this: To introduce a bougie, and gradually dilate the urethra till a sufficient opening should be obtained, and that a No. 8 or 10 (English) would be sufficiently large; that if the stricture should be very dense, and not readily yield to well-directed efforts at dilatation, or if the case demanded prompt treatment, then divulsion might be practised and followed up by dilatation; and that it would, in extremely few instances, be necessary to do the operation of perineal section with or without a guide; that patience and a little knowledge of anatomy would generally enable the surgeon to find the road to the bladder, in which event dilatation could be relied upon to complete the cure, and that, finally, patients the subjects of stricture were doomed to life-long urethral medication in the shape of sounds and bougies, for such contractions would always return, no matter how carefully the case might be treated.

In the last ten years these views had been energetically attacked by Dr. F. U. Otis of New York, wh
in a series of able papers, proposed new instrument
new principles, and new methods of treatment i
strictured urethræ. Dr. Otis's views had, howeve
made headway very slowly among the great body
surgeons, and are still the subjects of active, not
say acrid debate.

Dr. Bevan has operated for 225 strictures by i
ternal urethrotomy, in 100 cases, and used tho
cases as a basis for the examination of the views
Dr. Otis as proposed by himself in the last edition
his work on "Stricture of the Male Urethra." The
are: The great questions in regard to normal u
thral calibre; the definite proportionate relation b
tween the circumference of the urethra and the org
in which it is situated; the importance of recogni
ing the possibility of stricture of a calibre above t
then accepted normal standard size of the urethr
the common dependence of gleet and often of troubl
some reflex irritations upon such strictures; t
greater frequency of stricture in the anterior part
the canal; the possibility of a radical cure of stri
ture by dilating urethrotomy; the great advantag
of such operation over the dilating procedures, bo
in regard to safety, comfort, time, and permanen
of results.

The results of nearly 300 measurements of t
urethra made with the urethrometer and bulbo
sounds have convinced Dr. Bevan that the form
estimates of the normal size of the urethra, accordi
to leading English and French surgeons, were mu
too small. These estimates were No. 8 English a
No. 21 French for the respective schools. In D
Bevan's experience, the calibre of the urethra was
no instance less than No. 26 French, nor more th
No. 47 French. The latter case had been operat
upon by the late Dr. T. R. Brown, and is probab
the largest urethra on record. The average measu
ment was No. 30 French.

In the experience of Dr. Bevan the meatus is
ways the narrowest part of the urethral canal; it
often contracted when the rest of the urethra is n
mal, and it is frequently the site of cicatricial co
tractions resulting from venereal sores and oth
forms of inflammatory action. From this experien
he concludes that the rule given by Dr. Otis w
afford a more nearly correct guide to the size of t
urethra than can be found in the meatus. It m
be that with a larger experience the relationship
tween the circumference of the penis and the cali
of the urethra can be accepted as proven; at prese
it is a valuable working rule.

Dr. Bevan considers the recognition of strictu
of large calibre of great importance. The freque
dependence of gleet and of troublesome reflex aff
tions upon the contractions invading only sligh
the canal of the urethra needed no demonstratio
The sooner such contractions are recognized a
brought under treatment the better for the patien

An interesting case of purely reflex nervous sym
toms depending on stricture was related, which
briefly as follows:

A well-developed man, forty-three years old, w
suddenly seized with vertigo and cardiac distu
ance, June 13, 1879. He was seen within an ho
after his seizure, at which time most of his sym
toms had abated. He complained of headache, wh
had been quite frequent of late, and of a train
symptoms referable to dyspepsia. Physical exa
nation negative. The first clue to the cause of
symptoms was found when about to examine
urine. It was found that urination required a gr

ffort, and that the water was passed very slowly. When interrogated he admitted having had a stricure eighteen years ago, which had, however, been ured by a distinguished surgeon of New York. He aid he had never had any trouble with his urethra ince that time. On examination, a contraction, admitting a No. 10 F., was found at three inches from he meatus, and at four and a half inches another ontraction was found, admitting only a bulbous ound No. 4 F. The circumference of his penis was hree and a half inches, and normal urethral calibre, s determined by the urethrometer, thirty-four milmetres. After division of the strictures by internal rethrotomy all the symptoms of dyspepsia and his eadache rapidly subsided. He is now in perfect ealth, and a No. 34 F. bulbous sound passes to the ulbo-membranous urethra without detecting any econtraction fourteen months after the operation.

The location of the 225 strictures treated by Dr. Bevan were as follows: including contractions of the eatus there were 38 strictures in the first quarter nch, 47 between ¼ and 1¼ inches, 51 from 1¼ to 2¼ nches, 50 from 2¼ to 3¼ inches, 14 from 3¼ to 4¼ nches, 11 from 4¼ to 5¼ inches, 9 from 5¼ to 6¼ nches, and 5 from 6¼ to 7¼ inches. Out of the enire 225 strictures, therefore, 186, or 82 per cent., vere located in the anterior four and a quarter nches.

Whether stricture is ever entirely cured by any ther method of treatment than that of cutting is xceedingly doubtful. To dilate a stricture up to No. 8 or 10 English, and then send the patient away vith a sound which he must pass during the rest of is life, is certainly not curing it. On the other and, Otis, Mastin, Pease, Brown, Teevan, and others ave placed on record the results of their own expeience, and claim radical cures. Otis reports thirtyne of his first published series of 100 cases in which o recontraction had taken place in from two weeks o three years. In his second series of 136 cases, hirty-eight were examined, and no recontraction ound. Mastin claims nine radical cures out of hirty cases operated upon. Pease re-examined wenty-four out of forty-five cases, at intervals from ne month to two years, and found no recontraction. Brown makes a similar report.

In twenty-seven cases, re-examined after an interval of from four months to three years from the time f operation, Dr. Bevan found no recontraction.

It is probable that even a larger proportion is cured han is indicated by these figures, since most of Dr. Bevan's cases were dispensary patients, who would ot be likely to return unless there was trouble from recontraction.

In the 100 cases upon whom the operations of Dr. Bevan were performed, urethral fever followed in ten cases. This was limited to a chill followed by a rise of temperature from two to four degrees, which subsided in a few hours and did not return. The prophylactic administration of quinine and morphia seems to be of service.

Peri-urethral abscess occurred in one case. The section was made with a Maisonneuve urethrotome. The patient, an old subject of stricture, was seized with retention which he tried to relieve with his own catheter. He drew blood several times, and failing to introduce the instrument consulted two or three physicians without obtaining relief. Dr. Bevan was consulted on the fourth day of attack. His condition was very bad from pain and loss of rest, as well as great nausea, the result of the use of opiates. He had become very weak. A firm, painful swelling was found in the perineum. Under chloroform, a filiform bougie was introduced through the stricture with difficulty, and after it the guide of the Maisonneuve urethrotome, with which the stricture was cut to No. 8 English, and a catheter used to draw his water. Forty-eight hours after the operation the abscess was opened and several ounces of pus evacuated. The week following he was cut to No. 36 F., his normal calibre, without the slightest accident. He was re-examined five months afterward with No. 36 bulbous sound, and no recontraction found.

Acute urethritis followed in three cases, but gave no trouble.

Curvature of the penis, very annoying to the patient, resulted in one case. This passed off within three months without further treatment.

In one instance epididymitis followed the operation; the patient afterward stated that his testicle had been painful for twenty-four hours previous to the operation. No hemorrhage of consequence followed in any of the 225 strictures divided. No deaths occurred in Dr. Bevan's series of 100 cases. In one case the patient was suffering from an attack of pyelonephritis and abscess at the time of operation. The abscess discharged through the ureter and bladder, and after a serious illness of several weeks he recovered.

The suggestion of Dr. E. L. Keyes, to restrict the operation of dilating urethrotomy to the pendulous urethra, while perhaps a wise rule to follow, is of small applicability, inasmuch as from seventy-five to eighty per cent. of all strictures occur in the anterior four inches of the urethra. In the opinion of Dr. Bevan, Holt's operation (divulsion) should be absolutely discarded. It was a dangerous operation, and moreover failed to cure the stricture. The tearing of the tissues is liable to be followed by a traumatic stricture which may become very intractable in the future.

Dr. Coskery said that, notwithstanding the favorable showing made for internal urethrotomy in Dr. Bevan's paper, he was not yet ready to adopt the operation. It should be remembered that dilating urethrotomy was a very youthful operation; one that was still on trial. On the other hand, slow dilatation was safe, settled, and satisfactory. Because a child's head and body could be forced through a woman's vagina during parturition, certainly did not make it desirable that all women should have a vagina with a calibre of 4–5 inches. For the same reason, because a crowbar can be rammed down a man's urethra under certain circumstances does not make it advisable that all men having urethral narrowing should be thus treated. A urethra with a calibre of No. 8 English was large enough for all practical purposes; all that was necessary was to keep it pervious to that extent. With patience and a little knowledge of anatomy a surgeon could introduce a bougie into any opening through which water could pass out.

Dr. Lynch was disposed to look more favorably on the modification of internal urethrotomy introduced by Dr. Otis. Putting the question to himself, if he had a stricture that gave him trouble, he should certainly prefer having his stricture cut to passing a sound into his urethra daily or weekly for the rest of his life.

Dr. Erich, while believing himself possessed of the average amount of patience, was compelled to admit that he had repeatedly been unsuccessful in passing even a filiform bougie through narrow, tortuous strictures. He was not willing to accept the old dictum that where water could pass out a bougie could be passed in, as entirely true. So far as a knowledge of the normal anatomy went, it would puzzle some of the best anatomists to demonstrate a urethra in some of these specimens. A point which he had frequently noticed, and to which he was disposed to attach some importance is, that a narrow stricture might be dilated to a certain size—say to No. 5 or No. 6 English—with comparative ease; but as soon as it was attempted to go beyond that, so much tumefaction followed at the site of the stricture that at the next sitting only a No. 3 or No. 4 English could be passed, and the same tedious work had to be gone over. He decidedly preferred Otis's operation, and believed that radical cure of stricture by its means was possible.

DR. ROHÉ expressed surprise at the reactionary views of Dr. Coskery. Dilatation could certainly not be so safe, rational, and satisfactory a procedure as had been claimed. It was less than ten years since Dr. Otis had presented his novel views on these subjects. During this comparatively brief period the operation of dilatating urethrotomy had been performed perhaps 1,500 times. Surely such popularity could not have been won in face of an established procedure if this had been so reliable and satisfactory as Dr. Coskery claimed for life-long dilatation. Dr. Otis's operation was on trial, it was true; but it was a trial that seemed to be eminently satisfactory to both surgeon and patient wherever it had been adopted. It was worthy of note that the greatest opponents of dilating urethrotomy were those surgeons who had not tried the operation, while those who had once tried it were almost without exception strenuous advocates of it.

Correspondence.

THE SALE OF POISONS.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR—Referring to your article on the sale of poisons in your issue of the 20th instant, I cordially indorse Dr. Peters' suggestion that patented and proprietary articles, such as soothing syrups, cough mixtures, etc., should have *poison* labels upon them.

Many of the pills advertised for the cure of constipation, headache, biliousness, and liver complaint ought to be labelled in the same manner. "The Little Giant Pill" so extensively advertised and sold in the New England States, especially in New Hampshire and Connecticut, contains in each pill ¼ gr. each of ext. belladonna and ext. nux vomica, and serious consequences may be apprehended from the sale of such a remedy.

SMILAX.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from November 21, 1880, *to November* 27, 1880.

HOFF, J. V. R., Capt. and Asst. Surgeon. Granted leave of absence for one month. S. O. 208, Department of the East, November 26, 1880.

WOMAN'S MEDICAL COLLEGE, NEW YORK.—Dr. Charles L. Dana has been elected Professor of Physiology in the Woman's Medical College of this city.

Nov. 27, 1880.	0	10	110	4	16	122	3	0

THE ANNUAL MEETING OF THE TRI-STATE MEDICA SOCIETY of Kentucky, Illinois, and Indiana, was hel November 9th, 10th, 11th, and 12th, at Louisvill Ky., "the metropolis," as one of the speakers said "of a people known the world over for possessin and producing the greatest comforts and delights c life—Kentucky tobacco, Kentucky horses, Kentuck whiskey, and Kentucky women."

The hospitalities of the city were bestowed lavishl upon the visitors, many excellent addresses wer made, and a large number of papers were read.

AN ADJOURNED MEETING OF THE STATE BOARD O HEALTH was held in this city November 27th, to consider the matter of its annual report. A resolutio was passed declaring a nuisance certain ponds mad stagnant by railway embankments at Hart's Falls.

The topics to be presented in the annual repor are: the organization of local health boards; the organization of methods for repressing contagious an malarial diseases; sanitary surveys; the manner i which our average population is domiciled, etc.

In regard to the organization of local health boards not much progress can as yet be reported. Ther are in the state 930 townships, 330 incorporated villages, and 24 cities, each one of which is entitled b law to a board of health. There are, in fact, no one hundred local boards in actual operation. It i too soon, however, to expect very much in this direction.

TRYING TO RESUSCITATE A GUILLOTINED HEAD.—Immediately after the decapitation of the murdere Ménesclou, in Paris recently, the body was taken t the School of Medicine for examination. The hea had been severed from the body by a clean cut, th knife having passed through the neck just below th vocal cords. The face was calm and presente nothing particular. M. Dassy, preparator of anatomy, injected into the carotid artery some bloo taken from a live dog. The face of the decease became immediately flushed, and the lips reddened it was expected that some emotional movements o the muscles of the face would take place; but, owin to a misunderstanding, the body had not been give up till five hours after death, which of course interfered considerably with the experiment and mad the results incomplete. However, M. Sappey wa enabled to perform certain interesting experiment on the different muscles of the face by means o electric currents.

Prevalence and Cause of Typhoid Fever.—The nglish journals report an unusual number of outreaks of typhoid fever during the present fall. ome of them have been very severe. They have ocirred for the most part in small rural communities, hose systems of excrement disposal is by pit-privs, and whose water-supply is derived from wells ig in the vicinity of the houses, and, therefore, of ie privies. There is usually no history of any preous case before the outbreak begins; and, unless ie latter is to be accounted for on the pathogenetic ieory, which does not receive general acceptation, ie reason for the outbursts, says the *British Medil Journal*, must be found elsewhere. The most atural explanation would seem to be that which sts upon the presence of old germs of the disease ing latent in the soil. The prolonged drought, ich as England experienced last summer, dried the ibsoil and sunk the level of the water in the wells. eavy rainfalls in the autumn then came and rapidly ercolated through the soil into the wells, carrying iere the infective germs. Such a theory as this is iought to be more rational than to suppose that the isease has arisen *de novo.*

The Harveian Lectures for the coming season re to be delivered in December, by Dr. James E. 'ollock. Subject: "On the Prognosis and Treatient of Chronic Diseases of the Chest in Relation to Iodern Pathology."

Effects of Long-continued Lactation upon the 'varies and Uterus.—Dr. W. Japp Sinclair relates number of cases from whose histories he considers ie following conclusions may be presumed to be ue:

1. Lactation tends to prevent conception by its ifluence on the ovaries in retarding their return to ie state in which ovulation is perfect.
2. After weaning, the evolution of the ovaries becomes more rapid than it is during any period of ictation.
3. After long-continued lactation, its sudden cesation is liable to be followed by a rapid evolution of ie ovaries and uterus, giving rise to symptoms of varian and uterine hyperæmia.
4. Long-continued lactation may cause superinolution of the ovaries and uterus, resulting, under ivorable circumstances, in complete or partial proipse of the uterus.

Clinical Study in American Medical Colleges. -A correspondent of the *Lancet* writes from Philaelphia, concerning the Philadelphia hospitals, as ollows: "The total absence of clinical clerks and ressers could hardly fail to be remarked, the house urgeon's assistant taking the form of a four-wheel o-cart fitted with every requisite. Clinical study in he medical curriculum is apparently unnecessary. was assured that at Jefferson College, which is one f the leading medical schools in the country, a man ight take his degree in medicine and go forth to ractice his profession *without ever having seen a ase!*"

Phthisis and Dampness of the Soil.—The invesigations of Dr. Bowditch and Dr. Kelly, which eemed to demonstrate the causal relation between hthisis and dampness of the soil, have been recently isputed by Dr. Charles Kelly, health officer of West ussex, England. He gives a table showing the geoogical formation of the soil in the different districts nd the corresponding mortality from phthisis. In this it is shown that there are more deaths in the dry districts than in the moist. Dr. Kelly seems to have considered any outside factors that might modify his conclusions. The question evidently needs further study.—*Brit. Med. Journ.*

Castration of Dogs.—It is estimated that sheep to the value of $30,000 were killed by dogs in Kentucky in 1879. It is claimed (*Archives of Compar. Med.*) that castration prevents this tendency to kill sheep.

The Sudden Death of Dr. Louis Presse, of Paris, is announced. Dr. Presse was an eminent *littérateur* and medical journalist. He contributed especially to the *Revue des deux mondes* and to the *Gazette médicale.*

Treatment of Sea-sickness.—Nitro-glycerine in doses of gr. $\frac{1}{100}$ to gr. $\frac{1}{300}$ is highly recommended for sea-sickness by a correspondent of the *British Medical Journal.* In the same paper Dr. R. Bruce Low states that after long experience with many kinds of remedies he has settled down on drachm doses of bromide of potassium as affording the surest relief.

Influence of Music on the Circulation of the Blood.—Dr. Dogiel has made some studies on this subject, from which he concludes: (1) That music has an influence on the circulation of the blood. (2) That it sometimes raises and sometimes depresses the blood-pressure. This influence is brought about by the reflex action of the excited auditory nerve upon the medulla oblongata. (3). Generally the heart beats faster, the automatic motor ganglia being stimulated. (4) Strychnia increases the effect of music; curara lessens it. (5) The effects vary with the pitch, loudness, and tone of the music.

Removal of Three Ovaries.—In the *Allgemeine Wiener medizinische Zeitung* (No. 36) is a short notice of an ovarian operation performed by Dr. Fritz Keppler, a German physician settled in Venice, which was undertaken for the purpose of removing what appeared to be ovarian and tubal degenerate growth on both sides. In the course of the operation, however, it appeared that there was a fully formed third ovary and tube, which were also the seat of disease, so that it was necessary to perform extirpation of the three ovaries and three tubes. Such an anatomical anomaly is, it is stated, previously unknown; so that the case is one of great anatomical as well as surgical interest. The operation was entirely successful.—*Brit. Med. Journ.*

Stramonium-Poisoning and Stammering.—Dr. J. H. Straughn, of Lexington, Mo., writes: "Some time since I had a case of stramonium-poisoning in a child —gave an emetic and a purgative, and used morphia hypodermically; child made, as I thought, a perfect recovery; but I have recently learned that she *stammers badly,* something she never did before the poisoning."

The New York Society for the Relief of Widows and Orphans of Medical Men held their thirty-eighth annual meeting on the evening of November 24th, Dr. S. T. Hubbard in the chair. The laws governing this society entitle the widow of a member to $400 per annum, but for every $10, or multiple of $10, of income possessed by the widow, an amount equal to fifty per cent. of said income must be deducted from the annuity, and an orphan is entitled to $100 per annum, subject to like conditions. The earnings of a widow or of the children by their own industry are not considered as income subjecting the annuity to deduction. In special cases the aged father, the widowed mother, or aged sister of a deceased member who had been dependent upon him for support may receive assistance at the discretion of the Board of Managers, or by a three-fourths vote of the members. The society numbers 150 members. The Treasurer's report showed the total assets of the society to be $129,825.05. The receipts during the past year were $10,727.72, and for the same period $4,618.75 was paid out in annuities, and $115.80 for miscellaneous expenses. The following officers were elected: *President*—Dr. Willard Parker; *Vice-Presidents*—Dr. Jared Linsly, Dr. Isaac E. Taylor, and Dr. S. S. Purple; *Treasurer*—John H. Hinton; *Managers*—Dr. S. T. Hubbard, Dr. William Detmold, Dr. Charles Wright, Dr. John G. Adams, Dr. J. Wiener, Dr. William N. Blakeman, Dr. E. C. Seguin.

Small-pox is committing dreadful ravages among the Indians who people the sparsely settled districts on the north shore of the Gulf of St. Lawrence. Information recently received by the Canadian government shows that they are dying by hundreds. A panic has seized the survivors and they have fled from the dead and dying, leaving the former unburied and the latter uncared for, to seek refuge in the woods, where their trails are marked by lines of corpses. The worst feature of the case is that when a doctor was sent by the local authorities to relieve the condition of the distressed savages, it was found that he was a political opponent of the Board, and he was at once recalled, and the panic-stricken district left to itself until a medical man of their own political stripe can reach it.

A New Hypodermic Syringe.—Dr. W. R. Leonard writes: "In the Medical Record of Nov. 20th, p. 587, you mention a new hypodermic syringe by Dr. John M. White, of Pleasant Ridge, Ala. Allow me to draw your attention to the fact that such a syringe as described by Dr. White has been in use for the last eight years, was published in the *New York Medical Journal* for October, 1876. It is illustrated on page 901 of Shepard & Dudley's illustrated catalogue of surgical instruments."

Alms-House Hospital, B. I.—Warden Vought, of the Alms-House, Blackwell's Island, has just fitted up a beautiful new dispensary for the occupancy of the Resident Medical Staff of the Alms-House Hospital, thus supplying a long-felt want.

Ocular Defects and Constitutional Diseases.—Dr. George T. Stevens writes: "In his recent card Dr. Roosa fully confirms the statement made in my note of November 6th. The point to which I call attention of the readers of the Record is, that a lecturer who attempts to convince his auditors and readers that views advanced by myself 'are probably not founded upon accurate observations,' while he utterly fails to establish even a fair ground of suspicion against me in this respect, actually convicts himself of 'inaccurate observations' in regard to the central case of his lecture. The case which, he says 'has induced me to speak to you on this subject.'

"In the lecture, the author starts upon indirect authority, that in the case reported the headaches had been 'attributed to a want of co-ordination of the internal recti and . . . . . it was now advised that the *external recti be cut*.'

"He now publishes an extract from a letter from his informant in which it is stated that 'Dr. Stevens proposed the same operation that he had performed on his cousin. I understood this to be *partial tenotomy* of *internal rectus of one eye*.' Now, as Dr. Roosa has introduced a second case in order to show that I have performed a certain operation in one case and might in another, it may be of interest to know what he does not state. That the cousin to whom he refers, has, during the year which has passed since the operation referred to, enjoyed a degree of health to which she had previously been a life-long stranger, and that whereas she had from early childhood suffered from neuralgic headaches of most intense character, occuring so frequently as clouded her whole life, she is now free from her terrible attacks. It may also be a matter of interest that in respect to all the tests of muscular power spoken of in Dr. Roosa's lecture, the cases of the two cousins were, to a singular degree, alike.

"It is not my purpose here either to discuss the peculiar logic of Dr. Roosa's lecture, nor to present new evidence regarding the value of my own views In due time, however, I shall present many instances in which tenotomy, more or less complete, of the internal rectus has been performed with the most marked beneficial results in cases in which the muscular relations have been similar to those in the cases spoken of by Dr. Roosa."

Poisoning by Ergot.—Dr. M. F. Leary, of Gaylord, Kansas, writing to Dr. J. M. Keating, of Philadelphia, says: "Referring to your articles in the Record of October 18th and November 13th, and Dr. Radcliffe's criticism on your diagnosis, I beg to state that some two years since I had about the same experience with ergot that you have detailed The case was in my own practice, *a case of miscarriage*, and when everything was doing nicely, ℥ss. o 'Squibb's' ergot was given by error, ʒj. every half hour, followed by an alarming collapse and symptom much resembling those observed in your case. Sinc seeing your article I have written the case up an sent it to the *New Orleans Medical and Surgica Journal*, believing that this drug is more dangerou than commonly supposed. I can find but one othe instance on record of poisoning from ergot. In my own case I am satisfied there was neither hemorrhage, shock, nor idiosyncrasy at work, but purely case of poisoning from ergot."

Dr. C. R. Agnew has been chosen to fill the vacancy in the State Electoral College.

Philadelphia's Coroner.—Dr. W. S. Janney wa made Coroner of Philadelphia at the recent electior This makes the third medical incumbent of this offic as Dr. Janney's predecessors were Drs. Kingsto Goddard and W. Kent Gilbert. The politicians a last seem to recognize the fact that no one but physician can be acceptable to the voters.

CARTWRIGHT LECTURES,* ON THE PHYSIOLOGICAL ANTAGONISM BETWEEN MEDICINES, AND BETWEEN REMEDIES AND DISEASES.

By ROBERTS BARTHOLOW, M.D.,

PROFESSOR OF MATERIA MEDICA AND THERAPEUTICS IN THE JEFFERSON MEDICAL COLLEGE, PHILADELPHIA.

(Special Report for The Medical Record.)

Lecture IV.

CHLORAL AND STRYCHNIA—CHLORAL AND PICROTOXINE—CHLORAL AND ATROPIA—OPIUM AND VERATRUM VIRIDE—OPIUM AND GELSEMIUM—OPIUM AND ACONITE—MORPHIA SUBCUTANEOUSLY AND CHLOROFORM BY INHALATION, ETC.

The discovery of chloral hydrate and of the antagonism between this agent and strychnia by Liebreich are followed by a vast number of researches upon the subject, and the literature of chloral accordingly has already become enormous. As we are concerned at present only with the antagonisms of chloral, however, I shall confine myself to what has been accomplished in the elucidation of these. In the first place, Liebreich demonstrated that animals which had been thrown into a deep stupor by lethal doses of chloral were aroused by the administration of strychnia, which thus proved the means of saving their lives. Again, if a lethal dose of strychnia were given to two rabbits, and to one of them fifteen grains of chloral were given in addition, the one which received the strychnia alone would die in tetanic convulsions in the space of ten minutes, while the other would sink into a quiet sleep, lasting perhaps a couple of hours, from which it would awake in the same condition as before either agent was administered. Such a striking experiment would seem to afford conclusive evidence of the existence of the antagonism between chloral and strychnia; but the results of the researches of Liebreich have been abundantly confirmed by the labors of other observers, and especially by the exhaustive investigation of the subject undertaken by the committee of the British Medical Association, of which Dr. J. Hughes Bennett was chairman. The conclusions which they reached were as follows:

"(1.) That after a fatal dose of strychnia, life may be saved by bringing the animal under the influence of chloral hydrate.

"(2.) That chloral hydrate is more likely to save life after a fatal dose of strychnia than strychnia is to save life after a fatal dose of chloral hydrate.

"(3.) That after a dose of strychnia, producing severe tetanic convulsions, these convulsions may be much reduced, both in force and frequency, by the use of chloral hydrate, and, consequently, much suffering saved.

"(4.) That the extent of the physiological antagonism between the two substances is so far limited that a very large fatal dose of strychnia may kill before the chloral has had time to act, or so large must be the dose of chloral hydrate to antagonize an excessive dose of strychnia that there is danger of death from the effects of the chloral hydrate.

"(5.) Chloral hydrate mitigates the effects of a fatal dose of strychnia by depressing the excess of reflex activity excited by that substance, whilst strychnia may mitigate the effects of a fatal dose of chloral hydrate by rousing the activity of the spinal cord; but it does not appear capable of removing the coma produced by the action of chloral hydrate on the brain."

Husemann, who made a careful investigation of the antagonism supposed to exist between chloral and strychnia, holds that the former is an antidote to the latter, overcoming the spasms and preventing death, and that it acts in the same way in regard to the strychnia-basis known as brucin.

(Having alluded to the experimental researches concerning the antagonism conducted by Rajewski, Erlenmeyer, Arnould and Oré, the lecturer proceeded to discuss the results obtained from clinical experience.) I have found seven cases of strychnia-poisoning in which chloral was the principal or only agent employed in the treatment, and they were all successful. I have also found severe cases of strychnia successfully treated by chloroform-inhalation, and if we accept the view of Liebreich that the effect of chloral is due to the disengagement of chloroform in the blood, these will afford additional and confirmatory evidence as to the reality of the antagonism. I have been unable to find any instances of chloral-poisoning in which strychnia was adequately employed as an antidote. In summing up the evidence we are forced to conclude that chloral hydrate and strychnia are antagonistic; but at the same time it is true that chloral is an antagonist to strychnia-poisoning rather than that strychnia is an antagonist to chloral-poisoning. In the treatment of the toxic effects of strychnia by chloral, the doses of the latter employed should depend upon the symptoms observed. Sufficient chloral should always be given to put an end to the spasms caused by the strychnia, in order to prevent a stoppage of the respiration through fixation of the respiratory muscles, which is one of the chief dangers to be apprehended. The amount will vary according to circumstances. In the case of a Sioux Indian treated by Dr. Turner, 105 grains of chloral were given within four hours. The quantity of strychnia taken could not be ascertained; but the chloral was kept up until there was no tendency to a return of the spasms.

When strychnia is used in chloral-poisoning, the object is to overcome the tendency to failure of the heart and respiration by stimulating the cardiac and respiratory centre, and the doses required are probably considerably less than would be supposed theoretically. About one-sixtieth of a grain should be given at first, and after that one one-hundred-and-twentieth of a grain repeated every half-hour until the maximum is approached.

Let us now consider the mechanism of the antagonism between chloral and strychnia, and in order to do this we must understand the physiological action of each. Chloral, with or without a brief stage of excitement, produces sopor closely resembling natural sleep, and in lethal doses, coma and insensibility. In toxic doses, therefore, it suspends the cerebral functions. It acts in like manner on the spinal cord, preventing reflex action and motility, although it does not interfere with sensibility until the cerebral functions are suspended. It enfeebles the heart's action, reduces the arterial tension, and lowers the temperature to a considerable extent. Under its influence respiration becomes gradually slower and more shallow, and is finally arrested. Death takes place either from paralysis of the heart or of the respiration, or may be due to the arrest of both the circulatory and respiratory functions simultaneously.

---

* Of the Alumni Association of the College of Physicians and Surgeons, New York.

Strychnia, on the other hand, does not affect the cerebral functions at all, but acts energetically on the spinal cord. It exalts its reflex irritability, and is a motor excitant. It also has the effect of stimulating respiration, strengthening the heart's action, and raising the arterial tension. Chloral and strychnia can hardly be regarded as antagonistic in their effects on the cerebrum, since the former suspends its functions, and the latter does not affect it in any way; but in regard to the spinal cord, their antagonism is very complete, strychnia exalting its functions and chloral interrupting them. Thus, by stimulating the respiratory and vaso-motor centres in the cord, strychnia counteracts one of the chief dangers from chloral narcosis. The great danger from strychnia is tetanic fixation of the respiratory muscles, and this is obviated by the action of chloral. This antagonism is more complete than the opposite one. Whence it follows that chloral is more useful in strychnia-poisoning than strychnia in chloral-poisoning.

CHLORAL AND PICROTOXINE.

Husemann, in his investigations of the antagonisms of chloral, found that picrotoxine was to be included among the agents that act in opposition to it. The only reliable researches in regard to this antagonism are those of Dr. J. Crichton Browne, of the West Riding Lunatic Asylum, England. Picrotoxine, it may be stated, is the active principle of *Cocculus Indicus*, but it is not properly an alkaloid, and does not combine with acids to form salts. Its action on the brain is to produce delirium and stupor, and it gives rise to epileptiform, tonic, and clonic convulsions, which are succeeded by coma and insensibility. It has the power of suspending the reflex functions, as well as the irritability of both the motor and sensory nerves.

At first respiration and the pulse-rate are quickened by it for a brief period; but this preliminary excitement is quickly followed by a more permanent depressing effect, the respiration becoming shallow and the heart's action enfeebled. The temperature, also, which at first is slightly elevated, becomes reduced, especially after the convulsions. On comparing the physiological effects of the two agents, therefore, we find that they are antagonistic in their effects on the cerebrum and spinal cord, but not on the heart and respiration. Dr. Browne summarizes his conclusions from experiments on animals as follows:

"Chloral hydrate is physiologically antagonistic to picrotoxine in rabbits and guinea-pigs, and may save life when administered fifteen to twenty minutes after a fatal dose of the latter. There is no antagonisms exerted between these two agents on cats; death being caused by paralysis of the heart, a result in which both participate." An examination into the mechanism of the antagonism, which, from Dr. Browne's researches, it must be admitted is very limited, shows that it must be confined to the cerebrum and the reflex, motor, and sensory functions of the spinal cord, not extending to the cardiac and respiratory functions.

CHLORAL AND ATROPIA.

The antagonism between chloral and atropia was first studied by myself, and later by Husemann, Fothergill, and others. The physiological actions of both of these agents having already engaged our attention, we may proceed directly to an examination of their antagonistic action. On the brain and spinal cord they act in an opposed manner to a limited extent. Atropia diminishes the hypnotic effect of chloral, and the stupor and insensibility produced by it are counteracted by atropia in the same degree as by strychnia. On the spinal cord they act in a different manner, and, to a certain extent, antagonistically. The action of atropia on the spinal cord and veins is of a complex nature; having a tetanizing effect upon the cord, exalting its reflex function, and paralyzing the motor nerves, while it greatly diminishes the irritability of the sensory nerves. On the other hand, chloral suspends the reflex function of the cord and causes a paralysis which is purely spinal. Both the agents, however, produce motor-paralysis. On the circulation and respiration their action is decidedly and obviously antagonistic; a point which is abundantly confirmed both by clinical experience and experiments upon animals. In animals, however, owing to the fact that such drugs have a more concentrated and overwhelming effect on the brain, on account of their less complex cerebral development, only rarely does it occur that death can be averted by the employment of the antagonist after a lethal dose of either of them.

Whilst the good effects of atropia in preventing death from chloral by failure of the heart's action are very probable, it does not follow that the converse of this is true. Although there are no clinical or experimental data to depend upon in regard to this point, it must be granted that chloral could only act in the same manner as morphia under the circumstances, viz., by reducing the strain upon the cardiac and respiratory centres caused by the stimulating effect of the atropia. In cases of poisoning by chloral it is better to give a small dose of atropia and repeat it at short intervals until the characteristic effects of the drug are noticeable, rather than to administer a large dose at once. Unless caution is observed in this respect, the evils of atropia-poisoning may be added to chloral-narcosis. When there is a return of reflex irritability, an improvement in the pulse and respiration, and a dilatation of the pupil, all the good effects that can be obtained by the use of the antagonist have been secured, and it would only be foolish and dangerous to persist further in its employment.

THE ANTAGONISTS TO THE CARDIAC AND RESPIRATORY DEPRESSANTS.

We have now reached a most important and interesting point in the course. From a physiological, as well as a clinical point of view it is very desirable to know the various relations existing between those remedies which act upon the heart and the lungs. Let us first consider the action of .

OPIUM AND VERATRUM VIRIDE.

It has long been known that tincture of opium counteracts the depressing effect of veratrum viride upon the circulation, though I have been unable to find when or by whom this was discovered. The first instance of opium-poisoning treated by veratrum viride, so far as I am aware, is that reported by Dr. J. S. Todd, of Georgia. The patient took, with suicidal intent, a quantity of laudanum representing forty grains of crude opium. Emetics were administered, but they did not act until long after the whole amount had been absorbed. The other treatment consisted in the hypodermatic injection of tincture of veratrum viride and whiskey, and of atropia until the pupils became dilated. When so many agents were resorted to, it must have been difficult to decide which was of the most service in overcoming the opium narcosis; but Dr. Todd attributed the principal effect to the veratrum viride. Dr. Haldeman, of Zanesville, Ohio, also reports cases of opium-poisoning successfully treated with veratrum viride. No experimental researches have as yet been published in regard to the antagonism; but during the past summer and autumn I have been making a series of experiments upon animals (rabbits chiefly), at my laboratory at the Jefferson Medical College, for the purpose of testing it. In the first place I ascertained that the minimum lethal dose of fluid extract of veratrum viride (U. S. P.) was three minims per pound weight. To this quantity from three to five minims (according to the weight of the animal experimented upon) of Magendie's solution of morphia seems to be antagonistic. When the antagonist was used in the proper proportion, the nausea and vomiting, the muscular paresis, and the depression of the heart and respiration were all prevented, and the animal's life saved. When the effects of the morphia preponderated the pupils became contracted, convulsions were produced, drowsiness, deepening into coma, succeeded, and the effects of the veratrum viride disappeared. The same results were observed when frogs were employed instead of rabbits; and the antagonism would seem, therefore, to be clearly established. I found that the antagonism was exerted after ten, and even twenty minutes; but further experiment is necessary to determine whether this is the case at a longer interval. An interesting feature about the antagonism is that whether opium is used against veratrum viride, or *vice versa*, the opposed action is equally marked.

It is now incumbent on us to study the nature and mechanism of this antagonism. Veratrum viride has no effect on the mental functions, but causes cerebral anæmia; while opium causes excitement of the mental functions, followed by drowsiness, coma, and insensibility. Veratrum depresses the vaso-motor centres, and reduces the arterial tension and the temperature; while opium (if the dose is less than lethal, and especially in the form of morphia subcutaneously injected) stimulates the vaso-motor functions, increases the arterial tension, and maintains the temperature. On the heart-muscle, veratrum viride acts as a direct depressant, and on the respiratory muscles as a paralyzer; while opium in doses less than lethal has a marked effect in maintaining respiration and the action of the heart. Veratrum viride increases secretion generally, the saliva and sweat especially; while opium diminishes secretion, as a rule, though under some circumstances it increases perspiration. Veratrum is a paralyzer, acting upon the motor-spinal functions, but leaving the motor nerve-trunks and muscles intact; while opium, in less than lethal doses, opposes the action of veratrum viride in this respect. I cannot too strongly insist upon the difference in the action of opium when given in medicinal and in lethal doses, and in using it to counteract the effects of a poisonous dose of veratrum viride. It is much better to employ the former than to administer the remedy so freely that its effects will approximate those of the veratrum viride.

A sufficient number of cases have now been reported to fully establish the utility of employing one of these agents, if judiciously administered, to counteract the effects of a poisonous dose of the other.

OPIUM AND GELSEMIUM.

The action of gelsemium in general resembles that of veratrum viride, but in some particulars there are important differences between the two. Gelsemium is more distinctly a paralyzer, causing drooping of the upper eyelid, dilatation of the pupil, and diplopia, by paralyzing the third nerve. By its action on the brain it causes drowsiness and stupor, but does not interfere with the mental functions until its effects have resulted in carbonic acid narcosis. Gelsemium paralyzes the respiration, which ceases before the action of the heart. It is not, as generally supposed, an arterial sedative, since the depression of the circulation is merely secondary to its depressing effect on the respiration. The paralyzing action of gelsemium is spinal; neither the motor nerves nor the muscles being affected by it. It is obvious that opium in medicinal doses must be antagonistic to gelsemium, preventing the respiratory and cardiac depression, and averting death, unless the nervous centres be entirely overwhelmed by the amount of the poison. A striking instance of the antagonistic action of the two agents in man is afforded in a case related by Dr. George S. Courtright in the *Cincinnati Lancet and Observer*, in which life was saved by the subcutaneous injection of morphia after probably a tablespoonful of tincture of gelsemium had been taken.

On animals I have pursued the same line of observations as in the case of veratrum viride, and have found that the antagonism is admirably shown on the pupil, the respiration, and the action of the heart; although I have not been able to avert death on account of the severity of the cerebral effects of the two agents. In the same way morphia antagonizes the depressing effects of aconite; and the same facts which hold good in regard to the opposed actions of opium and veratrum viride, have been proved both experimentally and clinically to be true of those of opium and aconite.

MORPHIA AND COCAINE, THEINE, CAFFEINE AND GUARANINE.

One of the most interesting researches undertaken by the committee of the British Medical Association, of which Dr. Bennett was chairman, was that in regard to the supposed antagonism between morphia on the one hand and the alkaloids of coca, tea, coffee, and guarana on the other. It was found that the physiological action of these alkaloids was practically identical; their effects being "cerebral excitement, succeeded by coma, when the quantity is large; loss of sensibility, which is partial when the dose is small, and complete when the dose is large; tetanic spasms and convulsions; and paralysis of the posterior columns of the spinal cord and the peripheral sensory nerves, leaving the anterior columns and the motor nerves unaffected. At first they increase and finally they diminish the force and frequency of the cardiac contractions, and first irritate and then paralyze the vaso-motor nerves." It will be seen, therefore, that some of these actions are promoted, and others opposed by morphia. The researches of the committee demonstrate that there is some foundation for the popular idea that strong decoctions of tea and coffee are of service in opium-poisoning. Thus, they found that theine was antagonistic to miconate of morphia, and that the action of one so far modified that of the other as to avert death after a fatal dose of either.

MORPHIA AND CHLOROFORM.

As paralysis of the heart or of the respiration, or possibly by the simultaneous depression of both functions, is the mode of death from chloroform and other anæsthetics, it is certainly very desirable that we should have an agent which will antagonize and prevent this fatal tendency. In the subcutaneous injection of morphia I am entirely convinced that we do possess such an agent; and it is a matter of great surprise to me that surgeons have not more generally availed themselves of the indisputable advantages of mixed anæsthesia. It was about the same time that Claude Bernard and Nussbaum demonstrated the great utility of the method of inducing anæsthesia by the subcutaneous injection of morphia combined with the inhalation of chloroform—Bernard administering the morphia a few minutes before commencing the inhalation, and Nussbaum not until the latter was well under way. Morphia and chloroform act on the same cellular elements of the brain, and agree in the production of anæsthesia, but they are opposed in their action on other structures and organs—an opposition which renders their combined use safer. When morphia is injected before the inhalation of the anæsthetic is begun (which is the preferable method on account of the manner in which it facilitates the latter), the irritability of the bronchial mucous membrane is so far overcome as to permit the inhalation to proceed quietly; the stage of excitement is prevented, and consequently the danger from asphyxia which sometimes accompanies this; the nausea and vomiting are also obviated, and the anæsthetic effect is prolonged without the aid of further inhalation. In addition, the nausea and vomiting, after-pain and depression which follow the use of anæsthetics, as well as the dangerous syncope which sometimes results, can be prevented to a great extent by this method. If the morphia and the chloroform inhalation be carefully and properly combined, it is possible to produce anæsthesia without loss of consciousness, a point in regard to which Bossis says in his thesis on this subject: "There may be obtained in man, with a little attention, by the combined action of chloroform and morphia, a state of complete insensibility to pain, with preservation, to a partial extent, of the intelligence, tactile sensibility, auditory and visual, and of the voluntary movements. From the practical point of view, the analgesia obtained by the combined action differs completely from the demianæsthesia caused by the employment of chloroform or ether singly, in that it is not preceded or accompanied by a period of hyperæsthesia with violent excitement, and the tendency to exaggerated reflex arrests of the heart and after-syncope."

From the practical experience thus far accumulated there can be no doubt that morphia, used after the method of Bernard, greatly facilitates the induction of anæsthesia and materially diminishes its dangers. I have maintained that for this purpose atropia in combination with morphia should be preferred to morphia alone, on account of the greater stimulating effect thus produced upon the cardiac and respiratory centres. It might, perhaps, be supposed that atropia alone would be better than morphia; but it must not be forgotten that stimulation is inevitably followed by reaction, and morphia has a power of continued support which atropia does not possess. When administered together under the circumstances, the evil effects of both are antagonized, and the power of both to support the heart and respiration utilized. The quantity of morphia employed should rarely exceed one-fourth of a grain, and of atropia one-hundredth of a grain.

(Having spoken of the effect of strychnia as a stimulant of the respiratory function, the lecturer proceeded as follows:)

An opposition of actions has been determined to exist between

STRYCHNIA AND NITRITE OF AMYL.

These substances act antagonistically on the nervous system of animal life and on the sympathetic system. Nitrite of amyl suspends the reflex function of the spinal cord, and causes paralysis of the muscular system, death ensuing from paralysis of the respiratory muscles. Its most characteristic effects are those upon the heart and arterial system; the arterial tension being depressed to the lowest point, while the action of the heart is necessarily very greatly increased on account of the enormous dilatation of the peripheral vessels produced. These effects being the opposite of those caused by strychnia, an antagonism may be presumed from a physiological standpoint, and the experimental researches of Dr. Gray, of Glasgow, strongly support this view.

(The hour having now expired, Dr. Bartholow was obliged to omit a portion of the lecture, and concluded in the following words:)

With the antagonisms discussed in this lecture rather hastily, as the subject matter of the course will permit no fuller treatment, I close this part of the subject, or the antagonism between medicines. I have yet to discuss, in the remaining lectures, that large and important practical subject—the antagonism between remedies and diseases.

In my next lecture, I will, therefore, begin the consideration of this topic, which will not only enforce the lessons derived from the study of the physiological antagonisms between medicines, but will, I hope, demonstrate a path which we may surely follow in the treatment of many diseases.

Eighty-three Grains of Opium vs. One quarter of a Grain of Atropia.—Dr. J. W. Bryant reports, in the *Virginia Medical Monthly*, a case of opium-poisoning successfully treated with gr. ¼ of atropia. The patient, a man, had taken ℥ iiss. of laudanum on an empty stomach. Two hours passed before anything was done for his relief. Emesis could not be produced, and as there was no stomach-pump, Dr. Bryant had to rely entirely on atropia. One-fourth of a grain was given hypodermically in four hours in six doses. When it was given the man had marked symptoms of opium narcosis: lightly contracted pupil, slow and labored respiration, slow and weak pulse. The first perceptible effect of the atropia was after the second dose, when the pupil began to dilate slowly; it was not fully dilated until after the sixth dose. The pulse continued to rise until from 55 it was 125. There was no effect upon the respiratory centres. The galvanic battery was used for a time with no very striking result. At one A.M. the patient was left, the physicians not knowing whether he would live or die. Next morning he was awake and conscious, but in the condition of a man who had been on a "big spree." Some delirium appeared the next day, but the patient was soon in good condition again. His bowels were not constipated.

Original Communications.

AMBLYOPIA FROM THE ABUSE OF TOBACCO AND ALCOHOL.

By DAVID WEBSTER, M.D.,

NEW YORK.

(Read before the Medical Society of the County of New York, November 29, 1880.)

Mr. President and Gentlemen—In coming before you this evening with some remarks upon the amblyopia or impairment of vision, which arises from the abuse of alcohol and tobacco, I believe I have selected a subject which will prove to be of interest to the general practitioner as well as to the specialist. Probably every physician has to deal with the poisonous effects upon the nervous system of alcohol and tobacco in one form or another. And, I think, the careful medical man, when called to a case of chronic disease in the adult male, and even in some cases of acute trouble, rarely omits to inquire into his habits as regards the use of tobacco and spirits, and often finds it necessary to regulate, or to forbid entirely the use of these drugs.

That the abuse of alcohol alone, or of alcohol and tobacco combined, may produce impairment of vision, ranging all the way from the slightest blurring to total blindness, no physician acquainted with the subject will, I think, venture to deny.

Some, however, doubt that *tobacco alone* ever causes impairment of vision. And indeed it is difficult to demonstrate, beyond all controversy, that it ever does. Such cases seem to occur very infrequently in this country, and when we meet with one of them we often find it very difficult to exclude all other causes of amblyopia. Take, for instance, the case of J. A. (No. XII. of the cases herewith presented). He was sixty years of age, and had smoked a strong pipe most of the time when awake, for over forty years. He had rarely tasted liquor. He had never had syphilis nor malarial disease. In short, no other probable cause could be found for his impairment of vision than his being perpetually subjected to the poisonous influences of his pipe. On the other hand, how often do we meet with cases of amblyopia for which we can find *no* probable cause! May this case not have really belonged to that category, and the excessive use of tobacco merely a coincidence? We think the sequel goes to prove that it was really a case of tobacco amblyopia. The patient's tobacco was cut off, and, at the end of a week, without any treatment or medication, his sight had doubled itself in one eye and *nearly* doubled itself in the other.

Dr. Edward T. Ely, of this city, recently examined the eyes and tested the vision of 102 workers in tobacco, chiefly cigar-makers. The doctor sums up his results in the following words: "My own impressions, gathered from these examinations as well as from other experience, are, that tobacco has of tself only a comparatively slight influence in impairing the vision; that working in tobacco is as healthful as most other sedentary occupations; that n certain persons peculiarly susceptible to it, or, when combined with other noxious influences, it may mpair the vision or the general health, just as has been claimed for it; and that constant contact with t, as with other poisons, may beget a tolerance of it ufficient to contradict all theory." The doctor also says, and, I think, correctly: "A tobacco amblyopia is mentioned in all modern text-books on the eye, and most ophthalmologists believe in it, and on good and sufficient evidence, so far as we can judge."

Mr. Jonathan Hutchinson, of London, seems to have no doubt of the effect of tobacco in producing amblyopia. In the Ophthalmic Hospital reports, vol. vii., he publishes twenty-nine cases that have come under his care. Of these cases he says: "For myself, I may briefly avow that I have scrupulously investigated other possible causes, and that I feel no hesitation in believing that in most of these cases tobacco is the real one." In two of Mr. Hutchinson's cases there was white atrophy of both optic disks with total blindness. In one case the disks were very white and the patient had only perception of light. The other cases had vision ranging from perception of light to two-thirds the normal. Mr. H. states in this article that he has long held the opinion "that when tobacco causes blindness it does so in virtue of an idiosyncrasy," and that "it is by no means improbable that such idiosyncrasy will be found occasionally in several members of the same family."

As regards such family idiosyncrasies, I have seen several instances of optic nerve atrophy occurring in adult males who were brothers, but, in these cases, the disease could not be attributed to the use of tobacco, nor could any very probable cause be assigned.

In vol. viii. (*ibid.*) Mr. H. publishes tables containing the "facts as to progress" in sixty-four cases of tobacco amaurosis. "Recovery or great improvement took place in seventy-five *per cent.* In four cases the disease was arrested, sight remaining stationary after a certain degree of failure. In seven cases sight became worse while under care, and five others were quite blind when first seen, and are believed to have continued so."

The fact that so careful and so competent an observer as Mr. Hutchinson has made a diagnosis of tobacco amaurosis in so large a number of cases is, of itself, one of the strongest of arguments in favor of the existence of such a disease. At the same time, it would appear that it is met with much more frequently in England than in any other country. This, according to Mr. Hutchinson, seems to be accounted for by the fact that the poorer classes of Englishmen usually smoke a kind of tobacco called *shag*, one of the strongest and worst of its forms.

As regards the ophthalmoscopic appearances found in amblyopia from alcohol and tobacco, I think all ophthalmologists will agree that "there is no special lesion of the fundus of the eye that would at once enable one to diagnosticate the nature of the disease as depending upon the excessive use of alcohol or tobacco."

Before making a diagnosis of amblyopia from tobacco and alcohol, we must get in all the facts which go to make up the case—the clinical history, the symptoms, subjective and objective, the various complications, the habits of the patient, as well as the ophthalmoscopic appearances.

I must confess, however, that when a man comes to me on account of failing vision, and I find the characteristic "chloroform odor" on his breath, and the scent of tobacco issuing from every pore of his skin—a condition which is quickly appreciated while making an ophthalmoscopic examination by the direct method—I at once suspect that I have discovered the cause of his affection, and am only likely to have my opinion changed by *positive evidence*, ophthalmoscopically, or otherwise. For instance, if I found such a patient had choroidal atrophy, or choked disk, or incipient cataract. I would hardly refer these to alcohol and tobacco as a cause.

The ophthalmoscopic appearances in this disease are, however, within a certain range, quite constant, and are always referable to the optic nerve and retina. When seen in its earlier stages, there are the appearances of a low grade of neuritis, or, at least, of hyperæmia of the optic disk. Later on, there are appearances of incipient optic-nerve atrophy.

In the cases herewith presented, the ophthalmoscopic lesion most frequently noted was "incipient atrophy of optic nerves." This was noted in seven cases out of the twenty. In two cases, "optic disks too pale;" in two cases, "optic disks of a dirty, brick-dust color;" in two cases, "nasal half of disk too red and temporal half too white;" in one case, "disks too pale, and white bands by the sides of some of the retinal vessels," showing the existence of a perivasculitis.

In some cases, not well enough recorded to be included in this paper, we find it noted: "Fundus has a smirched, dirty look, but no lesion," or, "smirched condition of optic disks; surface of disks red and outline seen with difficulty, yet an abnormal whiteness shining through from beneath the surface; venous pulsation." Of course, it is only possible for those skilled in the use of the ophthalmoscope to appreciate these nice distinctions in the ophthalmoscopic appearances, but the physician will readily understand us when we say that they all refer to different degrees of vascularity, of inflammation or atrophy of the optic nerve and retina.

In eighteen of the cases herewith presented, both alcohol and tobacco were used in excess; in one case tobacco was used excessively, from ten to fifteen strong cigars daily for ten years, and alcohol moderately, only an occasional glass of gin being taken; and in one case, as before stated, the amblyopia seemed to be wholly due to the abuse of tobacco. In this case the vision rose from $\frac{5}{200}$ to $_{70}$ in each eye, the patient abstaining from tobacco, and being subjected to appropriate treatment.

In some of these cases we omitted to note the length of time during which the patient had been addicted to the habitual use of spirits and tobacco; but in most of the cases it was many years—in one case ten, in one case thirty-eight, and in one case forty years.

The time that had transpired since the patient first noticed impairment of vision varied from three weeks to over a year.

In nearly all the cases the impairment of sight had been *gradual*, although in one case it had been ushered in *suddenly* "after prolonged exposure of the eyes to glare on the water." In this case, however, the sight continued to deteriorate gradually after the first onset of the disease. In all the cases there was simultaneous decay of vision in both eyes. In nine cases, or in nearly *fifty per cent.*, the amount of impairment was exactly the same in both eyes. The greatest difference of vision in the two eyes of any one patient was where one eye had vision $\frac{20}{30}$ and the other $\frac{20}{100}$.

In several cases it may be doubted whether the impairment of vision was *wholly* due to alcohol- and tobacco-poisoning. Several of the patients had been subjects of malaria; one said that his sight began to fail during an attack of "bilious diarrhœa;" one had had syphilis, but there was no evidence of any syphilitic disease of his eyes, and on the other hand he was habitually saturated with spirits and tobacco, and recovered his vision when these were cut off, and he had been under treatment for a few weeks.

The patients were all men, their ages ranging from thirty to sixty. Two were physicians, two were gentlemen of leisure, one a sea-captain, one a lawyer, one a merchant, one clerk, one speculator, one auctioneer, one machinist, one equestrian, one mechanic, one watchman, one coachman, and one laborer.

About one-half the number were married and the other half bachelors.

In all of these cases, or nearly all, the treatment by hypodermic injections of strychnia was pursued, and generally with great apparent benefit. Our routine method of using the strychnia is this: We have put up, at a reliable apothecary's, four grains of nitrate of strychnia in an ounce of distilled water. Each minim of this solution contains one one-hundred-and-twentieth of a grain of nitrate of strychnia. We usually begin by injecting into the subcutaneous cellular tissue three minims of this solution, or one-fortieth of a grain of the drug. We then increase the amount injected by one minim daily, giving one injection a day until some of the physiological effects of the drug have been produced.

The most frequent of these we have found to be a kind of stiffening of the legs with a tendency to "kick out" in an irregular manner. We have usually kept the patient sitting for fifteen or twenty minutes after the injection, in order to observe the effect. Frequently the first symptom of any effect upon the system would be this uncontrollable tendency to step higher, or to one side, or in some direction not in accordance with the wishes of the patient while going down-stairs to go out. At the same time stiffness of the muscles of the thighs would be complained of, and sometimes slight spasmodic twitchings, or rigidity, of the muscles of the jaws or other muscles would be observed. The next most frequent symptom was vertigo, and sometimes headache. I remember that one man, who lived in Williamsburg, was attacked with a sudden dizziness, and fell down on the sidewalk when he had nearly reached his home. He soon recovered his self-control, however, and reached home without assistance. In a very few cases "little knotty pains" in the bowels were complained of, just such pains as I have heard some persons say they experienced from drinking lager beer.

I may say, however, that although we have been using nitrate of strychnia hypodermically for over eight years, and often in three or four different patients a day, we have never yet seen any alarming symptoms from its use, and we do not think there is much danger attendant upon its use in the way we have described. Cases have been reported, however, in which symptoms of decided strychnine-poisoning followed its use in amaurosis and amblyopia. But I have not heard of any *fatal* results.

One very disagreeable complication, however, arose in several cases, and that was a tendency to inflammation at the site of the puncture.

In one case a small abscess formed and persisted for several weeks in spite of such treatment as was employed. When this complication occurs a change in the treatment usually seems to be indicated.

We have commonly given our injections in the back of the neck, sometimes in the arm, and less frequently in the temple.

The question naturally arises, How long should we continue these hypodermic injections of strychnia? Our practice has been to continue them up to physiological effects, and then to stop them if no marked benefit has ensued. If the vision continues to improve after physiological effects have been reached, the injections may be continued for an indefinite period, that is, as long as they seem to be doing any good. The quantity injected should be diminished, however, so as just to fall short of physiological effects.

We have, in some cases, after reaching physiological effects, stopped the strychnia injections for a few weeks, and then resumed them again, going over the same ground as at first with decided benefit.

The largest dose of strychnia I have injected in any one case was, to the best of my recollection, one-fifth of a grain. I have seen one patient, however, who, under the care of a friend of mine, had the dose increased to one-half of a grain before physiological effects were produced. Usually physiological effects show themselves after you have increased the dose to from one-fifteenth to one-tenth of a grain.

You must not suppose, gentlemen, that in these cases of amblyopia from alcohol- and tobacco-poisoning we do nothing for the patient but treat him with hypodermic injections of strychnine. The first and most important thing of all in the treatment is *entire abstinence* from the poisons which caused the disease. We find it the best way to cut off the alcohol and tobacco *at once and completely*. The "tapering-off system" will not do here. If the patient be allowed to use either tobacco or alcohol at all, he will be almost sure to do so to the point of saturation or toxic effect. It is certainly much easier for a person accustomed to the immoderate use of tobacco and alcohol to drop them entirely than to limit their use short of satiety. And generally they are ready and willing to do so when the importance of such abstinence is fairly represented to them, and they are told to choose between the continuation of the indulgence and their eyesight. Such patients have frequently told me that they were themselves surprised at the facility with which they dropped the habit, their "hankering" having continued, to any unpleasant degree, for only a few days. I have known some of these patients to *relapse* into their habits of drinking and smoking, but strange to say, I do not recollect any patient who came to us for treatment a second time, having been once cured. Perhaps the amblyopia does not recur; perhaps such patients are ashamed to apply a second time to the same physician for treatment, being conscious of a sense of moral degradation in having neglected to follow his advice.

Besides stopping the use of tobacco and alcohol, and placing the patient upon injections of nitrate of strychnia, his hygienic circumstances should be carefully looked into, and his whole manner of living should be properly regulated. Of course other medicines besides strychnia are frequently indicated, and should be used.

Dr. Charles S. Bull, who published a paper in the *American Journal of Medical Sciences* for April, 1873, "On the Treatment of Various Forms of Amblyopia and Amaurosis," in which he reports twelve cases which he had treated with hypodermic injections of strychnine, gives the following as his conclusions in regard to the value of the strychnine treatment: "In all cases of functional amblyopia we may expect good and permanent results from strychnia; and even in some cases of organic origin, provided there be no extensive atrophy of the nerve-structures, some improvement is gained by the use of the drug."

Some of our colleagues say that they have no confidence whatever in the strychnine treatment, and do not resort to it at all, or, having tried it, and failed to get such good results as others have claimed, have abandoned it altogether.

Yet it seems to me that we may be reasonably sure that our patients of the class spoken of in this paper usually recover their vision more rapidly under the strychnine treatment than they would under any other. Look at Case V. of this series, for instance. On his first visit he had vision $\frac{14}{100}$ in each eye; one thirty-sixth of a grain of strychnia was injected, but reeking as he was with alcohol and tobacco, there was no immediate improvement. On his second visit, one week later, he, having abstained from tobacco and alcohol, had vision $\frac{20}{100}$ in right, and $\frac{20}{80}$ in left eye. A hypodermic of strych. nitrat. gr. $\frac{1}{30}$ was then given, and vision rose in *one minute* to $\frac{20}{60}$. *Five* minutes later, vision was $\frac{20}{40}$, the vision thus having *doubled* itself in one eye and *more than doubled* itself in the other within six minutes from the time of the injection.

Also look at the case of Mr. McK—— (Case VII.). He came to us with vision $\frac{5}{100}$ in each eye. We gave him a hypodermic of strych. nitrat. gr. $\frac{1}{24}$, and a few minutes later his vision rose to $\frac{20}{80}$ each eye, the sight being more than quadrupled in each eye before leaving his seat.

These cases would seem to demonstrate beyond a doubt that strychnia, used hypodermically, has a certain specific influence upon the visual apparatus. Dr. Bull, in the paper above cited, says, concerning the influence of strychnia upon the sense of sight, "the only point that we are sure of is that it produces a distinct irritation or excitement of the nervous portion of the visual apparatus."

There can be no doubt that most patients who are the victims of alcohol- and tobacco-poisoning would recover a certain amount of vision by simple abstinence from tobacco and spirits. Cases IX., X., XII., and XVI. bear out this assertion. Each of these patients abstained for one week without treatment. The vision of Case IX. went up from $\frac{20}{200}$ to $\frac{20}{70}$ each eye; the vision of Case X. rose from $\frac{15}{200}$ to $\frac{20}{100}$ each eye; the vision of Case XII. rose from $\frac{5}{200}$ each eye to $\frac{5}{100}$ right, and $\frac{5}{126}$ left; and the vision of Case XVI. rose in right eye from $\frac{20}{100}$ to $\frac{20}{80}$, and in left eye from $\frac{20}{80}$ to $\frac{20}{60}$.

Of the twenty cases here reported the vision was improved, while under treatment, in all the cases except *two*, in which it remained unchanged. In seven cases, or in about thirty-four per cent., the vision rose from various degrees of impairment to the normal standard, in one case going up from counting fingers at twelve and fifteen feet to $\frac{20}{20}$ each eye.

If I were to formulate my conclusions drawn from these cases and from other sources of information, they would be about as follows:

1. Amblyopia from poisoning by alcohol alone, or by alcohol and tobacco combined, is not uncommon.
2. Amblyopia from poisoning by tobacco alone *does occur*, but, in this country, somewhat rarely.
3. Cases of amblyopia from abuse of tobacco and alcohol will usually improve, perhaps to a limited extent, on simple abstinence from the poisons causing the disease.
4. They will improve much more rapidly under treatment by hypodermic injections of strychnia, this drug having a specific stimulating influence upon the nervous portion of the visual apparatus.

My thanks are due to Dr. C. R. Agnew for his permission to make use of the cases drawn from his case-books.

CASE I.—Dr. G——, aged thirty-two years; American, married; came under observation in January, 1873. His vision had been acute until the previous June, when it began to grow dim, without pain or other symptom, "just as a twilight sets in." The failure of sight gradually increased until now. Right eye, V. = fingers at fifteen feet, and left eye, V. = fingers at twelve feet. He chews and smokes tobacco freely, and takes two or three drinks of whiskey daily, occasionally more.

Ophthalmoscopic examination, through dilated pupils, reveals "a dirty-looking macular region and whitish optic disk" in both eyes.

January 28th.—The patient was put upon hypodermic injections of nitrate of strychnia, commencing with gr. $\frac{1}{4}$, and increasing to gr. $\frac{1}{24}$. The strychnia was then stopped for a few days, and the patient put upon iodide of potassium and bromide of ammonium.

February 10th.—Urine examined by Dr. Edward Curtis, and pronounced normal.

February 12th.—Patient examined by Dr. E. C. Seguin, who finds no evidence of intracranial or spinal disease.

The strychnine injections were then renewed, and carried from gr. $\frac{1}{24}$ up to gr. $\frac{1}{10}$, when the patient returned to his home, with only slight improvement of vision.

June 11, 1875.—Vision $\frac{20}{20}$ in each eye. Used no medicine but cod-liver oil after leaving New York, and took that only two months. He attributes his recovery of vision more to total abstinence from whiskey and tobacco than to any medication. His recovery was very slow, and he could see sufficiently well to shoot last fall for the first.

October 4, 1878.—He has had no further trouble with his eyes. Vision remains $\frac{20}{20}$.

Case II.—A. C. R——, aged fifty-four years; American, bachelor; officer in U. S. Navy; came under observation June 16, 1875. First noticed sight was beginning to fail about two months ago, while in Savannah, during an attack of "bilious diarrhœa," which "laid him up" for three weeks. Had chills and fever when a boy. Has never been subject to headache; never had venereal disease. No albumen in urine.

Has used tobacco since sixteen years of age, and has smoked excessively this winter. Has used wine and spirits habitually all his life, never to excess; "only five or six glasses of whiskey a day."

The patient is very thin. He says he never had much flesh, but lost much of what he had during his illness in Savannah.

R. V., $\frac{20}{70}$; L. V., $\frac{20}{40}$. No improvement with glasses.

Ophthalmoscopic examination: "Apparently has incipient atrophy of both optic nerves." Advised to stop the use of tobacco and spirits, and injected strychniæ nitrat., gr. $\frac{1}{24}$.

June 17th.—Injected strych. gr. $\frac{1}{20}$.

June 22d.—Has smoked only three cigars daily, and has drank no spirits. Vision remains the same. Injected strych., gr. $\frac{1}{17}$.

July 6th.—R. V., $\frac{20}{40}$; L. V., $\frac{20}{20}$. Has had a daily injection of strych. nitrat., the dose to-day being gr. $\frac{1}{8}$.

July 15th.—Vision remains the same as when last tested. Injected to-day strych. nitrat., gr. $\frac{1}{8}$, which produced some "stiffening of his legs." Sent into the country.

September 2d.—Has been at Richfield, N. Y., for three weeks, during which he gained 3¾ lbs. in weight. While at Richfield he drank three large glasses of mixed milk and cream daily. He went thence to Saratoga, where he stayed three weeks, but gained no flesh while there. Vision, $\frac{20}{20}$ each eye; visual fields normal.

April 20, 1879.—Captain R. states that he has had no further trouble with his eyes.

Case III.—Thos. McS——, aged thirty-one years; Irish, married; coachman; came under observation January 8, 1874. A year ago had some redness of his eyes during the snowy weather. Never had pain in his eyes or head; never had syphilis nor malarial disease. Noticed sight getting bad for the last five weeks.

Smokes a pipe most of the time when not driving, and drinks freely of ale, and occasionally of whiskey.

Vision $\frac{15}{200}$ each eye; no improvement with glasses.

Ophthalmoscopic examination: Dirty, congested look of fundus and nasal half of disk; temporal half of disk too white. Injected strych. nit., gr. $\frac{1}{24}$. No immediate improvement of vision.

January 15th.—Has abstained from tobacco and spirits for a week, and vision remains the same. Injected strych. nit., gr. $\frac{1}{24}$, and before he left his seat vision rose to $\frac{20}{200}$ in each eye.

Mr. McS—— was then sent to the Manhattan Eye and Ear Hospital, and placed upon daily increasing injections of nitrate of strychnia. These injections were continued for some days after the physiological effects of the drug had been reached. The patient states that his sight became much better while under treatment, but no note was made of the amount of improvement.

February 10, 1879.—Vision $\frac{20}{20}$ each eye. The patient states that he smokes and drinks only occasionally.

Case IV.—Doctor F——, aged fifty-four years; married, Irish; has noticed that his sight was failing for several months. Now, September 4, 1876, R. V., $\frac{20}{100}$; L. V., $\frac{20}{70}$. No improvement with glasses. He has for many years been addicted to an excessive use of tobacco and spirits.

Ophthalmoscopic examination: "Incipient atrophy of both optic nerves." Advised to quit the use tobacco and spirits, and to place himself upon the use of nitrate of strychnia.

February 24, 1879.—Dr. F——, states that immediately after consulting me, his son, also a physician, began to inject him with nitrate of strychnia, commencing with a small dose and increasing a little daily, until physiological effects were produced. He then began taking it in increasing doses by the stomach. He increased the dose up to gr. $\frac{1}{8}$ daily, and this having affected his muscular system slightly, he stopped the drug. He has been taking it from time to time ever since, and has abstained from the use of tobacco and alcohol. His vision gradually improved from the first. Now, V. $\frac{20}{20}$ each eye; visual fields normal.

Case V.—G. B. W——, aged thirty-seven years; married, clerk; came under observation October 23, 1873. Blurring of sight came on suddenly after prolonged exposure to glare on the water three or four months ago, and has since gradually increased. For several years has smoked on an average fifteen strong cigars daily, and has drank on an average eight or ten glasses of brandy a day. Had what his physician called a chancre fifteen years ago, but it was never followed by any of the constitutional symptoms of syphilis.

Vision $\frac{14}{100}$ each eye; no improvement with glasses. No color scotoma, nor limitation of visual fields.

Ophthalmoscopic examination: "A dirty, ill-defined appearance of the optic nerve and retina." Injected strych. nit., gr. $\frac{1}{36}$. No immediate improvement of vision.

October 30th.—Has abstained from tobacco and alcohol for one week without treatment. R. V., $\frac{20}{100}$; L. V., $\frac{20}{80}$. Injected strych., gr. $\frac{1}{30}$, and one minute later V. $\frac{20}{50}$ both eyes. Five minutes later V. $\frac{20}{40}$ both eyes.

November 6th.—The injection has been daily increased, and the dose has reached gr. $\frac{1}{14}$. Vision $\frac{20}{30}$ both eyes.

November 7th.—Injected strych., gr. $\frac{1}{12}$, which produced such decided effects that the patient had to lie down for an hour before he had sufficient control of his limbs to leave the office.

November 17th.—Has had strych., gr. $\frac{1}{24}$, injected daily since last note. Vision $\frac{20}{20}$ each eye.

Case VI.—A. L——, aged fifty-eight years; American, married; speculator; said that his sight had been failing for the last nine months. He had for many years smoked, chewed, and drank to excess.

Ophthalmoscopic examination: "Disks dirty, atrophic excavation, retinal veins enlarged and pulsating."

R. V., $\frac{20}{80}$; L. V., $\frac{20}{100}$; no improvement with glasses. Placed upon daily injections of nitrate of strychnia. After three injections, gr. $\frac{1}{24}$, gr. $\frac{1}{20}$, and gr. $\frac{1}{18}$, vision rose to $\frac{20}{50}$ both eyes. After five more injections, R. V., $\frac{20}{40}$; L. V., $\frac{20}{50}$; and after three more, R. V., $\frac{20}{30}$; L. V., $\frac{20}{50}$. This patient was under treatment fourteen days, and received eleven injections, six of which were of gr. $\frac{1}{12}$ each. No physiological effects were produced.

Case VII.—Colin McK——, aged forty-nine years; machinist and engineer; could see well with spectacles up to three months ago, since which vision has gradually but rapidly failed. Has smoked from ten to fifteen strong cigars daily for ten years; occasionally drinks a glass or two of gin; drinks coffee four times a day. Vision, $\frac{6}{100}$ each eye; improved by $+\frac{1}{18}$, but not to $\frac{20}{200}$.

Ophthalmoscopic examination: "Incipient atrophy of optic nerves."

Strych. nitrat. gr. $\frac{1}{24}$ was injected into the back of the neck, and within five minutes vision rose to $\frac{20}{80}$ each eye.

He returned to his family physician with a letter, and we have not heard from him since.

Case VIII.—C. S. P——, aged forty-six years; auctioneer; saw well with glasses up to five weeks ago; read the newspapers up to nineteen days ago. Never had syphilis nor malaria. General health good.

Previous to the commencement of his failure of sight he was constantly under the influence of alcohol and tobacco, and still has his pipe in his mouth at least half the time.

Ophthalmoscopic examination: "Incipient atrophy of optic nerves." R. V., $\frac{20}{100}$; no improvement with glasses. L. V., $\frac{20}{30}$, with $+\frac{1}{48}$. Central scotoma of both eyes, but no color-blindness.

This patient was treated with strychnia injections from April 17th to May 10th, when he was discharged with vision unchanged, and has not been heard from since.

Case IX.—R. E——, aged forty-six years; complains of gradual impairment of sight. Drinks and smokes excessively. V. $\frac{20}{200}$ each; no improvement with glasses.

Ophthalmoscopic examination: "Optic disks of a dirty, brick-dust color."

Advised to abstain from tobacco and spirits and return in a week.

March 2d.—V. $\frac{20}{70}$ each eye, after a week's abstinence.

March 13th.—He has had five injections of strych. nitrat., the last being gr. $\frac{1}{15}$. V. $\frac{20}{50}$ each eye.

March 19th.—R. V., $\frac{20}{50}$; L. V., $\frac{20}{40}$.

Case X.—G. B——, aged fifty years; has long been addicted to the excessive use of tobacco and alcohol. Vision has been declining for several months, and is now $\frac{15}{200}$ each eye.

Ophthalmoscopic examination: "Incipient atrophy of optic nerves."

January 15th.—Has abstained from alcohol and tobacco one week without treatment. V. $\frac{20}{100}$ each eye.

January 25th.—Has had eight injections of strych. nitrat., the last dose being gr. $\frac{1}{12}$. R. V., $\frac{20}{50}$; L. V., $\frac{20}{30}$.

Case XI.—E. L——, aged fifty-five years; lawyer; came under observation June 16, 1875. Has smoked four or five cigars a day, and drank brandy and water in the evening for many years. Has had increasing mistiness of vision for three or four weeks. Puffiness of lower lids for years. Urine normal. Never had syphilis nor malaria. Never has headache nor pain in the eyes. Latterly he has "lost stomach." R. V., $\frac{20}{40}$; L. V., $\frac{20}{30}$; picking out the letters slowly. Reads J. 4 with glasses with difficulty.

Ophthalmoscopic examination: "Dirty disks."

June 22d.—Has smoked only one cigar a day, and drank no spirits, and has drank milk freely. Vision unchanged.

July 6th.—The dose of strych. nitrat. has been increased from gr. $\frac{1}{40}$ to gr. $\frac{1}{8}$. R. V., $\frac{20}{40}$; L. V., $\frac{20}{20}$.

July 15th.—The dose has been increased to gr. $\frac{1}{5}$. Slight physiological effects on arms and legs.

August 23d.—R. V., $\frac{20}{30}$; L. V., $\frac{20}{20}$. Can now see the lineaments of faces across the street, while before he could see only the dark outline. He had twenty-two injections in all.

Case XII.—J. A——, aged sixty years; Scotchman, married; mechanic; came under observation January 17, 1878. Has had failing eyesight for over a year. Has smoked a strong pipe most of his waking hours for more than forty years. Has rarely tasted liquor. No headache. Never had syphilis nor malaria. Urine normal. V. $\frac{5}{200}$ each eye.

Ophthalmoscopic examination: "Brick-dust atrophy of both optic nerves." Ordered to stop tobacco and return in a week.

January 24th.—R. V., $\frac{5}{100}$; L. V., $\frac{5}{120}$. Put upon strych. sulph. gr. $\frac{1}{60}$ thrice daily, by the mouth.

April 4th.—V. $\frac{20}{100}$ each eye. Put upon a mixture containing bromide of ammonium, iodide of potassium, sesquicarbonate of ammonia, and tincture of columbo.

July 23d.—V. $\frac{20}{70}$ each eye.

Case XIII.—M. C——, aged forty-eight years; laborer, married; came under observation January 2, 1879. Patient is partly deaf, and belongs to a family nearly all of whom are hard of hearing. Had malaria when fourteen years old. Never had venereal disease. Five months ago went to Coney Island, where he thinks the glare of the sun on the water injured his eyes, for the sight has since gradually failed.

Chews tobacco all the time. Smoked and drank excessively up to two weeks ago, when his physician ordered him to stop it.

R. V., $\frac{10}{200}$; L. V., $\frac{2}{200}$.; no improvement with glasses.

Ophthalmoscopic examination: "Incipient atrophy of optic nerves."

January 8th.—The dose of hypodermic strychnine has been carried up to gr. $\frac{1}{11}$.

R. V., $\frac{20}{200}$; L. V., $\frac{6}{200}$.

Case XIV.—T. W——, aged forty-one years; came under observation January 17, 1878. Stomach out of order. Is very nervous. Drinks, smokes, and chews freely. For years smoked ten or twelve cigar a day. Now averages five or six. Urine normal.

R. V., [illegible], with $+\frac{1}{24}$; L. V., $\frac{20}{80}$, with $+\frac{1}{30}$ c. ax. 90° ⌒ $-\frac{1}{60}$ c. ax. 180°.

Ophthalmoscopic examination: "Disks too pale; white bands by the sides of some of the retinal vessels."

January 30th.—The strychnia injections have been carried up to gr. $\frac{1}{4}$, which produces some stiffness of the thighs. R. V., $\frac{20}{70}$, Hm. $\frac{1}{16}$.; L. V., $\frac{20}{60}$, with + [illegible] c. ax. 90° ⌒ $-\frac{1}{30}$ c. ax. 180°.

Case XV.—J. M——, aged forty-two years; equestrian; married; came under observation September 24, 1877. Blurring of eyesight has been going on for over three months. Contracted "dumb ague" in Georgia some years ago.

Smokes seven or eight cigars daily, and drinks a great deal of whiskey.

Vision $\frac{20}{70}$ in each eye, and no improvement with glasses.

Ophthalmoscopic examination: "Incipient atrophy of optic nerves."

Ordered to quit tobacco and whiskey, and put upon dialyzed iron, with strych. sulph., gr. $\frac{1}{60}$, *ter in die.*

September 28th.—V. $\frac{20}{40}$ each. Appetite much improved.

October 8th.—Has had nine hypodermic injections of strych. nitrat., commencing with gr. $\frac{1}{40}$ and increasing to gr. $\frac{1}{14}$. V. $\frac{20}{30}$ each.

October 9th.—Injected strych., gr. $\frac{1}{10}$. Patient soon after became dizzy, and vision rose to $\frac{20}{20}$ each eye.

Case XVI.—G. M——, aged fifty-one years; married; merchant; came under observation July 10, 1876. At the age of seventeen he had scarlatina severely, which impaired his memory for a year. He had "camp fever" during the war, and chills and fever nine years ago. Never had syphilis.

Has for many years smoked three or four cigars a day, and has always drank more or less brandy or wine daily, but "never to excess."

Has had gradual impairment of vision for nine months, as though a vail were drawn over objects. Has for some time been under the care of a physician for his eyes, and has been taking the bromides without appreciable benefit.

R. V. $\frac{20}{100}$; no improvement with glasses; L. V. $\frac{20}{80}$, with $+\frac{1}{72}$.

Ophthalmoscopic examination: "A low grade of optic neuritis, with commencing atrophy of both optic nerves."

Advised to stop tobacco and spirits for a week and take no medicine.

July 17th.—Has practised abstinence for a week, as directed. R. V., $\frac{20}{80}$; L. V., $\frac{20}{60}$. Injected strych. nitrat., gr. $\frac{1}{24}$.

July 24th.—The dose of strych. nitrat. has been gradually increased to gr. $\frac{1}{10}$. Has had pain in forehead for three or four days. Vision $\frac{20}{50}$ each eye.

July 27th.—Strych. nitrat., gr. $\frac{1}{9}$, produces "leg symptoms."

August 11th.—Vision $\frac{20}{40}$ each eye.

August 22d.—Vision $\frac{20}{30}$ each eye. Is taking a daily injection of strych. nitrat., gr. $\frac{1}{5}$.

September 25th.—Vision $\frac{20}{20}$ each eye, with $+\frac{1}{72}$.

Case XVII.—J. M——, aged thirty-eight years; watchman; bachelor; came under observation March 28, 1879.

In the beginning of the winter got a pair of shoes that were a size too small for him, and he thinks wearing them affected his eyes. Three or four weeks after he commenced to wear them he first noticed, while reading a newspaper, that his sight was failing, and it has gradually grown worse ever since.

He has smoked both pipe and cigars since he was fifteen years old. Smokes at least half a paper of tobacco daily, and drinks a glass of ale every day, and often whiskey. Had chills and fever five years ago. Not subject to headache. Never had venereal disease, but has been addicted to masturbation since the age of seventeen.

Urine and heart examined by experts, and found to be normal.

Vision $\frac{40}{70}$ each eye, and no improvement with glasses. Visual fields not contracted. Tension normal in both eyes.

Ophthalmoscopic examination: "The nasal half of each optic disk is too red, the temporal half too pale. There is visible pulsation of both the retinal veins and arteries, extending to a comparatively long distance from the disks, and in some of the larger branches it can be traced as far as the equator of the globe. In the veins the pulsation is of the usual character, except in its intensity, and the extraordinary distance to which it can be traced from the disks. The arteries, however, seem to start up, and move as a whole with each impulse of the heart, without apparent change of calibre. As the arteries start forward, the veins contract; and as the veins fill out again, the arteries recede to their former position."

This patient was exhibited to the New York Ophthalmological Society, the pulsation of the retinal arteries, without glaucoma, or embolism, or organic disease of the heart, being considered almost unique.

He was injected with nitrate of strychnia at irregular intervals, until the 27th of April, the largest dose being gr. $\frac{1}{12}$. He was discharged with vision $\frac{20}{30}$ each eye.

Case XVIII.—W. C. P——, aged thirty-two years; came under observation February 6, 1877. Eyes began to blur on reading about eight months ago. At that time he could see well in the distance, but now he has difficulty in reading a sign across the street. Has long been in the habit of drinking and smoking without restraint.

R. V., $\frac{20}{30}$; L. V., $\frac{20}{80}$; no improvement with glasses. Eyes blur at times so that he cannot see $\frac{20}{200}$, and then suddenly clear up again. Urine normal.

Ophthalmoscopic examination: "Optic disks too pale, especially the left."

Stopped tobacco and spirits, and commenced the use of strych. nitrat. by injections.

February 9th.—R. V., $\frac{20}{20}$; L. V., $\frac{20}{40}$.

February 22d.—Is up to strych. gr. $\frac{1}{11}$. R. V., $\frac{20}{20}$; L. V., $\frac{20}{30}$.

March 1st.—Strych. nitrat., gr. $\frac{1}{8}$, produced slight dizziness.

March 2d.—Patient comes from a champagne supper, at which he drank wine and smoked nearly all night. He was ordered a Turkish bath, but did not report again.

Case XIX.—J. B——, aged thirty years; American, gentleman of leisure, married; complains (May 8, 1879) that he has been getting near-sighted. Drinks five or six times a day, and smokes at least four or five cigars daily. Guns and fishes much. Studies natural history and reads at night. Had rheumatic gout at nineteen or twenty. Six or seven years ago had chills and fever, and has since had occasional neuralgia of head and down back. Never had venereal disease. Urine normal. V. $\frac{5}{100}$ each eye. With $-\frac{1}{12}$, V. $\frac{10}{100}$ each eye. Visual fields normal.

Opthalmoscopic examination: "A soiled or dirty look of the optic disk and fundus."

To desist from tobacco and spirits, and to drink two quarts of milk daily.

May 26th.—The hypodermic injections of strych. nitrat. have been carried up to gr. $\frac{1}{8}$, and "stiffening of the jaws" has been produced.

R. $\frac{20}{200}$; L. $\frac{5}{200}$.

May 28th.—Vision $\frac{20}{200}$ each eye. Em.

June 20th.—Vision remains $\frac{20}{200}$ each eye.

Case XX.—D. A——, aged thirty-two years; bachelor; American, gentleman of leisure; has lived a very dissipated life from early youth, indulging freely in tobacco, spirits, and venery. Has had syphilis, and has several times been in a state of great nervous prostration from alcoholism.

Never had any trouble with eyes until about three weeks ago, when, having steered a boat twenty-two miles against a head-wind, the next morning his eyes were red and watery. They soon recovered from that attack, but four days ago a blur came over the sight of both, and is daily increasing. No pain in eyes, no headache. Had malarial disease thirteen years ago.

Smokes from ten to fifteen cigars daily, and is constantly in state of semi-intoxication.

R. V., $\frac{20}{80}$; L. V., $\frac{20}{126}$; no improvement with glasses. Reads J. 11 with both eyes at once.

Ophthalmoscopic examination: "Optic disks too pale."

Advised to quit tobacco and spirits, to drink freely of milk, to rub himself briskly from neck to heel with hair mittens and strap every morning, following the friction with a sponge-bath, and to take potas. bromid., gr. xx., every night on going to bed.

June 6th (two days later).—Vision unchanged. Had a night-sweat last night. Ordered quin. sulph., gr. ij., *ter in die.*

June 7th.—R. V., $\frac{20}{100}$; L. V., $\frac{20}{64}$.

June 13th.—Has taken Marburg's tincture, ʒ j., every four hours, and quin. sulph., gr. ij., every two hours, since four days ago, when his temperature rose to 103$\frac{3}{4}$.

June 16th.—Has had, besides the treatment mentioned, two injections of strych. nitrat., gr. $\frac{1}{24}$ each. R. V., $\frac{20}{40}$; L. V., $\frac{20}{64}$.

June 25th.—Has had daily increasing hypodermics of strych. R. V., $\frac{20}{40}$; L. V., $\frac{20}{50}$.

July 14th.—Took injections of strych. up to a week ago, when he had an acute development of tertiary syphilis, manifested by acute nodes on right tibia, and acute arthritis of right ankle-joint. Was put upon hydrarg. biniodid., gr. $\frac{1}{16}$, and sodii iodid., ʒ ss., *ter in die.* On the second day ran the iodide of sodium up to gr. xl., and continued at that dose for three days, and then dropped to one scruple three times daily.

Six days ago had a severe chill lasting three-quarters of an hour, followed by fever and profuse sweating, with headache. Gave quin. sulph., ℈j., between meals. Is now taking brandy, ʒ j., in each dose of Marburg's tincture.

R. V., $\frac{20}{20}$; L. V., $\frac{20}{32}$.

◆

Dr. Gresham, of Louisville, is (says the *Medical and Surgical Reporter*) ninety-seven years of age, and has just started for the mountains on his "last hunt." He is the only living fort-born native of Kentucky. When he came into the world his parents were dodging arrows and tomahawks, and his youth was spent with the rifle in his hand. He says he cannot die in peace until he shall once more have eaten venison of his own killing and cooking.

REPORT OF
A SUCCESSFUL CASE OF PARACENTESIS OF THE PERICARDIUM.

By JOHN B. ROBERTS, M.D.,

LECTURER ON ANATOMY AND ON OPERATIVE SURGERY IN THE PHILADELPHIA SCHOOL OF ANATOMY.

The notes of the following case of successful pericardial tapping have been furnished me by the operator, Dr. R. L. Payne, of North Carolina, and his son, R. Lee Payne, Jr. As my researches previously published have enabled me to find but twelve instances of paracentesis of the pericardium done in America, I feel it important to record this previously unreported instance of an operation easily performed, and not infrequently demanded, but usually considered as one requiring complicated apparatus for its accomplishment.

On July 1, 1880, E. P——, a colored man, about fifty years of age, consulted Dr. Payne and his son for dropsy. He had been treated ten years previously for a dropsical condition, but from this he recovered. In the spring of this year he had had a return of his trouble and now came for treatment. Examination showed the following conditions: Great œdema of the lower limbs, and considerable effusion in the subcutaneous cellular tissue, except upon the face. There seemed to be no ascites. He stated that he had had great difficulty in breathing, and that for two months he had not been able to lie down, but sat constantly in the open air. His respiration was so labored that it could be heard at a distance of a hundred yards. Physical examination of the chest revealed, by the usual diagnostic signs, a large accumulation of fluid in the right pleural cavity. No fluid was present in the left side of the chest, but some moist râles were heard in the left and at the apex of the right lung. The patient was expectorating some blood. The cardiac area of dulness was increased considerably, and the sounds were so muffled that it was almost impossible to distinguish them.

The diagnosis made was dropsy of the right pleura, and chronic pericarditis with effusion. The anasarca and hæmoptysis were considered as resulting from the heart-lesion.

He was placed on the fluid extract of jaborandi and the infusion of digitalis. At the end of a week there was no improvement, the suffering from dyspnœa was extreme, and death seemed imminent. As a last resort it was determined to aspirate the pericardium with the hypodermic syringe. The needle was introduced in the intercostal space between the fourth and fifth ribs, and previous to complete penetration of the intercostal muscles the syringe was exhausted of air. The needle was then pushed slowly and carefully on till it entered the pericardial sac, when the syringe was at once filled with a straw-colored fluid. The syringe was detached from the needle and emptied, and again applied and refilled with fluid. This was repeated until nearly an ounce of serum was withdrawn. That the needle entered the pericardium was considered certain, since it was seen that at every pulsation of the heart the needle made synchronous movements.

Great relief to the more urgent symptoms followed the operation, and the patient was able to lie a little lower than the half-recumbent position, which he had not been able to do for weeks. The dyspnœa was much relieved. Three days later the right chest was aspirated, a quart or more of fluid withdrawn, and the man thus enabled to lie flat in bed, breathe with ease, and sleep quietly. At the end of a week he was so improved that he was allowed to return to his home sixteen miles in the country. He was ordered infusion of digitalis with acetate of potassium three times daily. The patient was seen no more after this, but two weeks later he was reported as doing well, and was ordered to continue the same line of treatment. Four weeks later he died; but, as he resided some distance from Dr. Payne, the latter did not know of his death until a considerable period had elapsed, and then was unable to obtain accurate information concerning the immediate cause of the fatal result. Hence, no autopsy was obtained.

This interesting history illustrates what has so often been demonstrated, that the pericardium can be tapped with ease and certainty, and great relief given by the withdrawal of a comparatively small quantity of fluid. The use of the hypodermic syringe, which is practically a small aspirating pump, shows that no elaborate preparation or apparatus is required for the operation, which can be performed at any time with the ordinary appliances carried by every doctor. This instrument has been satisfactorily used in a similar manner by Dr. Porcher, of Charleston, S. C., and Dr. Paul, of Philadelphia. The case should be considered a recovery after paracentesis, for the symptoms were alleviated and the patient discharged from personal supervision.

Ordinarily, in cases of coexisting pleural and pericardial effusion, I would prefer to aspirate the pleura first, especially if there was a large quantity of fluid in that cavity.

This instance makes the thirteenth operation for paracentesis of the pericardium that has been performed in America, as far as I have been able to learn after diligent search for a number of years. Of the thirteen patients operated on, six have recovered and seven have died. The names of the operators, as taken from my paper read before the American Medical Association, and from my recently published monograph, are as follows: Warren, Norris, Lyon, Welch, Smith, Pepper, Douglas, Porcher, Paul, Staples, Porcher, Abbott, Payne. The operation, it will be seen, has been performed by Porcher twice.

It is to be hoped that others will follow the example of Dr. Payne, and not allow a patient to die from pericardial effusion because no aspirator is obtainable. The hypodermic syringe has almost superseded the exploring-needle as an instrument for diagnostic purposes, and, as is here seen, acts well in all cases where fluids are to be evacuated. I, myself, never think of using the old-fashioned grooved exploring-needle, but always prefer utilizing the greatly superior suction action of the hypodermic syringe, and have frequently employed the latter instrument in emptying small collections of fluid, such as are found in cysts and abscesses. In the case of suspected aneurism, the withdrawal of a few minims of blood with the hypodermic syringe will establish a certain diagnosis and enable the surgeon to act intelligently in the premises. It was first used in pericardial effusion, I believe, by Dr. F. P. Porcher.

A Bequest to Harvard College.—Edward M. Barringer, who died recently at Zurich, Switzerland, has bequeathed a large part of his estate to Harvard Medical College. The proceeds from the invested fund are to be devoted to the establishment of two scholarships, whose annual amount shall be not less for each than $200 or $300.

THE TREATMENT OF RECENT LACERATIONS OF THE CERVIX UTERI.

By G. H. BALLERAY, M.D.,

PATERSON, NEW JERSEY.

That laceration of the cervix uteri during labor is of common occurrence is proved by the frequency with which this lesion is met with in gynecological practice. Chronic laceration of the cervix uteri can only be cured by Emmet's operation, or "hystero-trachelorrhaphy," as Dr. Mundé calls it; but the object of this paper is to call attention to the efficacy of vaginal injections of warm water in the treatment of recent lacerations.

If the accident is not attended by profuse hemorrhage, and that in my opinion is the rule, it calls for no treatment for the first twenty-four hours; after that, the vagina should be syringed out thrice daily with warm water. After the third day a warm one per cent. solution of carbolic acid may be substituted for the plain warm water, especially if the lochia are in the least offensive. Under this treatment, *if the patient is kept quiet in bed*, a laceration of the cervix will heal in from ten days to two weeks. It is of the utmost importance that a diagnosis should be made in every case of laceration of the cervix uteri before the woman leaves her bed, for if this be done a cure can always, or at least generally, be effected by the simple means to which I have just referred. My own opinion is that spontaneous healing of lacerations of the cervix is the rule. I believe that there is more or less laceration of the cervix in every delivery at full term occurring in primiparæ, but the vast majority of these lacerations heal of themselves, if the patient does not leave her bed until the tenth day. If the woman gets up on the fourth, fifth, or sixth day, as commonly occurs among the poorer classes, the uterus being large and heavy, sags down in the pelvis, and traction is exerted by the vaginal walls upon the lips of the cervix, which are thereby everted and subjected to constant friction against the vaginal walls by every movement of the woman. By this constant irritation the mucous membrane of the cervix becomes eroded, the circulation through the uterus becomes interfered with, and chronic engorgement and subinvolution are the result.

Together with these morbid conditions, more or less displacement generally coexists, and in my experience anteversion or anteflexion is the most common form. In order to prevent this train of evils, it is necessary to recognize early the initial lesion. Therefore, in my opinion, it should be a *rule*, in private practice as well as in all lying-in hospitals, not to allow a patient to leave her bed until *after the ninth day*, and that in *every case* the cervix uteri should be carefully examined with Sims' speculum before the woman is allowed to assume the upright position. If an unhealed laceration is found to exist, she should be kept in bed for a week or ten days longer, during which time vaginal injections of plain warm water, or a weak, warm solution of carbolic acid should be used thrice daily. I append a brief report of three bad cases, which will serve to illustrate the beneficial effects of vaginal injections of warm water in recent lacerations of the cervix uteri.

Case I.—In February, 1876, I was called into the country to deliver a woman that a medical gentleman had been endeavoring for several hours to deliver with forceps. I found everything covered with blood —floor, bedding, instruments, and doctor. I found the head still at the superior strait, but the caput succedaneum was pressing on the perineum. The cervix uteri was badly torn in four places, and there was laceration of the posterior wall of the vagina. The woman's pulse was 130, and feeble, and her countenance anxious and haggard; she was a primipara and had been in labor thirty-six hours. Chloroform was administered, and I applied Elliott's forceps and brought the head through the superior strait. I was proceeding with great caution, and there was as yet no great distention of the parts, when the swollen portion of the scalp suddenly made its appearance through a central rupture of the perineum, at a point corresponding to the laceration of the vagina. I thought that I might still be able to bring the head through the vulva, but in that I was foiled; and the perineum was torn from the vulva to the anus. Profuse hemorrhage from inertia followed, and the most energetic treatment was required to save the patient's life.* After the uterus had been made to contract firmly, the hemorrhage ceased, and after reaction had been established by stimulants I left the patient. Two days later I again saw the patient, and finding her general condition fair, I sewed up the laceration of the perineum in the hope that union *might* result; but I must confess that I had no *great expectations* of success. The result was perfect union. Vaginal injections of warm water were used twice daily from the second day after delivery until the twelfth. Three weeks after delivery I had an opportunity to examine this patient, and I found the lacerations of the cervix perfectly healed.

Case II.—Mrs. W——, aged twenty-nine years, was delivered with forceps, by an irregular practitioner, of her second child, in June, 1879. The perineum was torn through the sphincter ani, and the laceration extended about two inches up the rectum. Two days later she was seen by another medical man, who called my colleagues, Drs. Marsh and Blunden, in consultation, and by their advice she was admitted into St. Joseph's Hospital, under my care. The patient's general condition was bad, and as the edges of the laceration and the lochial discharge presented an unhealthy appearance, I decided not to sew up the perineum, as in my judgment it would have been useless. The patient's strength was supported by tonics and nourishing food, and vaginal injections of warm water were used every four hours for the first three days, then every six hours. After the third day a weak carbolic acid solution was substituted. A week after her admission I examined the uterus with Sims' speculum, being careful not to exert much traction on the bowel, and found a deep stellate laceration of the cervix. The vaginal injections were continued twice daily, and at the end of three weeks after delivery the laceration had perfectly healed. Five weeks later I operated on the perineum with a successful result.

Case III.—Mrs. W——, aged twenty-eight years, was delivered of her first child in January, 1879. Her labor was long and tedious, the membranes having ruptured prematurely. Her medical attendant, a very intelligent and skilful practitioner, finding that the tissues of the cervix and the vagina and vulva had rather suddenly and unexpectedly become œdematous, and that her pulse was becoming frequent, applied the long forceps and delivered her. Notwithstanding great care in the delivery the cervix uteri was badly torn, and the perineum was lacerated through the sphincter ani. The greater part of the laceration of the cervix in this case was caused merely by the introduction of the blades of the forceps; in fact, the doctor informed me that in passing his finger between the cervix and the child's head, in making an examination, after œdema of the parts occurred, that the cervix tore like a piece of wet paper. Vaginal injections of slightly carbolized warm water were commenced within twenty-four hours after delivery. I saw the patient with her medical attendant nine days after delivery, and found that the cervix had been deeply torn in four different directions; the parts, however, had a healthy appearance, and it was evident that the lacerations were healing. The vaginal injections were continued for ten days longer, at the end of which time the lacerations in the cervix had healed. The perineum was subsequently operated on with success.

Reports of Hospitals.

PENNSYLVANIA HOSPITAL, PHILADELPHIA.

Clinic of J. M. Da Costa, M.D.,

PROFESSOR OF THEORY AND PRACTICE OF MEDICINE, AND OF CLINICAL MEDICINE IN JEFFERSON MEDICAL COLLEGE HOSPITAL.

(Special Report.)

I. REMARKABLE SPECIMENS FROM A CASE OF ULCER OF THE STOMACH.

II. CHRONIC GASTRITIS SUCCESSFULLY TREATED BY WASHING OUT THE STOMACH.

I shall first call your attention to these specimens from a case that was in the hospital only for a few days before his death. Owing to this man's very scanty knowledge of the English language it was impossible to obtain anything like a complete history of the case. We discovered enough, however, to connect the clinical evidence during life with the remarkable results of the *necropsy*.

J. P——, aged fifty-five years, an Italian, spoke nothing but his native language; a plasterer by trade; was admitted on the first of November in an extremely prostrated condition. Of his previous history, partly owing to his inability to communicate with us, and partly owing to his debility, we could only ascertain that he had been intemperate in his habits and had suffered from general dropsy for a space of two months some twelve years ago. His dropsy was then said to be caused by kidney affection, but the evidence that this disease had much to do with that of which he died was not very strong. After this dropsical period his health remained good until six months before his admission, when his appetite began to fail, and he was troubled with indigestion, flatulence, and dyspnœa, and experienced a burning pain in the pit of his stomach. For the last two months these symptoms of pain and indigestion have been complicated by vomiting, especially in the morning, and occasionally at other times. This vomiting grew in intensity, and lately has become constant, so that he rejects everything; not only solids, but also liquids. We never saw blood in the matters ejected, yet he said that on a few occasions the vomit had a coffee-ground appearance. Bowels were very constipated. He had no motion at all during the six days prior to his admission.

His condition upon admission was one of great emaciation; of extreme suffering from pain. His face was all drawn to one side and his complexion straw-colored. His conjunctivæ were slightly stained and he seemed older than his years. There was a marked *arcus senilis*. His abdomen was resistant, and rather full, and there was tenderness at the epigastrium. I could detect no tumor. The fulness of the abdomen seemed to be due to the fulness of the recti muscles. There were very offensive eructations, with fetid vomit and glairy mucus. The tongue was dry and red, but not much coated. He was very weak.

---

* That the hemorrhage was due to inertia and not to the lacerations, was proved by the fact that contraction of the uterus stopped the hemorrhage and relaxation was followed by profuse bleeding.

He remained in the hospital for a few days in this condition. Our attempts at nourishment were not successful. He threw up all the milk and lime-water which we gave him, and even the beef-tea. A moderate amount of stimulus, however, was retained. We tried to discover whether the entrance of food into the stomach produced pain, but it was hard to reach any conclusion regarding this point. A turpentine injection moved the bowels, giving rise to the evacuation of large masses. He rapidly grew feebler, a profuse sweat broke out, and he died in a state of collapse, the vomiting having prevailed to the very last, but there was no discharge from the bowels. I wish to call your attention to the remarkable results of the *necropsy*.

Liver.—Small, dense, fatty—the liver of an intemperate man. There was a slight increase in its fibrous texture, with fatty degeneration of the hepatic cells.

Kidneys.—Somewhat harder than normal, but no degeneration of their structure. Urine examined repeatedly with negative results.

Heart.—Flabby, somewhat fatty.

But what symptoms had there been during life indicative of the remarkable lesion of the stomach disclosed by the *necropsy?*

Stomach.—Cutting it open at the cardiac extremity we found it slightly dilated, with very thin walls, and, as we progressed toward the pyloric extremity, we came across a big hole (this is really the most expressive explanation which I can give of its appearance), due to a large ulcer which had laid bare and eaten away the muscle and the peritoneal covering, so as to establish a communication with the large intestine. It was an extraordinarily large perforating ulcer, communicating between the large intestine and the stomach.

Now, we have an explanation of the vomiting, pain, and occasional coffee-ground appearance of the vomit. This explains why we were not able to detect the presence of any tumor (we had suspected cancer of the stomach). It is very strange that there was so little intestinal irritation. The history does not mention it at all; on the contrary, the constipation was constant through life, and the *necropsy* showed no peritonitis. The ulcer evidently did not cause much disturbance.

Regarding the *character of the ulcer*, I do not think it is cancerous. The absence of thickening and of growth are against the idea of cancer. I will tell you at our next meeting what the microscope reveals. The stomach symptoms were marked, and the intestinal symptoms obscure. There is no evidence whatsoever of peritonitis.

DILATATION OF THE STOMACH.

You remember that this patient was before you last year. We were then treating him for dilatation of the stomach. You remember that our treatment consisted in washing out the organ thoroughly with a slightly alkaline solution. As the patient is again in the hospital I have thought that you would be interested in seeing him once more. You recollect what remarkable success attended our treatment by washing out the stomach after we had tried all kinds of alteratives and tonics. We repeated this process of washing out every second day for three or four weeks. At the same time we gave small doses of nux vomica. Under this *régime* he gained flesh, the vomiting ceased, and he was able to digest his food. He remained well until quite recently, after leaving the hospital. He comes back with some of the same symptoms, but not in the same degree. He is also suffering from a large irreducible hernia.

The question which presents itself with regard to present treatment is: shall we resume the washing-out process, or, as the gastric symptoms are not so very prominent, shall we first try other methods before we subject the patient to this? On the supposition that this case is one of chronic gastritis and atony let us first try eight drachm doses daily of the tincture of nux vomica in water. At the same time his diet shall be strictly regulated. He must avoid potatoes, and take only a certain amount of solid food, such as underdone meat, oysters, and milk with lime-water. After every meal he had better take ten grains of saccharated pepsin.

Progress of Medical Science.

ANEURISM OF THE ARCH OF THE AORTA CURED BY REST, RESTRICTED DIET, AND IODIDE OF POTASSIUM AND ERGOT.—Dr. R. Sutton communicates to the *American Journal of Medical Sciences*, October, 1880, a case of aneurism of the arch of the aorta, in which a cure was effected by rest, restricted diet, and the administration of iodide of potassium and ergot. The patient, female, aged twenty-one years, was seized with a violent pain in the region of the heart while at work, and for six months afterward was subject to repeated attacks of pain and frequently fainted. Dr. Sutton saw her for the first time about nine months after the seizure, and an examination revealed an aneurism of the descending portion of the arch of the aorta. The ribs were bulged up above the plane of the chest-wall; the thrill was very loud, and the impulse was visible in the second intercostal space. She remained under treatment for one year. During this time she was secluded from all excitement, and took, three times daily, from ten to twenty drops of fluid extract of ergot and five grains of iodide of potassium. She was also put to bed at absolute rest for five and a half out of every six hours—the half-hour being allowed for quiet walking about the room. Her nourishment was restricted to ten ounces of material, fluid and solid together, for each twenty-four hours. This regime was strictly adhered to for thirteen months. At the end of this time she was reduced to almost a skeleton, and an examination revealed the fact that the aneurism was cured; the action of the heart was weak and irregular, with a distinct anæmic bruit. From this time her nourishment was increased, drachm doses of bitter wine of iron were given, and she was allowed to be up and down at will. Her cure appears to be permanent. At a meeting of the Allegheny County Medical Society, held June 15, 1880, the patient was examined by a committee, which reported that the aneurism was cured, and that the only evidence of disease at the time was a slight endocardial murmur.

On the Cause of Bad Odor of the Feet, with Directions for Treatment.—Dr. George Thin, in the *British Medical Journal*, September 18th, asserts that the cause of the bad odor which is sometimes associated with excessive sweating of the feet is to be found in the coverings of the feet, and not in the sweat itself. In his experiments, which were reported to the Royal Society, he discovered that the reaction of the moisture in the stocking and in the sole of the boot was alkaline, and that the reaction of the moisture exuding from the skin of the sole of the heel was faintly alkaline, whilst that of the perspiration of other parts of the body was acid. The fluid from the sole of the heel was thus shown to be not pure sweat, the faintly alkaline reaction being doubtless due to the serous discharge accompanying the eczema set up by the local hyperidrosis. The fluid in the sole of the stocking was found to be teeming with bacteria forms—*Bacterium fœtidum*. The rapid development of bacteria in the fluid which exudes from the soles is doubtless favored by the alkaline reaction produced by the mixture of serous exudation with the sweat. The following treatment was found to be effective: the stockings were changed twice daily, and after taking them off, the stocking-feet were placed for some hours in a jar containing a saturated solution of boracic acid. They were then dried, and were fit to wear again if desired. The boracic acid effectually destroyed the smell. But to kill the bacteria in the stocking was not enough. The leather in the bottom of the boot is wet and sodden, and smells as vilely as the stocking. This difficulty was removed by the use of cork soles. A pair must be worn only one day unchanged; at night they must be placed in the boracic jar, and be put aside the next day to dry. The boracic acid solution is an excellent application to the painful skin in these cases; when the tender skin of the soles is washed with it, a sensation of coolness succeeds the feeling of heat and tension which are the usual accompaniments of the eczematous condition associated with the smell, and the skin becomes harder and loses its abnormal redness.

Fracture of Ninth Dorsal Vertebra, with Partial Dislocation—Recovery.—Dr. H. Hickman, of St. Louis, reports a case in the *St. Louis Medical and Surgical Journal*, Sept. 20, 1880, where there was every reason to believe the injury to be a fracture with partial dislocation of the ninth dorsal vertebra. There was no sign of paralysis. Patient, aged thirty-eight years, a brewer, while hoisting a bucket of ashes, was precipitated into a cellar, a distance of ten feet, in consequence of the breaking of a pulley-bracket, and was found on the floor doubled up and unconscious. Upon examination a considerable displacement was noticed, which was shown by a marked depression superiorly with a corresponding projection below; besides this, the soft parts on either side of the injured spine had developed into tumoid prominences, affording ample proof of the immense strain they had been put to. The patient was at once lifted by the shoulders almost off his feet, while steady, increasing pressure with the thumbs was applied. This soon appreciably reduced the dislocation, and a compress and bandage were applied, and the patient put to bed. He suffered from an exceedingly acute pain at the base of the neck and upper part of the chest, but had very little pain at the seat of the injury. The next day he was able to micturate, and the soft parts having almost resumed their normal outline, a plaster-jacket was applied. The patient was posed on his hands and knees during the ten minutes required for the necessary bandaging, and although then suffering acutely, his pain subsided as soon as the plaster hardened, and never returned while he wore it. The bowels remained torpid for six days, but this being a very common occurrence among brewers, who, on account of accident or for other good reason, are suddenly denied their usual very liberal allowance of beer, it was not thought to be due to any direct result of the injury. Five months after the accident the only signs of the injury were a bifurcation of the dorsal groove at the site of the fracture, and a very slight swell of the posterior curve of the right thoracic wall rising above the line of injury. The jacket was reapplied but once during these five months.

Treatment of Infantile Diarrhœa by Powdered Charcoal.—Dr. Guérin, in referring to a recent communication to the *Académie de médecine*, made by Bouchardat, remarks that for a long time he has been in the habit of combating infantile diarrhœa by mixing the milk in the suckling-bottle with charcoal powder. He usually adds half a teaspoonful of the powder to one bottle of the milk. The infants take the milk readily, and in a few days the greenish stools of the little patients change to a dark yellow, while their consistence becomes increased. In addition to the admixture of powdered charcoal, the milk is diluted by one-half or one-third of its bulk of sugared water. He has frequently seen intractable summer complaints yield in a few days to this treatment.

Note on Vulvar Eructation.—This phenomenon, which consists in a noisy expulsion of gas from the vagina, has been observed by Dr. Löhlein in 8 out of 750 gynecological patients. The conditions for its production are, according to him, the introduction of air into the vagina in consequence of insufficient vulvar occlusion and under the influence of an excess of the atmospheric pressure over the intra-abdominal pressure, and the expulsion of this air under the influence of a sudden augmentation of the intra-abdominal pressure. He thinks that we have to deal in these cases with atmospheric air, and not with gas developed in the vagina or coming from the intestines. The conditions which render the vulvar occlusion insufficient are: 1, lateral fissures of the posterior part of the vulva when combined with a limited development of the labia minora and majora; 2, an excessive laxity of the vaginal walls, combined with a slight rupture of the perineum. In none of the cases was there a deep rupture of the perineum. The positions of the body most favorable to a production of the phenomenon are those which diminish the intra-abdominal pressure, such as the knee-elbow position, the decubitus on one side of the belly, the dorsal decubitus with the arms raised above the head, the act of rising suddenly in bed, etc. The phenomenon was always met with during the first week after labor. The treatment consisted in closing the vaginal fissures by sutures and in astringent injections.—*Lyon médical*, September 5th.

Seats for Saleswomen.—The four representative dry-goods houses in Philadelphia, employing from one hundred and fifty to two hundred women each, as clerks, now provide seats for their saleswomen when not engaged with customers. A number of smaller establishments have imitated their example. The employers report that the plan works excellently.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

PHYSIOLOGICAL EDUCATION.

It was the custom up to one hundred and fifty years ago to keep young infants so tightly swathed and bandaged that they could scarcely move their limbs at all. When Rousseau wrote his "Emile," a work which started a revolution in educational methods, he began by attacking this pernicious practice of infant bandaging. It was not only a physical evil to the child, but it typified well the narrow and distorting influences which the priestcraft and statecraft threw over the education of the young at that time. Rousseau advanced a new and startling idea: it was to give the child the utmost freedom in education: to teach him those things only which he liked; to develop and improve those tendencies which the child spontaneously displayed; to put nature first and books last. This idea, though nearly smothered with accompanying exaggerations, was taken up by others; it has of late years been developed in the kindergarten system of Germany and the *salle d'asyle* of France. And now we see it still more fully expanded in the prevalent discussions upon "scientific" and "physiological" systems of education. There has been no abler advocate of physiological education than the late Dr. Edward Seguin, whose principal work upon the subject has just reached its second edition.* Dr. Seguin's book, however, is but one of the indications of a wide interest in the subject. There have been sharp assaults upon our cherished common-school system from many quarters. Literateurs, political economists, school-superintendents, and scientists have all had their say against it, and, though the agitation may have brought out some exaggerations, we find in it a sure evidence that some change is needed and will take place.

This new movement for educational reform has an interest to the physician, since it aims to bring into greater use among teachers and pupils that knowledge with which he is especially familiar. The aim of the physiological method in education is "to train all the organs to accomplish their functions in the most physiological manner; and to elevate all the functions which are under the control of consciousness to the rank of intellectual capacities, and make them concur in the operations of the mind and of the will." The methods by which this is to be accomplished are, in part, the extension to the common school of certain of the features that characterize the kindergartens. Instead of the present Procrustean system, by which a fixed number of rules, definitions, and facts are dosed out to be taken by a fixed number of boys and girls in a certain fixed time, each study is to be adapted to the child and presented to him in such a way that he learns it with actual pleasure. Base-ball and arithmetic, writing and skating, are to come with equal ease and satisfaction to the learner.

This may seem a very utopian idea, though even if it be so there is no doubt that a place for education considerably this side of utopia would be better than its present one. The agitation for a physiological education indicates a tendency to secure more science for the teacher and less ill-judged compulsion for the scholar. And so far it is a healthful tendency and one to be encouraged. There are in it two features that especially deserve the attention of physicians: It is part of the new system, first to see that the sanitary condition of the school-room and the physical well-being of the child be kept at their very best; and, second, to see that the special senses and bodily dexterities be developed to the highest point possible. The sanitary condition of the schools is a subject that need not be discussed now, though wanting attention badly enough. But the question of how much can be done for the mind, by a proper training of its special servants, is one deserving much more study than it has yet received. Dr. Seguin argues strongly for the greater employment of this kind of training, and he would begin with the unborn child and teach the mother to beware of those physical or emotional activities which may affect her offspring. He would have the infant lie as much on the right side as on the left, in order that the right brain may not be compressed. Acting upon the theory that man has two brains, he would make him ambidextrous, so, perhaps, helping to develop both hemispheres. Training the eye, the ear, teaching habits of observation, making the pupil acquire some special dexterity of hand or body, all these methods lead, it is claimed, to brighten and expand the intellect, and to make the man fitter to perform his work in life.

It can be easily seen that this sense-education must be of value in the mental development of the child. In determining how great this value is, the observations of the intelligent physician can be of great assistance. We do not believe, for our part, in carrying too far this system of object-teaching and sense-education. There must still be such a thing as discipline and text-books; the latter tell, perhaps, in a few pages, the results of the studies of many years, and the observations of thousands of persons. Undoubtedly our common schools need a change—but not too much of Rousseau.

---

* Report on Education, by E. Seguin. United States Commissioner on Education at the Vienna Universal Exposition. Milwaukee, Wis.: Doerflinger Book and Publishing Co. 1880.

DIPHTHERIA AND SCARLATINA.

The statistics of the Bureau of Contagious Diseases show an alarming increase in the number of deaths from diphtheria and scarlet fever. During the past two months the cases of scarlet fever which were reported have ranged from fifty-four weekly, at the commencement of the period, to one hundred and fifty-one for the week ending December 4th, the percentage of deaths being twenty and a half. The diphtheria cases for the same time commenced at ninety-four weekly and ended at one hundred and sixty-seven, with forty-six per cent. of deaths. From these figures it would appear that about one in every five cases of scarlet fever, and more than two in every five cases of diphtheria, succumb to the disease. This would make the prevailing type of the former disease very severe, while that of the latter would be malignant. But in reality we can safely assume that such is not absolutely the case in either instance. The proportion of deaths to the cases reported is unusually large. The only way to reconcile this apparent discrepancy is to accept the fact that all the cases are not reported, and that consequently the diseases are very much more prevalent than the figures of the health-bulletin would lead us to suppose. We believe this to be true, judging from the testimony of some practitioners who are attending large numbers of cases of both diseases, and who habitually neglect to report them to the board, unless compelled to do so by a death certificate.

Considering the widespread prevalence of both diphtheria and scarlet fever, the types of the diseases are not unusually severe at present. But this is by no means a subject for congratulation at this early season, in view of the reasonable possibility of the increase of both diseases during the winter and spring, and the probable increase of their malignancy. Very few physicians have lost fifty per cent. of their cases of diphtheria thus far. Even twenty per cent. would be a very high figure. Still the prospect of the continuance of this comparatively low ratio of mortality is far from promising. At least, the wise practitioner must be on his guard, and do everything he can, not only to treat promptly and efficiently all cases in hand, but prevent their increase. It is true that the community is reasonably well educated by the health authorities concerning the contagious character of these diseases, but it is essentially the province of the attending physician to emphasize the injunctions of the board by giving some personal attention to preventive measures. At the outset of an epidemic of both these diseases, this advice should have more than its usual force. Whatever can be done by the physician to narrow the chances of the spread of the contagion, lessens the chances of mortality even in mild epidemics. Concerning the spread of both diphtheria and scarlet fever there are certain well established causes. Whether one can believe in this or that theory of infection is not essential. The physician can always afford to be on the safe side by giving his families the benefit of the doubt. To this end he should see to it not only that the houses are properly ventilated, but that the privies, water-closets, drains, and cellars are in good condition. A personal inspection regarding these points has so often been rewarded by tracing the causes of disastrous mortality in certain houses that no special pleading is needed for it. A knowledge of principles of good plumbing and proper drainage is as essential to the physician as is that of any other preventive of disease. None of these factors in the problem of contagion are beyond solution, and oftentimes the physician is the first one to grapple with them in the interests of the life and health of those under his care.

The danger of the propagation of both diseases in the schools will readily suggest itself. While it is proper to state that the Health Board does all in its power to reduce the chances of the spread of diseases in them to a minimum, its efforts are far from being successful. It is true that the moment cases of contagious diseases are reported the number of the houses in which they are contained are sent to the schools of the district, and children of the same or different families, residing in said houses, are sent home. But in fifty per cent. of these cases the mischief travels ahead of its supposed prevention. There is every incentive for those inclined to spread disease to conceal its existence in their families, and this is at the foundation of all the difficulty with which all health boards must contend, and which difficulty it is virtually impossible to circumvent under existing circumstances, except by the special aid of the physician in attendance.

While referring to the duties of the physician, relating to the prevention of these diseases, it is unnecessary to say that said duties extend to other contagious maladies, notably to small-pox, which is cropping out in an ominous way in our city. In regard to the prevention of this disease there is now a special responsibility which is thrust upon the physician in advising vaccination for all unprotected persons, and revaccination for all doubtful subjects. Not only are contagious diseases quite prevalent in this city, but they are showing themselves to such an extent in different parts of the country, that our remarks have more than a local application. Thus far diphtheria leads the rest. That it will probably continue to do so goes without the saying. With the increased opportunities for studying its etiology and pathology it is to be hoped that some new facts will be added to the history of this dreadful disease, which may help us to treat it to better advantage and lessen what now appears to be its inevitable rate of mortality.

QUACK ADVERTISEMENTS IN THE RELIGIOUS PRESS.

The religious press takes such high ground in moral as well as spiritual matters that it should be above the suspicion of wrong-doing in the ordinary affairs which concern the worldly-minded; and yet that this is not always the case we have frequent and melancholy examples. Not the least of these latter are the publication of the most objectionable quack advertisements, under the cover of a general guaranty that everything which appears in the paper is in keeping with its character as a high-toned religious journal. And yet this is done in almost every religious periodical that reaches us. On one side of the page of such a journal we read of the growth of Christianity, and of its benign influence upon the heathen, and on the other side is the advertisement of a blood-purifier, and of its good offices in curing "biliousness," "dyspepsia," and "liver complaint." In one column is a tirade against lotteries, claiming that it is "a shame and grievous wrong that the government itself should be the minister of these demoralizing institutions," and in another place are published a number of certificates of bogus and impossible cures from a notorious quack advertiser. In the same editorial occurs this statement, made in evident good faith, and with the laudable intention of making a telling point: "It is one of the curiosities of human nature that men will on one page of their newspapers advocate good morals, and on another page pander to the pernicious and ruinous propensities of their fellow-men." We advise the editor of the *Observer*, if he would be consistent, to look after the quack advertisements in his paper.

MLLE. BERNHARDT AND HISTRIONIC DEATH.

Doubtless those physicians who saw Mlle. Bernhardt during her recent appearance in this city will admit that there is much of pathological as well as of dramatic interest in her various performances. It is currently reported, in the first place (though we do not credit the story), that the renowned actress is in either the first or the second stage of phthisis. It is undoubtedly the fact that she works extremely hard, and sometimes to the point of syncope. If she has not phthisis, the etiology of her extreme attenuation furnishes a most suggestive topic of inquiry. As she is reticent upon this subject, however, the pathologist can only speculate, noting meanwhile how much better artistic millinery acts in relieving emaciation than cod-liver oil.

The phenomena of most absorbing interest, however, connected with Mlle. Bernhardt are her modes of dying. These, up to the present time, are of six different kinds, and present rich opportunities for a study of the moribund condition. The causes of the deaths, so far as our analyses go, may be, as usual, divided into two classes: the remote and the immediate. The former cause seems always to be connected with an acute hyperpyrexia of the emotions. The fair *moritura*, while suffering from this disturbance, is treated with, as it were, the cold plunge. In other and less figurative language, there is generally some fiend in red tights or domino, who, by craft or violences, induces a solution in the continuity of previously happy *affaires du cœur*, the result being dismay, despair, suicidal frenzy, and finally the moribund condition now under discussion.

The immediate causes of death are various, and here we find the best opportunities for pathological study. The artist dies by poisons, by (presumably) hemorrhage from incised wounds, or by injury of vital parts; and sometimes, it seems, by a direct inhibition of vital processes incident to the intensity of the emotional excitement or the subjective violence of the suicidal purpose. The artist presents, therefore, at different times the symptoms of vertigo, blanching of the face from vaso-motor inhibition of the arterioles (and possibly face-powder), irregular cries, convulsions, both clonic and tonic, and finally syncope, the latter occurring generally on a soft Persian rug, or a sofa.

These symptoms, as a rule, receive no treatment, unless the homage of tears and applause from the audience be considered such. On no occasion is a medical man called in, which is obviously a departure from realism and good sense, if not from high art. For it is true that some of the convulsions look as though they might be controlled by appropriate treatment. We wish simply to analyze, however, and not to criticise the subject before us.

Mlle. Bernhardt's deaths are remarkable, artistic, and effective. We must confess to having seen few in real life that moved us so deeply. The death-struggles, we may say, were remarkably life-like, in a certain sense. We have never seen their equal in real death. We can recommend the profession to study the phenomena of the histrionic death as shown in Mlle. Bernhardt; for a physician may practise all his life and never see anything like them.

DRUGGIST AND PHYSICIAN.

At a recent meeting of the Philadelphia County Medical Society, the relations of the druggist and physician was the topic for discussion. A great deal of interest was evinced, and the propriety of physicians dispensing their own medicines, in order to prevent unauthorized renewals of prescriptions and overcharging by druggists, was maintained by a number of the speakers. It was stated that a physician who dispenses his own drugs is ineligible as a Fellow of the College of Physicians of Philadelphia, but this is evidently a mistake. The whole question of the relations between druggists and the medical profession, and the proper steps to be taken to secure co-operation of both professions in correcting present abuses, was referred to a committee, corresponding, we suppose, to the Comitia Minora of the Medical Society of the County of New York.

Reports of Societies.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, November 18, 1880.

Fordyce Barker, M.D., LL.D., President, in the Chair.

The Librarian's report announced the reception of eight bound and one unbound volumes, twenty-five pamphlets, and sixty-six medical journals since the last stated meeting.

The Statistical Secretary, Dr. Francis V. White, announced the death of Brigadier-General Richard S. Satterlee.

Dr. T. Herring Burchard then read a paper on

OPERATIVE INTERFERENCE IN ACUTE PERFORATIVE TYPHLITIS.

The paper was based on observations made in four fatal cases which had fallen under his own observation, and its chief point of interest was in the answer to the question: "Is this disease necessarily fatal?" He regarded it as surprising that some definite plan of treatment should not have been devised before this, for an affection the anatomical lesions of which were of such a nature as not to preclude surgical interference. All hopes from the use of medicinal agents had been buried in the uniformly fatal termination of the disease. He therefore suggested that by timely surgical interference there was reasonable hope of saving a certain proportion of lives. His plea was based upon the following propositions:

1. The lesion in acute perforative typhlitis is not necessarily fatal; but it derives its fatality from the rapid development of intercurrent fatal complications: first, shock from perforation; second, peritonitis from extravasation of fæces.
2. The patient once resuscitated from shock is yet imminently menaced with peritonitis.
3. The irritant action of extravasated fluids upon the peritoneum being well-known, was it not one of the surgeon's responsibilities to relieve the peritoneum of that source of irritation prior to the development of acute fatal inflammation?
4. Lumbar typhlotomy, properly performed before the development of peritonitis, should give additional chances for life.
5. While the proposed operation, performed under such desperate circumstances, could not be expected to furnish average successful results, nevertheless, its mortality should not be an argument against its employment, if thereby a single additional chance for life was offered.

Dr. Burchard then referred to many reported cases of wounds of the intestines in which recovery had taken place, notwithstanding the large openings that had been made; and regarded it as singular that injuries of such gravity could be recovered from, while minute perforations in the appendix vermiformis were so fatal. Doubtless the fact could be partially explained by the existence and inversion of the mucous membrane in the former instance, and their absence in the latter, which permitted the immediate extravasation of fecal matter into the peritoneal cavity.

About twenty per cent. of those patients were killed by the shock, and in some of the remaining he believed that recourse to surgical interference *before the advent of peritonitis* might be proper. With reference to diagnosis, the disease had no pathognomonic symptom; but the history of the case, coupled with the symptoms developed, afforded fair presumptive evidence of its existence. In nearly all the recorded cases of perforation there was a history of *previous attacks of cæcal* distress or of well-marked typhlitis, more or less severe. *Pain* to be significant must be developed acutely and be localized. Shock was a third prominent factor in diagnosis, and ranged from syncope at the onset to overwhelming collapse.

Dr. Burchard then read the histories of the four cases which he had observed. For this class of cases he remarked that the ordinary operation for the evacuation of a perityphlitic abscess would be useless, and proposed an operation to be performed in the following manner:

"Guarded by every antiseptic precaution, why not in such cases cut down on the perforated appendix from the side, as in Amussat's operation? Wash with antiseptics the adjacent peritoneal surfaces, so cleansing them from all irritating exudations, secure by stitches the ulcerated appendix to the mouth of the wound, and so afford free and perfect external drainage.

"The operation is readily performed. The appendix is most easily reached by a transverse incision, commencing two inches in front of the anterior border of the longissimus dorsi muscle, and extending forward about six inches parallel to and just above the crest of the ilium. Integument, fascia, and muscles are carefully divided, until the peritoneum is reached; this is opened, and the posterior surface of the cæcum and the appendix are exposed.

"Performed at an early period, before the occurrence of general peritonitis, and under the protective influence of antisepsis, that the dangers of septic poison may not be added to dangers already existing, I believe that this operation offers a better chance for life than any procedure at present practised for the relief of this terrible disease."

The opinions of several eminent surgeons were then given in support of the proposed method.

The paper being before the Academy for discussion, the President referred to two cases in which error in diagnosis occurred, one being diagnosticated as perforative typhlitis, but autopsy proved it to be a case of pelvic hematocele; the other being diagnosticated as pelvic hematocele, but proven by autopsy to be one of perforation of the appendix vermiformis.

Of course the proposed operation would be out of the question in cases of pelvic hematocele, but how could the differential diagnosis be made, even in the light of modern science; and it was with the view to eliciting opinions upon that point that he reported two cases, as follows:

In 1852 a young lady, the daughter of a physician, while returning home from church, was suddenly seized with pain in the right iliac fossa. It was very near to the period of menstruation, and before she reached home there was some bloody discharge from the vagina, but none afterward. The pain was severe, and was followed by shock, and subsequently intense peritonitis developed, first local and then general, and within forty-eight hours she died. Soon after she was brought into the house, Drs. J. Kearney Rodgers and Reese reached the case, and within a few hours Drs. Carnochan and Barker were added to the council. It was the opinion of all the gentlemen that the case was one of perforation of the appendix vermiformis. At autopsy neither inflammation of the cæcum nor perforation of the appendix were found, but pelvic hematocele and general peritonitis.

In 1872 the wife of a physician was seized suddenly with intense pain in the right iliac fossa, there was a discharge of blood from the vagina, and peritonitis quickly developed, and she died on the second day after the attack. Dr. Barker, with three or four others, deservedly eminent, saw the patient, and there was considerable tumefaction in the right iliac fossa, with great tenderness and severe pain, excessive tenderness of the vagina, and the uterus could not be moved on account of its increased size and tenderness. Dr. Barker's diagnosis was pelvic hematocele, and in that opinion all the consultants joined. At autopsy no extravasation of blood was found into the pelvic cavity; the uterus contained a very young ovum; the cæcum was filled with fæcal matter, some of it very hard; the appendix was at least three times its normal size, had a distinct perforation as large as a very large pin, and fæcal matter had escaped into the peritoneal cavity.

Dr. L. Weber remarked that the statements of the surgeons which had been quoted by the author of the paper, in support of the proposed operation, could not be applied to that operation, because they were the opinions of those surgeons concerning an operation entirely different from the one under consideration—namely, for the relief of intestinal obstruction. The proposed operation Dr. Weber regarded as prophylactic in character to a certain extent, and under such circumstances he thought it a matter of very great difficulty to decide whether or not, in a given case, it should be performed. To illustrate: in *four* cases which had fallen under his care, and in which an operation was performed successfully at a later period, one on the eleventh, one on the ninth, and two on the seventh day after the first symptom developed, all the patients recovered. In one of the cases the patient had suffered from distinct colicky pains for one or two years before the final attack occurred in the right iliac fossa; and in all the cases the onset of the disease was as had been described by the author of the paper—pain, shock, and subsequent peritonitis, which became localized within twenty-four hours, and on the third day more or less of the characteristic tumefaction could be made out. In none of those cases would he have been warranted in interfering by operative procedure at an earlier date than that on which the operation was finally performed, and yet all the patients recovered. He believed that at present it was impossible to say positively whether or not the appendix had been perforated, except by autopsy or by the formation of adhesions. He thought that the question was immensely difficult to answer when asked with reference to a prophylactic operation.

Dr. Weber then referred to a case that had lately been under his care, and which possessed points especially interesting. A gentleman, aged fifty-three years, who had enjoyed an average degree of health, came to him with intermittent fever, from which he finally recovered. A few days subsequently, on a Wednesday, he came, saying that he had a pain in the right side of his bowels. There was no fever, and the pain was not severe. A cathartic guarded with opium was administered. On Thursday morning Dr. Weber found that his patient had passed through the period of shock attending perforation and into peritonitis. His abdomen was universally tender, particularly in the right iliac region; he was vomiting, had had no stool, and the doctor thought he would die within a few hours of general peritonitis. But he did not; and under the free use of morphine hypodermically, and stimulants, he rallied, and at the end of forty-eight hours was out of immediate danger. No tumor developed anywhere. Four days afterward the bowels moved spontaneously, and the patient was doing well. On the fifth day the bowels began to move at 6 A.M., and discharged ten or twelve times spontaneously; the abdomen became rigid, the pain increased, and death occurred from general peritonitis that night. He reported the case for the purpose of directing attention to the importance of not discontinuing the opium too soon, especially in elderly patients where there is diminished tendency to plastic exudation; and repeated action from the bowels should be prevented.

Dr. R. F. Weir said that he had been interested in the paper, because it helped to confirm an idea that had been floating in his mind for ten years. He believed that where the diagnosis could be clearly made out, and he could easily understand that it would be difficult, perhaps a long time would elapse before he could feel sure and before he would advise the performance of the operation; but when sure of the diagnosis, he would advise the operation, as it gave a chance of saving a human life. He thought he would go a little further than Dr. Burchard had done, and would say that the patient would have a little better chance of recovery if the operation should be performed, even after peritonitis has developed. He also joined with Dr. Weber in the statement that the conclusions presented by the author at the close of his paper were not apposite in this connection, because there was more than intestinal obstruction, namely, a foreign material in the peritoneal cavity.

Dr. Quackenbos referred to a case in which the patient died within twenty-four hours after she was seized with the intense pain. There was a difference of opinion concerning diagnosis, but Dr. Alonzo Clark's was verified at autopsy, when a perforation of the appendix vermiformis was found. Lodged in the opening was an apple-seed and a piece of the husk of the core.

Dr. Wm. T. White referred to a case in which there was found at autopsy an abscess projecting forward from the anterior wall of the appendix, about the size of a small hickory-nut. There were no adhesions. There was no evidence of peritonitis. The abscess had ruptured, and caused the death of the patient within a few hours.

Dr. J. C. Peters had seen several cases, all of which had been preceded by repeated attacks of pain in the region of the cæcum. He also referred to the fact that Dr. Jacobi had called attention to the occurrence of such attacks prior to the perforation of the appendix.

Dr. A. C. Post was inclined to think that some hope might be afforded in some of these cases by performing an operation, as suggested by Dr. Burchard, and he agreed with Dr. Weir in the opinion that peritonitis was not a reason, necessarily, why it should not be performed.

The President remarked that Mr. Spencer Wells had proved that peritonitis was an indication for the immediate performance of ovariotomy to prevent it from being fatal. He thought that opinion was generally accepted by ovariotomists where the peritonitis was due to the ovarian cyst.

Dr. Burrall suggested the constant wearing of a flannel bandage about the abdomen in cases of repeated typhlitis, as a prophylactic against the attack, which might require operative procedure.

Dr. Chadsey favored the proposed operation, and **Dr. Sell** spoke of the difficulties in diagnosis.

Dr. Burchard, in closing the discussion, admitted the difficulties in diagnosis, but believed that occasional cases occurred in which the history of the patient was well-known to the physician—a history of repeated attacks of typhlitis—and in that class of cases he believed the surgeon was justifiable in cutting down at once after the patient had rallied from the collapse, and establishing free external drainage.

The Academy then adjourned.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Adjourned Stated Meeting, November 29, 1880.

Dr. A. E. M. Purdy, President, in the Chair.

Dr. David Webster read a paper on

AMBLYOPIA FROM THE ABUSE OF TOBACCO AND ALCOHOL (SEE P. 649).

The paper being before the society for discussion, **Dr. D. B. St. John Roosa** remarked that the task of proving the causes of diseases was a difficult one. It was, in a general way, well settled what the cause of intermittent fever was, but the exact nature of malaria was far from being definitely known. So, also, the cause of certain lesions occurring in syphilis was generally recognized; but when we came to speak of the abuse of tobacco as a cause of disease we were upon much more unsettled ground than that occupied with reference to either syphilis or malarial fever. The abuse of tobacco, if the cause of amblyopia, was not a universal cause. Take, for example, the Turks, who smoked from morning until night, and during the night, and, so far as statistics went, tobacco amblyopia was almost, if not quite, unknown among them. Again, all about us there were men who smoked from the time of getting up until the time of going to bed, and yet had no occasion to consult oculists on account of disturbed vision. In the light of those facts we were amid difficulties, and when they were coupled with the observations made by Dr. Ely, who did not find tobacco amblyopia among constant workers in the weed, the difficulties surrounding the question were greatly increased. But it should not be said, on account of those difficulties, that tobacco amblyopia did not exist; yet, he thought that other things were at work, in conjunction with tobacco, in causing these peculiar eye-symptoms. Nevertheless, he believed as firmly as did Dr. Webster that amblyopia was caused by tobacco and alcohol combined, but he thought that it remained unproven that amblyopia had been caused by *tobacco alone*. The author of the paper had referred to Dr. Jonathan Hutchinson's views and statistics, and had quoted his words as those which went far toward settling the difficult question; but, Dr. Hutchinson had been wrong in some of his statistics upon other subjects, and Dr. Roosa thought that his observations were also incorrect in this particular. Dr. Roosa thought that Dr. Webster's cases did not sustain the belief that amblyopia was produced by tobacco alone. He did not believe that amblyopia was caused by tobacco, unaided by alcohol. He would not say that he disbelieved it; but, as yet he was not prepared to accept the belief that it did. As an illustration, a man with naso-pharyngeal catarrh and thickened mucous membrane of the middle ear, was very liable to break one of his drumheads while bathing in the surf; while he who had a moderately sound pharynx took only a very small chance of having his drum-heads ruptured during sea-bathing. So, he thought, it was concerning tobacco and alcohol amaurosis. When the histories of that small percentage of all eye cases, less than $\frac{1}{100}$ per cent., were read, it would be found that most of them had lived lives which would not guarantee immunity from disease in many ways.

There was one interesting feature in Dr. Webster's statistics, namely, they did not include the cases of any clergymen. Dr. Roosa had seen three clergymen who had, as he believed, amblyopia depending upon the abuse of alcohol and tobacco.

With reference to Dr. Webster's conclusion, that amblyopia from tobacco and alcohol was not uncommon, he would say that, while he would not disagree, perhaps, strenuously with it, he did not think the cases were of very frequent occurrence.

Again, whatever might be said with reference to etiology, his personal experience inclined him to support Dr. Webster in his opinion concerning the efficacy of strychnia in this treatment of the affection. He would not dare to withhold the strychnia in such cases.

The incipient atrophy of which the author of the paper had spoken, Dr. Roosa had not seen in any great proportion of cases. He had more frequently seen dirty white disks than smallness of the vessels. In some cases ophthalmoscopic examinations had told him, literally, nothing, and yet the patients improved promptly upon abstaining from the use of tobacco and alcohol, sometimes alone and sometimes in conjunction with strychnia.

While such a question could not be settled at once by observations made by any one man, or any set of men, the subject was greatly illuminated by such contributions as that with which the Society had been favored, and he believed all would agree that, to certain persons living under certain conditions, alcohol and tobacco might become so poisonous as to produce in them failure of vision, which was remedied in a large proportion of cases by correcting their habits, and by the use of such remedial agents as strychnia.

Dr. H. Knapp believed that tobacco and alcohol amaurosis was by no means rare. It constituted a considerable percentage of his private practice, and to a certain extent was seen in his hospital practice. The remark that some were affected unfavorably by alcohol and tobacco, but that the majority were not, could be applied to all causes of disease. Again, it must be recollected that there was not only a difference in the tolerance among different persons, but that the tolerance manifested by any one person while young might not be sustained through life.

Like the pitcher that goes to the well, it gets broken at last.

With regard to diagnosis, persons came complaining of impairment of vision; they were examined and, as was usually the case, central vision was rather low, and ophthalmoscopic examination did not reveal any change adequate to account for the impairment of sight. That was in the beginning of the case. But when the case was an advanced one, a proportionate change was found in the optic disk, and still later the arteries and veins might become so much reduced, both in size and number, that the disk resembled the highest degrees of atrophy.

But returning to the class of cases in which there was no adequate changes in the disk to explain the impairment of vision. In those cases, Dr. Knapp believed there was something characteristic in the functional disturbance itself. The periphery of the field of vision in those patients was normal, and colors could be distinguished quite well, but not so in the central portions of the visual field. In the central portions of the visual field there is achromatopsia, and sometimes it required examination with small pieces of colored paper, or similar objects, to detect it; and, from that degree, the defect might be increased until they become totally color-blind. Therefore, when he saw a patient whose central visual field was very low and peripheral visual field good, and whose central perception of colors was wanting, and the peripheral perception of colors normal, and there was no change in the fundus, he gave a good prognosis, as a rule, because radical improvement was usually obtained. He had seen exceedingly rapid improvement take place in such cases without the use of remedies, and a case in point was related. When we had to deal with reasonable people, and gave them no remedy other than perhaps iron, and bromide of ammonium or potassium at bedtime, good results were generally obtained; and the first improvement was manifested in color perception, beginning with yellow and blue, and, within a few weeks, all scotoma has disappeared.

He believed that such cases were not isolated, but were as common as glaucoma, and it was an important disease for the general practitioner to become acquainted with and to treat. The cases of rapid improvement from strychnia had seemed to him to be more or less isolated.

Dr. O. D. Pomeroy regarded the extremely rapid improvement under the use of strychnia, mentioned by Dr. Webster, as exceedingly interesting, and such as exceeded the experience of any other observer in this country. However, he had seen good results follow the use of strychnia, and he should continue its use, because of those good results, although there were many difficulties encountered in determining whether or not the strychnia cured the patient. He thought it was very difficult to determine the exact cause of the disease in this class of cases. Many persons had amblyopic symptoms, and when their eyes were examined with the ophthalmoscope the conditions found did not really prove anything—the outer portion of the disk being a little white, the inner portion a trifle reddish, and the border a little inexact, etc. In seeking for a cause the examiner was very apt to fasten upon some disease of which there might be only obscure evidence, such as syphilis, kidney, cerebral, or cardiac disease; but it was well-known that the number of the cases was great in which no adequate cause for the trouble could be found. The etiology of the affection under consideration was difficult to determine. Tobacco and alcohol seemed to be so intermingled that it was with great difficulty they could be separated. His own belief was that tobacco had but little influence in producing amblyopic symptoms, while at the same time he felt quite sure that alcohol exerted a marked influence in the production of those symptoms. For, abstaining from alcohol alone would cause improvement, while abstaining from tobacco alone had little or no effect. But there was another element to be taken into consideration, and that was visual intelligence. The amount of a patient's vision, when tested for the first time, depended largely upon his visual intelligence. A stupid patient might read $\frac{20}{30}$, while an artist, with the same actual condition of the eyes, would probably read $\frac{20}{18}$. Again the cultivation of the visual intelligence was another factor in the case; for a constant improvement took place by simply testing the patient; that is, he could see better with the same eyes at the close than at the beginning of the exercise. There was also another factor which must be considered, and that was the improvement that might result from the lapse of time. However, he was in favor of being upon the side of the positivists rather than among the negativists, and should continue to inject strychnia, hoping to improve the vision of his patient.

Dr. W. B. Mittendorf remarked that he used strychnia in these cases quite extensively for four or five years, and nearly every time the patients were made worse instead of better, thus proving that abstinence, perhaps, was a more important factor than the strychnia in effecting a cure. All his patients were below par in their general condition, and he had thought that, as soon as the system gets reduced, tobacco and alcohol would produce their ill effects; for so soon as they were tolerably well they returned to their old habits with apparent impunity. He regarded strychnia, however, as a valuable remedy, yet care should be exercised in its administration. He then referred to a case in which $\frac{1}{60}$ of a grain, given to a man thirty years of age, produced such marked symptoms of poisoning that he was afraid to repeat the remedy.

Dr. C. R. Agnew said that he placed his cases at Dr. Webster's disposal, knowing, as all who knew him did, how accurate and conscientious he was in all his observations, and how capable he was of making adequate and logical deductions. He also said that he had been somewhat surprised at the tendency which he thought had been manifested to wander from the facts in the paper. The gentleman knew quite as well as he did that statistics, if there be such to any very great extent, with regard to the effect of tobacco upon the people of the Eastern nations, especially the Turks, were not such as we would be quite willing to adduce here in support of the innocuous character of tobacco. He thought there were not many observers in the East whose judgment in this matter we would be willing to accept in New York, where, it might safely be said, the results of careful general ophthalmoscopic observation had been carried to a niceness and accuracy that certainly did not exist in the East, if it existed anywhere abroad. This subject, like many others, had been subjected to great scrutiny, and probably there was a greater aggregation of careful observers in this city than could be found in any single place in the world. He for one was not disposed to accept Oriental statistics, as he knew them, as really having much bearing upon the subject. He was free to say, and in that he agreed with the gentleman to whom he alluded, that amaurosis from tobacco alone, without the possible occurrence of syphilis and the possible abuse of alcohol, was comparatively rare. But, on the other hand, there existed curious facts, which made it safe in drawing the logical conclusion that there was a pathogenetic relationship between alcohol and tobacco, hence they were united in the discussion of that particular form of disease. He thought that the ground would be much more securely occupied if, in treating a series of cases hereafter, we should insist upon abstinence from tobacco alone and alcohol alone, and observe the clinical phenomena. One of the gentlemen had confessed his scepticism as to the effect of remedies. But it could not be denied that abstinence from the use of tobacco and alcohol, in some of the cases reported, had enabled the patient to spring up in the use of his nerve-power and show improvement so rapidly as to exclude the influence of the mind upon vision, which the gentleman would lead us to infer had been exerted. Again, that element did not enter, because the observations were made in his office, where they had two tables of test-type, one differing entirely from the other, for the purpose of excluding that possible source of error. If a patient read $\frac{20}{100}$ on the first day, and several days afterward, with the same illumination, and either under the effect of abstinence or under the influence of a remedy, he read $\frac{20}{70}$, and it was repeated a sufficient number of times, the inference was that his mentality of vision had not been so cultivated as to enable him to read a line of letters which on the first day he could not see.

Dr. Agnew believed that all proper precautions had been taken in making the observations. The urine had been examined by Dr. Maxwell, whose ability was fully recognized, and the physical examinations of the chest had been made by Dr. Leaming, or Dr. Clark, or Dr. Flint.

In order to determine the frequency of such cases, they must not be compared with the total number of cases of ophthalmic disease. It was obviously proper, in getting the relative frequency, to exclude large classes of cases. Children should be excluded, and blindness from such causes as cataract, detachment of the retina, conjunctival affections, etc. If the cases were selected in which the dioptric apparatus was not affected, but those in which the lesions were in the perceptive apparatus, he thought it would be found that the number of cases was relatively large, although it might be absolutely small. He could not recall many cases in which tobacco was the sole cause of the amblyopia, but had had a few. He believed that the relationship between the two poisons—tobacco and alcohol—was such that they were indissolubly united in some persons, and that we should seldom succeed in breaking them from one habit unless they were broken from the other. We should make issue with the patient, and insist that he abstains *totally and at once* from the use of both tobacco and alcohol. Then, after waiting a reasonable time—a week or ten days—use the strychnia if necessary. He had waited the time indicated and seen little or no improvement, and had then seen the vision of several patients doubled in strength while in his office and after receiving an injection of strychnia. He felt personally indebted to Dr. Webster for gathering the facts presented, and he regarded them as indisputable.

Dr. Knapp remarked, concerning the injurious effects produced by either tobacco or alcohol alone, that alcohol was more injurious than tobacco. He had seen a few cases of toxic amaurosis in patients who had the opium habit.

Dr. Roosa remarked that Oriental statistics had been subjected to a criticism with which he did not agree. The point which he wished to make was, that tobacco amblyopia was rare. He did not believe in it; he did not disbelieve in it; and he adduced as some of the reasons for his non-belief, Dr. Ely's observations, which were sufficiently accurate to endure any criticism, and statistics furnished by a gentleman in Constantinople, and published in Dr. Brudenell Carter's text-book on diseases of the eye. True, they were not such statistics as Dr. Webster had furnished, but they were those of a physician who said, in general terms, that amblyopia seemed to be unknown among the Turks, and he had made his observations as a medical man. From those statistics and from general observations, Dr. Roosa thought that *tobacco* amaurosis was not particularly common, and he did not regard the statistics adduced by the author of the paper as pertinent to the subject of the influence which tobacco *alone* had in producing amblyopia.

Dr. Agnew remarked, that he would not discard Dr. Ely's statistics by any means; but he believed that in the discussion of this particular subject we must exclude the evidence of physicians who had not subjected the vision to the test of its acuity, and had not given us positive statements with reference to the amount of vision the patient had, and the effect of remedies in changing the amount of that vision. As to the effect of trades upon the health, it was well known how broad the subject was, and how soon the observer got to sea when he entered that field of observation. He thought that Dr. Ely's statistics could be justly applied to the question under discussion.

Dr. Webster remarked that the *rapid* improvement of vision under the influence of strychnia occurred in cases of amblyopia from alcohol and tobacco. But he had seen vision considerably improved by its use in cases of atrophy of the optic nerve from other causes. Yet, after a time, vision had failed in the latter cases despite the use of strychnia. In the amblyopic cases the rapid improvement was permanent.

On motion by Dr. Mittendorf, a vote of thanks was extended to Dr. Webster for his admirable paper.

Dr. J. C. Peters made a preliminary report from the committee appointed to confer with a similar committee from the College of Pharmacy with reference to a city ordinance regulating the sale of poisons, poisonous drugs, etc. The joint committee had recommended that the Board of Aldermen adhere to the ordinance already before them.

STREET-CLEANING AND REMOVAL OF NOXIOUS ODORS.

Dr. Peters also offered resolutions, which were adopted.

Resolved, That many members of this Society, have noticed, with regret, the dilapidated and filthy condition of the majority of the streets and avenues of this city, and their gutters, especially on the East and North rivers, and in the great plague districts from whence all great epidemics either originate or are greatly intensified; but to which paving materials are most easily conveyed, and from which the great masses of filth which encumber them are most readily removed.

Resolved, That many members of this Society, probably the great majority, are fully convinced that this state of things is the sole cause of much sickness and mortality.

Resolved, That in the opinion of the great majority of the members of this Society, the large quantity of street or gutter filth, slops and garbage which is carried down into our sewers, causes much increase of the quantity and malignity of the sewer gases, followed by a still greater sickness and mortality.

Resolved, That a moderate appropriation for the better paving of some of the worst conditioned streets, notably the Eleventh and part of the Tenth avenue, and for improving the condition of the sewers, will not only be timely, but absolutely necessary, to prevent New York from becoming a permanently unhealthy city, with great sickness always abounding, and great plagues and pestilences often appearing.

Resolved, That this Society will petition all persons in authority to aid it and its Committee on Hygiene to place this city in a better sanitary condition.

Resolved, That in the presence of probable great epidemics of diphtheria and small-pox, and of others which will surely come at no great distance of time, that the Board of Aldermen should now, if ever, become the watchful guardians of the public health, and enforce all those ordinances which they have so wisely passed, also create new ones if necessary; and that it should be pleased to instruct its Corporation Counsel and all its law officers to watch for, detect, and condignly punish all offenders against its own laws and ordinances.

Resolved, That the Police Board be requested to instruct its officers and patrolmen to faithfully observe and report all breaches of the laws against the defilement of the streets and gutters; and that its attorneys and law-officers prosecute all offenders rigorously.

Resolved, That the Street Cleaning Bureau be requested to strain every effort with its present appropriations and appliances to remove all the street dirt, ashes, garbage, etc., from the city at once, and constantly; also, if stress of weather prevent it from carrying these loathsome but useful fertilizers down to sea, that it makes the best arrangements possible with parties along the Harlem and Hudson River and other railroads, and with persons in New Jersey, Long Island, and other neighboring places, who will be glad to get them for fertilizers and filling materials.

Resolved, That the legal counsel of the Street Cleaning Bureau be requested to exert its utmost diligence and ingenuity in drawing up contracts with these parties of equal force, at least, and completeness, with those which ordinary business men make daily.

Resolved, That the Department of Public Works be requested to defend its sewers and docks from all injury which may arise from defective street cleaning, and to employ legal counsel necessary for this purpose.

Resolved, That the Board of Health, which is especially constituted to protect the health of the city at all hazards against all corporate and private interests, be requested to use all its powers to have our streets and gutters better cleaned; our sewers better protected and amended; that it increase its corps of Sanitary Inspectors in order that all nuisances may be better detected and obviated; and that it take immediate steps to remove all noxious trades, shanty districts, and plague spots, which cannot or will not be controlled by sanitary science.

Resolved, That the great slaughtering and plague districts on the east and west sides and centre of the city be put in the best sanitary condition that the Boards of Works and Health can devise; that the streets and docks in their neighborhood be repaired and cleaned; that the manure and garbage dumps near the great slaughtering districts be promptly removed; and that all the offal-rendering establishments be ordered away, as far as possible, from the places where the principal parts of the meats are killed, especially on the east side of the city; for freshly killed meat requires the purest air all around it.

Resolved, That all these petitions and resolutions be presented to the Honorable Board of Aldermen with a respectful but most earnest request for all its aid and best advice in these matters, and subsequently the special points which refer to particular departments be placed before them also.

[The above resolutions have been referred to the Committee on Law of the Common Council.]

The Society then adjourned.

Correspondence.

AMBLYOPIA FROM THE ABUSE OF TOBACCO.

To the Editor of The Medical Record.

Sir—In the discussion on Dr. Webster's paper at the last meeting of the County Society, I alluded to the alleged absence of the so-called "Tobacco Amaurosis or Amblyopia" in Turkey. I was speaking extemporaneously, and I was not able to say whether the opinion that there was little amaurosis in the East, was founded on the observations of a general practitioner or on that of a specialist. It was thought by one speaker that the opinion was not entirely pertinent to the discussion, because it was not founded on exact observations like those of Dr. Webster's. On looking up the subject in the work from which I was quoting, that of Mr. Carter,* I find the opinion better substantiated than was supposed. I beg, therefore, that you will print the quotation in connection with your report of the discussion in question. Mr. Carter says "I quoted a letter from Dr. Dickson, of Constantinople, . . to the effect that the consumption of tobacco in that city averaged about three pounds weight per head per month for the whole population, but that amaurosis was a rare affection there; and also a letter from Dr. Habsch, the principal oculist in Constantinople." (I now translate the statement of Dr. H., who wrote in French.) "As to the effect of tobacco upon the eyes, it is very problematical. All the world here smoke, from morning until night, the men smoke a great deal, the women a little less than the men, and children smoke from the age of seven to eight years. I have never attributed amaurosis to the use of tobacco. The number of smokers is immense, the number of cases of amaurosis is limited. In persons with a very delicate skin and conjunctiva, smoking freely causes chronic irritations, local congestion, blepharitis ciliaris, continuous lachrymation, and a more or less intense redness" (of the eyelids). "So much for the effect of tobacco."

I am, sir, yours respectfully,
D. B. St. John Roosa.

December 1, 1880.

CLINICAL ADVANTAGES IN PHILADELPHIA.

To the Editor of The Medical Record.

In your issue of November 4th there is what purports to be an extract from the *London Lancet*, written by a Philadelphia correspondent, reflecting seriously upon the clinical teaching of the Philadelphia hospitals. "Clinical study," says this Cerberus, "in the medical curriculum, is apparently unnecessary. I was assured that at the Jefferson College, which is one of the leading medical schools in the country, a man might take his degree in medicine and go forth to practise his profession without ever having seen a case."

Who this slanderer is I, of course, do not know, but I am deeply chagrined to see such a paragraph in your widely-circulated journal without a flat contradiction. Instead of this, you place a part of the last sentence in italics, with a note of exclamation, as much as to ask, "Can this thing be possible?"

This thing is not possible. Everybody acquainted with the history of the Philadelphia schools knows that the statement of the correspondent of the *London Lancet* is false in every particular. Without going into comparisons, it is safe to assert that nowhere on this continent is there greater attention bestowed upon clinical teaching than there is at our hospitals. Elderly men, middle-aged men, and young men, all able, more or less highly cultured and fully up, in point of knowledge, with the existing states of the various branches of the medical sciences, are daily engaged for at least ten out of every twelve months in delivering instruction of this kind in connection with our large and well-equipped hospitals. As to the Jefferson Medical College, into which this slanderer seems to take special delight in fastening his venomous fangs, it is a well-known fact, a fact which long ago passed into history, that it was the first school in this country in which clinical instruction was given. It was emphatically the founder of the surgical clinics of the United States, if not also of the medical. Those who were acquainted with Dr. George McClellan, the founder of the school—a man of great genius and of large reputation as a skilful surgeon and an eloquent lecturer—will have no difficulty in awarding to him this distinguished honor. For at least forty years the college has prided itself upon its clinical teachings in surgery, medicine, and midwifery, to which were recently added gynecology, ophthalmology, otology, and laryngology—in fact, everything that is taught in any of the best schools in the world. Daily clinics are held in the magnificent amphitheatre in the new hospital dedicated three years ago. What is true of the Jefferson College in this respect is equally true of the University of Pennsylvania. Both schools have most able corps of clinical teachers, inferior to none in this or, I venture to assert, in any other country.

The slanderous statement of the London correspondent can only be explained on the supposition that he is the very fellow who, by the grace of God, obtained a degree from the college *without ever having seen a case*, his indolence and indifference not having permitted him to avail himself of the precious pearls that are daily thrown before *such* swine in the ample amphitheatres of the Philadelphia hospitals.

I am, very truly yours,
S. D. Gross.

Philadelphia, December 5, 1880.

[We made the quotation for what it was worth, and on the authority of a correspondent of the *London Lancet*. We preferred that a denial of the facts in the case should come from headquarters, and we publish the letter of Prof. Gross with great satisfaction.—Ed.]

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from November 28, 1880, *to December* 4, 1880.

Majors J. R. Smith and J. S. Billings, Surgeons, directed to represent the Medical Department of the Army at the eighth annual meeting of the American Public Health Association in New Orleans, La., on December 7, 1880, and upon adjournment of the Association to rejoin their proper stations. S. O. 351, A. G. O., November 26, 1880.

Coues, Elliot, Capt. and Asst. Surgeon. Relieved from duty assigned him in S. O. 134, July 3, 1876, from A. G. O., and to report in person to the Commanding officer, Department of Arizona, for assignment to duty. S. O. 251, A. G. O., November 26, 1880.

King, J. H. T., Capt. and Asst. Surgeon. Granted leave of absence for four months. S. O. 253, A. G. O., November 29, 1880.

Medical Items and News.

Contagious Diseases — Weekly Statement. — Comparative statement of cases of contagious diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending December 4, 1880.

A Chair of Physiology is to be established at Oxford University.

Snow-Blindness, according to Dr. Reed, of Detroit, can be cured by the administration of nitrite of ethyl.—*Canadian Journal of Med. Science.*

Investigation of Insane Asylum Methods.—The Senate Committee to inquire into the alleged abuses in the management of insane asylums, and to suggest measures of reformation, if necessary, began its work in this city on November 30th. A very large amount of testimony has been taken already, and at date of writing the investigation was still going on. The testimony began with the presentation by Dr. McBride of a petition to the Legislature, prepared by a Committee of the Neurological Society on Insane Asylum Abuses. This petition presents very forcibly the various points that have been so often made against the present system of asylum management. The testimony of the different witnesses against present methods, was for the most part an elaboration of the various indictments made in the petition. Some of the statistics given, however, and particular facts testified to, were of much interest.

The proportion of assistant physicians to patients in 1878 was as follows:

At the Utica Asylum, 4 assistants to 600 patients; at the Hudson River State Hospital, 2 assistants to 250 patients; at the Willard Asylum, 5 assistants to 1,340 patients; at the City Lunatic Asylum for Females, Blackwell's Island, 7 assistants to 1,267 patients; at the Institution for Males on the same Island, 5 assistants to 1,084 patients; at the Kings County Asylum, Flatbush, 4 assistants to 700 patients, the proportion of assistants to patients varying from 1 to 268 in the female asylum on Blackwell's Island to 1 to 125 in the Hudson River Hospital.

As illustrating the evil that may result from the insufficient number or incompetent character of attendants, the burning of the insane asylum at St. Paul, Minn., was instanced. Here a lunatic was allowed by his keeper free access to the kerosene.

Regarding the benefits of employment, Dr. Hammond testified that at the Poughkeepsie Asylum Dr. Cleveland was in the habit of turning out patients, with strong homicidal tendencies, with pickaxes and other formidable implements in their hands, and this without any evil results.

Regarding insufficient salaries, Mrs. J. S. Lowell stated that the salaries of the superintendents of our city asylums were from $2,000 to $2,400, while the superintendents of asylums through the State received from $3,500 to $4,000. Both the present superintendents of Ward's and Blackwell's Islands were good men, but it was a wonder that they were under such a system. Of the assistant physicians only a few received salaries. There were two who received $500 each, three who were paid $300, and one who received $250. As a rule, the assistants received only their board. As to the nurses, she thought there should be a higher grade established, with better pay, to which competent nurses could be promoted. With this additional grade and increased numbers, she thought the present pay of $18 to $20 per month sufficient. The great faults of attendants were ignorance and want of judgment.

Regarding the scientific work done at insane asylums, it was stated that $30,000 had been expended in the Utica Asylum for scientific investigations, with very inadequate and unscientific results, which results had been adversely criticised by distinguished foreign authorities.

As to overcrowding it was testified that of the 1,200 insane males on Ward's and Blackwell's Islands, there was not room for more than 500. Of the 3,029 insane belonging to the city, there was not accommodation for more than 2,000 at the outside in the present institutions. There was not room on the islands for more hospitals. The number of insane under medical control had increased 100 per cent. in nine years, and the State had paid $10,000,000 in the last decade for new asylums. With this large number of insane patients on their hands, the Commissioners of Charities had also to care for 7,000 other persons, and the 3,000 lunatics were left with no one but the superintendents to care for them. It was thought that, in view of the large sums contributed by New York to the erection of new hospitals in the interior, the State might well be called upon to pay the salaries of the medical superintendents and staffs of these local institutions.

As to political influence, Dr. L. C. Gray testified that in Kings County there existed (with a few honorable exceptions) the worst and most unscrupulous of Commissioners. The method of appointments by Commissioners was bad. Under the present system anybody could be appointed to take charge of 800 to 900 patients, without anything like adequate knowledge of insanity, which was one of the worst, most complicated, and difficult to treat of all diseases.

For evidence on the other side, Dr. A. E. MacDonald, Dr. Franklin, the charity commissioners, and others, principally asylum employees, were called in. Dr. MacDonald denied that excessive restraint was employed in the Ward's Island Asylum. Most of the other facts given by previous witnesses, regarding the management of the city asylums, were confirmed, but the witness thought that the superintendents did all that was possible under the circumstances. Dr. Franklin agreed with Dr. MacDonald for the most part. He defended the use of the crib.

THE FUNERAL OF HEBRA was an event to be remembered in Vienna. A procession one mile and a half in length followed the remains to their resting-place. A great multitude rendered the streets almost impassable. Eager to do him homage, laymen, students, scientists, and nobles, all commingled, paid by their presence that silent tribute which is more eloquent than words. He lies buried by the side of the great Rokitansky.

The successor of Hebra is Professor Kaposi, who is well known to the profession by his various contributions to the literature of dermatology. A person of quick, nervous temperament, he combines a vast knowledge of his subject with the qualities of a brilliant lecturer and a good teacher. His class numbers more than that of any other teacher in his department.—*Cor. Cincinnati Lancet and Clinic.*

THE TREATMENT OF ACNE ROSACEA, or "whiskey-nose," by electrolysis, is advocated by Dr. G. S. Mitchell *(Cincinnati Lancet and Clinic)*. He reports seven cases cured, or almost so, by this method. He uses fifteen or twenty cells (galvano-faradic cabinet battery). One or both poles of the battery are armed with needle-electrodes, and these are introduced here and there into the dilated vessels. The needles are not allowed to remain more than half a minute in one place, the treatment lasting about five minutes. From eight to twelve seances were sufficient to cure the patients. The operation is painful, though not so much so as to require an anesthetic.

MEDICAL PRACTICE IN AUSTRALIA.—A correspondent of the *British Medical Journal* deplores the state of medical affairs in Sydney and the adjoining places. The greatest difficulty, he says, which meets attempts at reform, is the great sympathy shown for unqualified practitioners by the people and even legislators. Many think that these latter are better and more honest men than the regularly qualified physicians. Sydney and the other larger towns of the colony are well provided with good practitioners of high standing; yet in spite of this, many people rush off to any one calling himself a homœopath, whether duly qualified or not. Impudence and advertisement, especially if combined with the word homœopath, seem to ensure success invariably. They all advertise, and generally some specialty, such as cancer-cure, etc. There are some Chinamen in the colonies who call themselves doctors. One of these, at Sydney, is a "Dr. On Lee," and many people run after him who ought to have more sense. He finds out as best he can beforehand, what other doctors think about his patient, and then takes up a glass, which he holds before his patient: then with the greatest confidence, he tells the patient that he has seen in the body the very spot affected, and finally gives the patient a small diagram showing the exact spot.

Efforts to pass a law in Parliament remedying these abuses have so far failed. Australia and New Zealand seem to very well supplied with doctors. There is a superfluity, indeed, in the cities. The country practices are hard and not very lucrative. Still there are many places where a good living can be obtained by perseverance and work.

The Telephone as a Cause of Aural and Nervous Diseases.—A reporter of the *New York World* has been interviewing eminent specialists in nervous and aural diseases as to the effect which the use of the telephone has upon the human organism. One specialist reported that he had then a telephone operator under treatment for certain nervous disturbances which he thought might have been brought on by the instrument upon which the patient was employed. Another said that, as every new invention produced a new disease, something might be expected from the telephone, though it was as yet too soon to say what the particular trouble would be. On the whole, pathologists may look hopefully to the telephone for the production eventually of some new phenomena.

Epizoötic in Ottawa.—Seventy-five per cent. of the horses in the Ottawa district are affected with the epizoötic.

A Death from Hydrophobia has been reported in Washington. The patient was a boy, aged eight years, who was bitten in the cheek four weeks ago by a hound.

Small-Pox.—Ten cases of small-pox were reported in this city last week. Twenty patients are now in the Small-pox Hospital, Blackwell's Island.

The American Public Health Association commenced its eighth annual meeting in New Orleans, December 7th. About one hundred members were present.

A Death from Trichinosis occurred on Saturday last, at Bellevue Hospital. The patient was a young butcher who had been in the habit of eating raw pork.

Cod-liver Oil in Epilepsy.—Dr. Fairbairn, of Brooklyn, N. Y., writes: The digestive disorder and annoying and disfiguring eruption which result from taking the bromides in large doses for a length of time, are serious disadvantages connected with the administration of these salts. A remedy which will prevent the bad effects of a medicine, and at the same time will rather aid than detract from its good effects is certainly a valuable one. I think in this case we have such a remedy in cod-liver oil.

A young lady suffering from epilepsy has been under my care for the past five months, who has taken bromide of potassium in large doses for nearly a year, and by this remedy cod-liver oil has warded off the above troublesome results. The mode of taking it was this: Brom. potas., ʒ ss., was taken thrice daily after eating; this was followed one hour after each dose by ol. morrhuæ, ℥ ss. When first attacked by the malady she had eight convulsions in the twenty-four hours. She began the bromide in ʒ ss. doses, but was compelled to stop it on account of the gastric derangement. A friend recommended the cod-liver oil. She resumed the bromide, adding the oil, and has taken it without further trouble since. The eruption, before profuse, disappeared under this management. The disease has been well controlled, only four convulsions having occurred in the past seven months. I doubt not that the cod-liver oil has had its share in the direct benefit done to the nervous system, besides affording a protection from the irritating salt to the coats of the stomach. In summing up the good effects of the oil I find: *First.*—Absence of the digestive disorders. *Second.*—Absence of the acne eruption. *Third.*—That the anæmia, usually found in persons taking this medicine continually, is far from being marked. *Fourth.*—The body is better nourished, and appetite unimpaired. I have made trial of this treatment in other cases, with similar good results. As the articles that have appeared in your journal, in the past month, on the bromides, have made no mention of this device, I have been led to write the above.

Contagious Diseases in 1879 and 1880.—The Bureau of Vital Statistics furnishes the following statistics of mortality in this city from contagious diseases for the nine months ending Sept. 30th, compared with the corresponding period last year. Small-pox, 6 deaths; 1879, 25; scarlet fever, 279; 1879, 1,370; diphtheria, 737; 1879, 453; measles, 468; 1879, 126; croup, 527; 1879, 295; whooping-cough, 219; 1879, 469; typhus fever, 1; 1879, 3; typhoid fever, 109; 1879, 126; malarial fever, 339; 1879, 299; cerebro-spinal meningitis, 133; 1879, 84.

From the above it will be seen that there has been an increase during the present year in diphtheria, measles, croup, malarial fever and cerebro-spinal meningitis. In all but malarial fever the increase is about double.

There was a decrease in small-pox, scarlet fever, whooping-cough, typhus, and typhoid fevers.

The Medical Profession and the Homœopaths.—Numerous instances of consultations between homœopaths and regular physicians occurred in Dublin not long ago. The practice, indeed, had existed for some time. But finally it became so glaring that the Royal College of Surgeons took up the matter.

After some discussion they passed resolutions condemning the practice of consulting with homœopaths and denouncing homœopathy as a deception not to be tolerated among physicians and surgeons who have a regard for their professional character. This resolution was confirmed by the council of the college, and raised quite a storm among the homœopathists who, of course, denounced this action of the regular profession as narrow, bigoted, and cowardly. The resolutions of the Royal College were reasserted, however, and have been sustained by the feeling of the profession.

The *Medical Press and Circular*, in some very forcible comments upon the matter, says words that are worth repeating: The profession distinctly refuses association with homœopaths, because it believes the tenets of that schism—and more especially infinitesimalism—are not doctrines which may be honestly held by reasonable, thinking, and educated gentlemen, but are, on the contrary, theories put forward to attract the uninitiated and impressible section of the public. Of the doctrine of "*Similia similibus curantur*" we do not speak now, for, although with some knowledge of what has been written in its favor, we believe it to be unscientific, delusive, and erroneous, we can still conceive a practitioner honestly holding it and acting upon it. But with regard to infinitesimalism we cannot use any other phrase than to characterize it as a fraud to which no practitioner worthy of professional association should descend. We know, as a matter of fact, that very many homœopaths do not practise on such principle . . . . ; and with every desire to take the broadest and most charitable view of the erratic ideas of individual practitioners, we really cannot coerce our intelligence to believe that homœopaths have any more real confidence in the doxology advocated in the homœopathic Koran than we have.

Death from Blood-Poisoning.—Dr. Thomas Wood, a prominent surgeon of Cincinnati, died November 21st from the effects of blood-poisoning, caused by attending with chapped hands to the wounded in the recent railroad accident on the Cincinnati, Hamilton and Dayton Railroad.

The Adulteration of Food.—The prize of $1,000, offered by the National Board of Trade for "the best act or acts, accompanied by an essay, designed to prevent injurious adulteration, and to regulate the sale of food without imposing unnecessary burdens upon commerce," has just been awarded to Vernon M. Davis, of this city, and William H. Newell, M.D., of Jersey City Heights. The committee also recommend the printing of the essays of O. W. Wight, M.D., of Milwaukee, Wis., and Albert B. Prescott, of Ann Arbor, Mich. The report declares that none of our staple articles of food or drink are so commonly adulterated as to be dangerous to health or life, and that there is much more danger in this country from adulterated drugs than from adulterated food. Both state and national laws upon this subject are desirable.

The International Medical Congress.—At a recent meeting of the Executive Committee of this Congress, it was announced that considerable progress in the arrangements for the coming meeting had been made. Circulars in different languages have been sent to medical men throughout the world. Many and eminent members of the profession everywhere have expressed their interest in the Congress and have promised to be present.

At the Annual Meeting of the Virginia Medical Society held at Danville, October 19th to 22d, Dr. Hunter McGuire was elected President for the ensuing year; Dr. Landon B. Edwards, of Richmond, was re-elected Recording Secretary, and Dr. M. M. Walker, of Richmond, Corresponding Secretary. The next annual meeting is to be held at Warrenton, the date to be settled by the Executive Committee.

The Troubles of a Private "Provident Dispensary."—A kind of woman's private provident dispensary, where the poor could get treated for twenty-five cents, was started in this city last year by two irregular female physicians. About two months ago a disagreement began and the ladies separated, one of the partners occupying the first floor, the other the second. The former woman exercising what she considered her rights as the tenant of the lower floor of the house, had a number of large blue signs painted, and covered the front of her floor and the door with them, to the exclusion of the sign of the lady of the second floor. The latter remonstrated. Receiving no redress, she had prepared a number of conspicuous signs, bearing her name and the title of her establishment in red and white colors. These she had nailed up wherever she could find an unoccupied space about the door, in the vestibule, and even under the front door-bell. War followed, and the matter was carried to court where by means of counsel the matter has been amicably settled.

Locomotor Ataxia Cured by Nerve-stretching.—Dr. Langenbeck reports a case of tabes dorsalis cured by stretching the two sciatic and crural nerves. The stretching was done at different times, and was performed antiseptically. The ataxic symptoms began to disappear very rapidly.

"The West Still Ahead."—The new medical school, somewhere in Minnesota, which started off with such a firing of guns on account of its adopting a four years' graded course, has not, it is said, a single student.

Who first Described Malarial Puerperal Fever.—Some correspondence has appeared in the *Virginia Medical Monthly* upon the above topic. Dr. Hugh M. Taylor claims that the malarial puerperal fever was first described by Dr. O. F. Manson, twenty-five years ago, in the *Virginia Medical and Surgical Journal*. Regarding this claim Dr. Theophilus Parvin writes: "So far, so well. But were there not heroes before Agamemnon?" He then gives quotations from various old works tending to show that as early as 1775 Dr. Butler wrote upon the disease in question; that in 1824 Dr. Blundell, and in 1828 Dr. Burns did the same thing. Dr. Parvin also states that the malady had long been recognized by old practitioners in the West.

In reply to Dr. Parvin, Dr. Taylor reasserts his claims for Dr. Manson, and analyzes the alleged descriptions of the disease by older writers. On the whole, he makes out a pretty strong case for Dr. Manson. Puerperal malarial fever may have been known and treated before 1855, but Dr. Manson seems to have been the first to describe it distinctly.

Pirogoff, the distinguished Russian surgeon, has recently celebrated the semi-centennial anniversary of his admission to the doctorate. Pirogoff is said to be not only a great surgeon, but an eminent philanthropist.

A Monthly Journal of Otology, Laryngology, etc., is to be published in London shortly.

Arsenic in Tincture and Solution of Perchloride of Iron.—Mr. F. W. Fletcher, V.C.S., having noticed that arsenic was quite frequently present in hydrochloric acid, thought that it might very likely be found in the tincture and solution of the perchloride of iron. On making an analysis of several samples obtained from leading drug-houses his suspicions were confirmed. Arsenic was found in the proportion of from ten to fifteen grains per 100 fluid ounces of liquor.—*The Analyst.*

The Lumleian Lectures will be delivered this year by Dr. Reginald Southey. Subject: "Bright's Disease;" the Croonian Lectures by Dr. Moxon, on the "Influence of the Circulation on the Nervous System;" the Gulstonian Lectures by Dr. Coupland, on "Anæmia."

Books Received.

Medical Heresies Historically Considered. By Gonzalvo C. Smythe, A.M., M.D. Philadelphia: Presley Blakiston. 1880.

Horses' Teeth: A Treatise on their Mode of Development, etc. By W. H. Clarke. New York. 1880.

How a Person Afflicted with Bright's Disease ought to Live. By Joseph F. Edwards, M.D. Philadelphia: Presley Blakiston. 1881.

Construction, Organization, and General Arrangements of Hospitals for the Insane, etc. By Thomas S. Kirkbride, M.D., LL.D. Second edition. Philadelphia: J. B. Lippincott & Co. 1880.

Food for the Invalid, etc. By J. Milner Fothergill, M.D., London, and H. C. Wood, M.D., Phila. New York: Macmillan & Co. 1880.

Original Lectures.

CARTWRIGHT LECTURES,*

ON THE

PHYSIOLOGICAL ANTAGONISM BETWEEN MEDICINES, AND BETWEEN REMEDIES AND DISEASES.

By ROBERTS BARTHOLOW, M.D.,

PROFESSOR OF MATERIA MEDICA AND THERAPEUTICS IN THE JEFFERSON MEDICAL COLLEGE, PHILADELPHIA.

(Special report for The Medical Record.)

Lecture V.

THE ANTAGONISM BETWEEN REMEDIES AND DISEASES.

Mr. President and Gentlemen—One of the aphorisms of Hippocrates was that some diseases are cured by contraries; but he was also wise enough, you will remember, to add that some diseases are cured by similars. Even at the remote period when he lived it was already obvious that no one law or dogma could embrace all the various conditions of disease. The doctrine of antagonisms is necessarily applicable only to physiological pathology (if such an expression may be permitted), and not to structural pathology, unless it is remedial by physiological processes. The limits being thus set to our inquiry, we may proceed to examine into the nature and extent of the antagonisms between remedies and diseases, or between the actions of remedies and the symptoms of diseases.

The first historical example of the treatment of a symptom of a diseased state by its physiological antagonist is

THE TREATMENT OF PARALYSIS BY STRYCHNIA.

As has already been stated, we owe our knowledge of this subject to Magendie, whose researches in regard to it were so thorough that later investigators have been able to add but little to the information gained by his discoveries. This investigation, which was the pioneer in a hitherto untried field, is in striking contrast, as regards the permanence of its results, with the variable and fleeting opinions which usually result from empirical methods. Fouquier was the first to prescribe strychnia in paralysis, in accordance with the views which Magendie had deduced from physiological research, and since then a vast amount of clinical experience has accumulated in regard to this important agent.

Strychnia exalts the reflex function of the spinal cord, and is, therefore, antagonistic to those conditions of disease in which this function is impaired. It also strengthens the action of the heart and increases the arterial tension by its stimulating action on the vaso-motor system, and therefore is physiologically opposed to all effects of disease which are of a contrary nature. Furthermore, it powerfully stimulates the respiratory function (causing death from asphyxia, if given in sufficient doses, by exciting the respiratory muscles to tetanic contraction), and is therefore the antagonist of those symptoms of disease which indicate depression of respiration. When we come to examine how far the deductions of theory are confirmed by clinical experience, we find the most abundant evidence to establish their correctness. Diphtheritic paralysis affords an excellent example of the type of the paralysis to which strychnia is an antagonist. It is chiefly a functional paralysis, and although some structural changes have been detected in the spinal nerve-roots, they are remedial under the changed conditions brought about by the action of the strychnia. It being obvious that the remedy will produce the better results the more it is concerned with sound tissues, it follows also that measures adapted to improve the general nutrition will increase the efficacy of the strychnia.

The so-called reflex paralyses, which are especially benefited by the administration of strychnia, are probably often due to anæmia of the motor centre; and strychnia, as is well known, produces rather a hyperæmic condition of the cord and motor centres generally, while it also stimulates them to greater activity.

The action of strychnia on the heart and the arterial tension is not, I fear, utilized to the extent that it should be in medical practice. The enfeebled state of the heart resulting from degenerative changes in its muscular structure, and the coincident low tension of the vascular system, are conditions antagonized by strychnia; and it is also a very useful remedy in exhausting hemorrhage, which produces weak action of the heart and low arterial tension. In this connection I find that Dr. Fordyce Barker is in the habit of giving tincture of nux vomica in considerable doses for the arrest of *post-partum* hemorrhage, which is a most appropriate agent, because so exactly antagonistic to the conditions present. Modern experience has also demonstrated the utility of strychnia in the treatment of depressed states of the respiratory organs.

SPASM AND THE PARALYZERS.

The relation in which strychnia stands to paralysis is comparable to that of the paralyzing agents to spasm and cramp. Woorara, which is the only remedy which has apparently exerted a curative influence on hydrophobia, destroys the irritability of the end organs of the nerves in the muscles (while leaving the muscles themselves intact), depresses and suspends the reflex function of the spinal cord, and paralyzes respiration. Hydrophobia gives rise to symptoms in opposition to these; but, unfortunately for the efficacy of woorara in its treatment, the drug varies greatly in composition, while in hydrophobia a peculiar virus is present which does not apparently diffuse out of the throat, but continues in action until death is produced from exhaustion, if not from the spinal effects of the poison. The fact, however, that two well-authenticated cases of hydrophobia have recovered during the administration of woorara affords some ground for hope that, with a more uniform and staple preparation of the remedy, or, possibly by reason of the discovery of some new agent which acts in a similar manner, better results may hereafter be obtained in the treatment of hydrophobia.

No similitude in the action of a remedy and the symptoms of a disease can be greater than exists in the case of strychnia and tetanus, a similitude which extends even to their behavior under the influence of opposing remedies. If tetanus were cured by strychnia, it would afford an excellent illustration of the doctrine of similars; but, as it does not, it serves as a striking example of the fallacies of this ancient doctrine. At least six remedies have been used with success in tetanus, viz.: chloroform by inhalation, chloral, tobacco, or its alkaloid, nicotine, bromide of potassium, physostigma, and gelsemium. Although many of them differ in regard to other points of action, they all agree in the power to diminish or suspend the reflex functions of the spinal cord, and act in opposition, therefore, to this distinctive symptom —an exaggerated reflex sensibility. Hence, in poisoning by strychnia, also, the same group of remedies are indicated.

---

* Of the Alumni Association of the College of Physicians and Surgeons, New York.

In convulsions of an epileptiform type some agents that have a similarity of action, and some that act in an opposite manner, are employed. Picrotoxine may be regarded as a good representative of the former, and bromide of potassium of the latter. The first class stimulate the spasm-centre, but as inhibition results when two impressions coming from different points are made simultaneously on the spinal cord, so here the normal equilibrium is the result when the two impressions produced by the disease and by the remedy act on the spasm-centre at the same time. As the action of picrotoxine tends to produce cerebral hyperæmia, it is obviously indicated in these states characterized by anæmia and depression, while bromide of potassium, on the other hand, is most efficient when the patient is plethoric, and the intracranial circulation too active. During the administration of the bromides in epilepsy, the conditions of the faucial reflex affords an indication of the state of the spasm-centre, Voisin having shown that when no movement is caused by touching the base of the tongue, the pillars of the fauces, and the walls of the pharynx, the effect of the bromide is sufficient. A capital illustration of the antagonism between remedies and the symptoms of disease is afforded in the administration of nitrite of amyl for the purpose of aborting epileptic convulsions. No sooner is a whiff of its vapor inhaled than the arterioles become dilated, a light flush takes the place of the deathly pallor which characterizes the inauguration of the paroxysm, the stage of tetanic rigidity does not come on, and, in short, the seizure which was imminent fails to develop.

The principle of antagonism applies equally to the treatment of chorea, and the most successful treatment is that (whatever may be the measures adopted) which has for its objects the maintenance of a quiescent state of the motor centres and the prevention of those irregular discharges of nervous force which constitute the physiognomy of the malady. In certain neuroses of the respiratory and circulatory organs the phenomena of antagonism are exhibited in perfection, and among those characterized by spasm or cramp, with which we are at present concerned, may be mentioned paroxysmal cough, cough by habit, hiccough, whooping-cough, spasmodic asthma, and angina pectoris, which can only be effectually treated by those remedies which oppose the exaggerated reflex excitability. Taking laryngismus stridulus as an example, we find that an irritation of the sensory filaments of the pneumogastric nerve in the mucous membrane, transmitted to the nucleus, is reflected over the motor branches, and the mucles are thrown into cramp—the result being the resounding cough. In order to prevent this reflex act, such agents as chloral, bromide of potassium, and nauseants, which promptly relieve the spasm, are resorted to, and with entire success. Hiccough or singultus, in which a recurring spasm of the diaphragm is supposed to be the condition, affords a good illustration of both modes of antagonism—by similarity and by opposition. If, as I have already mentioned, a strong and rapidly interrupted faradic current be passed at the moment the spasm is about to take place, it is completely aborted, because the powerful irritation of the peripheral fibres induces inhibition. The remedies acting by opposition, on the other hand, are those which diminish or suspend reflex action, such as the anæsthetics, morphia, the bromides, chloral, and nitrite of amyl. To Dr. Lander Brunton we are indebted for the successful use of amyl nitrite in angina pectoris. Ascertaining that in this dangerous condition there was a sudden and powerful contraction of the arterioles, manifested in pallor of the surface, small, strong pulse, labored action of the heart, etc., he proposed the inhalation of this agent to overcome the contracted state of the vaso-motor fibres.

PAIN AND THE ANODYNES.

The same principle of antagonisms holds good in the treatment of pain. Several elements enter into the composition of the sensation which we call pain —the peripheral irritation, the transmission of the impression to the centre, and its realization by consciousness. Hence, pain may be relieved either by interrupting its transmission to the centres of conscious impressions or by suspending the functions of these centres. For example, aconite and gelsemium relieve pain in the former manner, and the anæsthetics in the latter. The anæsthetics, when applied locally, however, have an effect similar to that of aconite, and are, therefore, antagonistic to both peripheral and centric neuralgia. When a few minims of chloroform are injected into the neighborhood of a nerve-trunk, the peripheral expansion of the nerve is put into an anæsthetic and analgesic condition; and since I brought forward this method of treating sciatica, cervico-brachial and intercostal neuralgia, coccydynia, and other neuralgias of nerves in accessible situations, my experience with it has been extremely satisfactory. The needle must be inserted deeply, since merely to inject chloroform under the skin, like morphia, is perfectly useless in such neuralgias, unless the nerve-trunk is in the immediate vicinity. No danger attends this expedient, and inflammatory indurations and abscesses very rarely result from it. The most powerful means for the relief of pain which is now in our possession—the subcutaneous injection of morphia and atropia together—is an illustration of the advantages derived from the study of physiological antagonism. By this combination the anodyne qualities of the two agents are enhanced, rather than diminished, while the disadvantages of each are in a great measure obviated. The combined use of morphia and atropia is also, as has already been shown, the best preventive of the tendency of anæsthetics like chloroform and ether to produce fatal paralysis of the heart or lungs; while the prescription of atropia simultaneously with chloral to a great extent averts the dangers that sometimes attend the use of that agent.

MENTAL STATES AND THEIR ANTAGONISTS.

Antagonism of a mental state by the action of a remedy implies the fact that the mental is a mere symptom of a physical condition. The antagonism between sleep-producing remedies and insomnia is strikingly exhibited in the action of chloral, while the same agent also antagonizes acute delirious mania and acute mania, when these are not due to unchangeable structural lesions. High excitement, with illusions and hallucinations and great motor activity, is controlled by gelsemium, duboisia, hyoscyamia, conium, and other remedies whose action is similar; while melancholia, with torpid movements and suicidal notions, is antagonized by morphia. Acute cerebral congestion of the active form is counteracted by such arterial sedatives as aconite, veratrum viride, and bromide of potassium; and acute congestion of the passive form by ergot, digitalis, etc.; while cerebral anæmia is removed by strychnia, brucia, atropia, quinia, and other excitants. Hence, it follows that mental changes dependent on these vascular states must be largely controlled by the timely use of the appropriate antagonist. Perhaps, also, those changes which are preparatory to cerebral hemorrhage, or which affect the nutrition of the brain unfavorably, may be retarded and possibly prevented by the early use of such agents as ergot, digitalis, quinia, and chloride of barium.

CARDIAC REMEDIES AND DISEASES.

The most exact antagonism has been shown to exist between remedies which act especially on the heart; and we shall now see that there is a similar exactness in the antagonism between remedies and diseased conditions of the heart. If the action of the heart is excessive from a diminution in the energy of the inhibition, we have agents which oppose this state. In that curious affection, exophthalmic goitre, the action of the heart is constantly much too rapid, and is not infrequently excessively accelerated from the diminution in the inhibitive control of its movements, while the carotid artery and the vessels of the thyroid gland are relaxed and dilated. If the malady is treated by the antagonists to such a condition of the heart and vessels before structural changes occur, it is usually small; and these remedies are galvanism (applied to the pneumogastric and cervical sympathetic), digitalis, and ergot, which increase the inhibition and the vascular tension, and thus substitute a slow and regular movement for the wild disorder of the disease. In some affections, such a strong inhibitive influence descends along the pneumogastric that the heart is restrained and its movements greatly retarded; or, again, the heart may be slowed by agencies paralyzing the accelerative apparatus or the motor ganglia. The excess of inhibition is overcome by such an agent as aconite, which depresses the functions of the inhibiting nerve; while the paralysis of the accelerator apparatus is overcome by the stimulants of the motor ganglia, such as atropia. Palpitation proceeding from irregular and explosive discharges of nervous force coming from the accelerator nerves is best controlled by such an agent as bromide of potassium, and palpitation resulting from paroxysmal loss or depression of the inhibition by such an agent as digitalis. The most important antagonist to states of depression (provided certain conditions are observed) is, undoubtedly, digitalis; but I am convinced that the employment of digitalis in the treatment of cardiac weakness is frequently carried much too far. Digitalis increases the inhibition, slows the heart by lengthening the diastolic interval, stimulates the heart-muscle, and facilitates the passage of blood into the coronary artery by increasing the force of the recoil, while it also raises the arterial tension. Long-continued medicinal doses, however, as well as lethal doses, have been proved to exhaust the irritability of the apparatus on which the action of the remedy is exerted; and the practical deduction is, therefore, that digitalis should be given in moderate doses, and not too frequently, on account of the prolongation of its effects. In the condition of fatty heart the use of this agent is more than doubtful, owing to the fact that it decidedly increases the arterial tension, and thus imposes additional labor upon the heart. With mitral lesions the heart is weak and acts quickly (from relaxation of the inhibition), the arterial system has relatively much less, and the venous system much more, than the normal quantity of blood; the arterial tension is low, and the nervous tension too high. Hence, digitalis, as it opposes these conditions, if employed in the proper manner, is indicated, and can be used with advantage; but, as may be inferred from what has just been said, if it is given too frequently or in too large doses, it will cease to antagonize the symptoms on account of which it was prescribed.

The antagonism between remedies and diseases is well shown in the medicinal treatment of aneurism. If the blood-current is slowed, and the calibre of the peripheral vessels diminished, the blood may be caused to coagulate in the sac, when the clot may organize, and a cure perhaps be effected. When Langenbach learned of the success of Hildebrandt in treating uterine fibroids by the hypodermic injection of ergot, he determined to make trial of the same means in the case of aneurisms. His idea seems to have been that ergot, by causing contraction of the muscular fibre of the aneurismal walls, gradually compressed the sac, and thus effected a cure. It has been urged, accordingly, that ergot injections could be of no service in aneurisms of the aorta, since the latter has no muscular coat; but those raising this objection seem to have forgotten the important fact that the solidification of the sac is produced by the coagulation of the blood within it, as well as that the conditions most favorable to such coagulation are a slow action of the heart and increased tension at the periphery, both of which result from the injection of ergot.

In the arrest of hemorrhage the same principles of antagonism are depended upon. No one now thinks of trusting to opium, acetate of lead, tannin, sulphuric acid, and the medley of ancient astringents. Modern pharmacological research has placed in our hands the most efficient remedies for hemorrhage, which are agents whose action is antagonistic to the conditions from which the hemorrhage results. These conditions are increased action of the heart and relaxation of the vessel-walls, and the most efficient remedies in antagonizing them are ergot, digitalis, bromide of potassium, veratrum viride, etc. In arresting pulmonary hemorrhage the subcutaneous injection of ergotin is the most prompt and certain means at our command, while menorrhagia is usually more speedily arrested by bromide of potassium. These remedies may be given in combination with good effect: bromide of potassium and digitalis by the mouth, and ergotin subcutaneously. The application of cold and heat for the purpose of arresting hemorrhage is based on the same principle. The first effect of cold is to cause prompt contraction of the arterioles; but this is followed by their relaxation. Heat, on the contrary, first causes relaxation, and subsequently, contraction—the latter being more energetic than that which is primarily caused by the application of cold.

RESPIRATION REMEDIES AND DISEASES.

I have already dwelt sufficiently upon the action of those remedies which are employed to antagonize the neuroses of the respiratory organs. As to those which have a depressing effect upon the function of respiration, it will be enough to remark that the only purpose to which they can be applied with advantage is to impose rest on the breathing organs by diminishing the number and force of the respiratory efforts. As regards the agents which stimulate this function, much good results from their timely use. Strychnia, as has been pointed out, is a respiratory stimulant of great activity, and of much value in suitable cases. In the carbonic acid narcosis, which results from respiratory failure in acute pulmonary affections, and in some cases of emphysema and chronic bronchitis, it is antagonistic and undoubtedly of the greatest service; and probably no remedy so generally prevents the reflex nausea and vomiting which occur in phthisis. In capillary bronchitis, when hæmatosis is suspended and carbonic acid narcosis comes on, and in pneumonia when abortive attempts at crisis are made, it seems altogether probable (on theoretical grounds) that the hypodermic injection of strychnia would prove of great service. The utility of strychnia in chronic bronchitis and bronchorrhœa, however, is attested by an immense experience.

But, as a rule, atropia is a more useful respiratory stimulant than strychnia. It is frequently employed in certain neuroses of the lungs, but its greatest usefulness lies in its power to increase respiration when depressed from a variety of causes. Not only does it stimulate the respiratory centre, but it also diminishes the irritability of the sensory nerves of the lungs, and increases the circulation through these organs. In caseous pneumonia, before the process of softening and extension of the caseous matter has begun, atropia frequently has a distinctly beneficial effect upon the local lesions, as well as the general state.

INTESTINAL REMEDIES AND DISEASES.

In the diseases of the intestinal tract the action of antagonistic remedies is well shown. Thus, a serous diarrhœa is promptly averted by the use of belladonna. Opium suspends intestinal movements and stops secretion, and therefore relieves conditions of an opposed kind, viz., diarrhœa and dysentery. Constipation depending on torpor or paresis of the muscular layer of the bowel, is often promptly cured by the faradic current. When the muscular coat is paretic and secretion is deficient, the relief afforded by antagonistic agents is very remarkable; and the appropriate agents opposed to this condition of things are nux vomica, belladonna, and physostigma.

REMEDIES ACTING ON THE SKIN.

In the night-sweats of consumption, atropia, duboisia, hyoscyamia, and other similar remedies antagonize the conditions present, and dry the skin, the value of this treatment being very great on account of the immense loss of material which takes place through the skin. Sometimes the remedies acting by similarity, such as Dover's powder, pilocarpine, and picrotoxine, have a good effect; but their action is much less certain and permanent, and they should never be resorted to in this connection unless the other class of agents have failed. When there is a deficiency in the quantity of cutaneous secretion, sudorific agents may be called for, and the most prominent of these is pilocarpine. Picrotoxine has also some value as a sudorific, but is far inferior to the latter. Local sweating can usually be arrested by the application to the part of belladonna or atropia. The milk-gland being in reality a sweat-gland, with peculiar characteristics on account of its special office, is acted on by antagonists in a manner similar to the skin. Thus, pilocarpine increases the flow of milk, while atropia diminishes or arrests it.

REMEDIES ACTING ON THE KIDNEYS AND BLADDER.

As one would naturally suppose, from the vicarious action of the skin and the kidneys, those remedies which act on the skin are antagonistic to those which stimulate the renal secretion.

A condition of diminished activity of the kidneys is opposed by those agents which have a special diuretic action. Substances excreted by the kidneys and acting as irritants promote the urinary discharge, as copaiba, cubeb, turpentine, etc.; but these are not proper antagonists. Remedies such as digitalis and squill, which increase the pressure in the renal vessels, and also directly stimulate the secretion, are the proper antagonists to the state of diminished activity.

Very admirable results are obtained in vesical irritability by the appropriate and timely use of antagonists. Thus, in the form of this which is usually seen in women, where there is an excessive intolerance of the presence of urine in the bladder (though the mucous membrane is unaffected and the urine unaltered), complete relief is often afforded by the use of tincture of cantharides. The treatment of nocturnal incontinence of urine is most effective when based on antagonism of action, and this affection demonstrates how, in the search for antagonists, we must carefully study the physiological pathology of the disease. If it depends on weakness and relaxation of the sphincter, belladonna and ergot would be the appropriate remedies; if on intolerance of the mucous membrane, bromide of potassium and alkalies; and if on the irritability of the muscular layer of the bladder, such remedies as gelsemium, conium, and chloral would be called for.

Original Communications.

THE MANAGEMENT OF ECZEMA OF THE ANUS AND GENITAL REGION.

By L. DUNCAN BULKLEY, A.M., M.D.,

ATTENDING PHYSICIAN FOR SKIN AND VENEREAL DISEASES AT THE OUT-PATIENT DEPARTMENT OF THE NEW YORK HOSPITAL;
LATE PHYSICIAN TO THE SKIN DEPARTMENT,
DEMILT DISPENSARY, NEW YORK, ETC.

(Read before the New York Academy of Medicine, December 2, 1880.)

The misery endured by patients affected at all severely with eczema about the anus or genital region can be little understood except by those who have thus suffered, or who have had much to do with those thus afflicted. From the number of these cases which have come under my care, and from their previous duration, I fear that the importance of the disease in this locality is not fully appreciated by the profession, and that the measures which will give permanent relief are not as well understood as they might be. It has occurred, therefore, that a practical consideration of the subject might not be without interest at the present time, hoping that thereby some may be enabled to give relief to many of these distressing cases, whose existence, I am sure, is far more common than is generally supposed. Thus, of 700 cases of eczema occurring in my own private practice, there were seventy-three in which these parts were invaded, or over ten per cent. of the whole number. The records of my dispensary and hospital cases have not been kept with sufficient accuracy to allow of analyzing them in this respect; but, from the very many instances which I have seen in public practice, I think I do not exaggerate in placing the ratio at at least one-tenth of all the cases of eczema. That statistics do not represent the real frequency of the disease is evident, for I know that sufferers from eczema of the anus or genital region often, if not generally, hide their trouble until it is no longer bearable; especially is this true of females. The reasons for this concealment are several. Shame undoubtedly prevents many from exposing disorders of these parts to the knowledge of others. The idea is more or less prevalent that any disease in this region may have some connection with sexual transgressions. Again, many with eczema of the anus imagine that they have "piles;" indeed, cases of this trouble very often pass among the general profession as "itching piles," while, of course, every disease about the anus is thus named by the "pile doctors" to whom these unfortunates often apply. Eczema about the genital folds also often passes for simple chafing, until it is deep-seated and the long continuance of the causes and results have rendered the condition very rebellious to cure. Still another cause operating for the continuance of these cases and neglect of treatment, it must be acknowledged, is the feeling which has long pervaded the people that disease affecting the skin is a special dispensation of Providence, which it is wrong or useless to interfere with, or which will in some way right itself; while, no doubt, there has been also the feeling that affections of the skin were not amenable to treatment to the same degree as are other maladies. Happily, popular and professional scepticism in regard to the success of the treatment of skin diseases is fast passing away before the rapid progress which has been made in dermatology within the last five-and-twenty years, so that this once-neglected department may now be reckoned one of the most certain branches of medicine, if, indeed, it is not the most certain and definite in the matters of diagnosis and treatment.

Eczema of the anus and genital region does not differ essentially from the same disease as manifested elsewhere, and my object in treating of the eruption in this particular location is to call special attention to its frequency, its obstinacy if not properly managed, and last, but not least, to some of the measures which I am constantly using with success in its removal. While, as has been remarked, the disease does not differ in nature from eczema of other parts, there are some peculiarities in its phenomena and their treatment to which it may be well to call particular attention, for the text-books are meagre so far as relates to this special manifestation of eczema.

Acute eczema of the anus is not very common, but is seen more or less frequently on the genitals. Its management generally presents but little difficulty, and differs little, if any, from that of service in a similar state elsewhere. Rest, absorbent powders, or lotions with a powder in them, generally suffice. The present paper has to do with those many cases of chronic eczema where the disease or irritation has lasted for weeks, months, or years.

All degrees and grades of this eruption may be observed in the regions under consideration, and often those cases presenting the least external signs will give the most distress. About the anus we may sometimes have but a slight amount of thickening of the muco-cutaneous surface, with a little purplish congestion and perhaps a few rather superficial excoriations or abrasions in the folds of the opening, and yet the distress with itching and pain may be intense, and prevent or greatly disturb sleep, and even rob the patient of peace and comfort. Or, again, there will be very little to be seen on a scrotum, except some marks of scratching, and, on close examination, only a moderate thickening of the skin is felt on pinching the part, and yet the annoyance or even distress of the itching will be such as to be a real burden to the patient. We may also have much the same state of affairs existing about the female genitalia, and, though not presenting much to the eye, the condition may be the occasion of great suffering. In each of these instances there is a deep sensation of itching, for which they will pinch, or press, or rub, or scratch the part, and even thus can only with difficulty reach the seat of annoyance; nor can these patients by force of will abstain from thus seeking relief.

Many of these cases have been called pruritus, or even prurigo of these parts; but in by far the larger share of cases the real trouble will be found to be an eczema, which sooner or later would or does develop into more characteristic features.

But the really severe cases show, of course, manifold more external signs of the disease, and we may have the entire anal region the seat of a greatly thickened, red, moist, exuding surface. Very often the condition even seems to be only a whitened, soggy state of the parts between the buttocks, the natural furrows in the mucous membrane being deepened, and some few abrasions being seen. This condition gives rise not only to periodical or permanent itching, but even to great pain on sitting, or during defecation. This state may affect the region of the anus alone, or may extend to and involve the entire male and female genital region; or these latter may be affected alone even to a very severe degree without the process extending to the region of the anus.

Eczema of these regions is by no means always associated with eczema on other parts of the body, for in some of the worst cases which I have been called upon to treat there has been no sign of cutaneous disease except upon the anus or genitals, or both, although I have also frequently seen it associated with a similar eruption elsewhere, or with a history of preceding eczema of other parts.

I will not occupy your time with entering upon the exact clinical features of eczema in the locations under consideration, or of the differential diagnosis from other lesions likely to occur here. I will only remind you of the absolute necessity of a correct diagnosis in this as in other diseases of the skin, without which, of course, no management can be successful. This remark is not as unnecessary as it may appear to some, for I have seen a number of cases where quite different states have been regarded as eczema by those who had previously seen the case.

It is well always, as a matter of routine, to eliminate the matter of pediculi pubis, for they may be sometimes found, as also the other varieties of the pediculus, even in the highest walks of life, and may give rise to an itching which closely resembles that of eczema, and the subsequent scratching may cause abrasions simulating this eruption.

Scabies should always, also, be borne in mind, for in males lesions are very commonly found on the penis and scrotum, and it would be quite possible for the manifestations elsewhere to be very light, or to have been removed by treatment while they remained on the penis or scrotum. Or, again, very severe treatment for scabies may have left behind it an artificial inflammation resembling eczema.

One of the most common complications of eczema in the genital region, and also the lesion which perhaps is most often mistaken for it, is the vegetable parasitic eruption, the so-called eczema marginatum, or ringworm of the thigh—tinea trichophytina cruris. As remarked, this may be a separate affection or it may complicate an eczema, and occasionally we observe at one and the same time the characteristics of the parasitic disease: the sharply defined margin, advancing as the surface clears more or less behind it, and the irregular, blotchy patches of eczema near by. The eczema may exist first, and the parasite, finding an appropriate soil, may grow upon it; or the parasitic eruption may be of old date, and the eczema may develop upon it from the severity of the itching and the stimulant applications given to relieve it, or from the scratching itself. Now, unless this parasitic element is recognized and met therapeutically, the case will prove most rebellious.

On a number of occasions I have seen syphilitic lesions about the anus and genital region which had been called eczema and treated as such. I need but suggest this, for the lesions of the two are so markedly distinct when carefully considered that they should never be confounded.

Herpes of the genital organs is more frequently mistaken for venereal ulcers, but may also resemble eczema in a measure, and should always be differentiated.

Finally, many cases of pruritus of these parts undoubtedly do occur which should not be classed as eczema, although, as remarked first, more cases are probably classed as pruritus and prurigo of these regions which are in reality eczema, than there are cases of pruritus which are called eczema wrongly. On several occasions I have seen the pruritus accompanying glycosuria develop an eczema, and I have seen as a further complication a distinct eczema marginatum or ringworm formed later.

This is not the time or place to enter upon an extended study of the nature or causes of eczema in general, nor to give views as to its prognosis. As regards, however, eczema affecting the regions under consideration, I may say that I do not regard it as of local origin, but that it invariably indicates a state or habit of body which, unless it is properly reached, will certainly render the affection incurable. On the other hand, I firmly believe, and know from experience, that if careful, proper, and sufficient care be taken of these cases in every respect, they are most certainly curable, and that permanently; unless, indeed, the patient again transgresses all rules and excites a fresh attack, which need not happen, and which is rare in those who have been faithfully treated. I refer, of course, to the intelligent patients of private practice, for, however valuable public practice is for diagnosis and teaching. far less reliance can be placed on therapeutical deductions there formed than on those obtained by the careful study of private patients.

It will be understood here, however, that I by no means ignore local causes as determining agents in the production of the eruption at any particular place and time, for this is confirmed in regard to eczema of other parts as well. Thus, I have no doubt but that the irritating nature of some vaginal and uterine secretions may provoke a pruritus which may end in an eczema. Also, the perspiratory or sebaceous secretions of the parts in question may perchance be more irritating than usual, or may have been confined and become decomposed, and thus act as a local excitant; a neglected erythema intertrigo may develop into a very intractable eczema. Irritating underclothing, as also bad water-closet paper, may afford the primary cause, and perhaps many other local elements may be of more or less importance, and should, of course, be taken into consideration in the management of the eruption.

But all these—indeed, many local causes may exist in certain individuals and yet never provoke an eczema; and they may even have occurred to the same person on previous occasions and yet have proved innocent. There certainly is some other state or element which requires to be recognized and met in order to give these patients perfect and permanent relief.

The most common single, general symptom observed in patients with eczema of the anal or genital region is constipation, or, as it might be more properly called, imperfect intestinal excretion, generally with faulty liver-action; indeed, this almost invariably exists to a greater or less extent, and requires to be looked for and managed properly. So commonly have I found this in the very considerable number of cases of eczema of the anus and genital region which have been under my care, that I had felt that I could almost state it to be an invariable accompaniment of this condition; but, on going over my notes of cases, I find a certain small proportion in whom it is stated by the patients that the bowels acted regularly once or twice daily. This is not, however, convincing proof to me that the intestinal action was perfect, and I still believe this to be the most important single factor in the disease. Quite possibly the irritating character of the excrement itself is an efficient local cause of the presence and continuance of the eruption.

This imperfect intestinal excretion should be corrected, if possible, and very great care will sometimes be necessary to accomplish this. It is not enough to give occasional purgatives, nor even to prescribe daily laxatives; for, unless much caution is exercised, the ultimate result in this direction may be bad instead of good. These remarks in regard to the management of this important element may seem trite and out of place before this learned body, but I wish to impress the very great importance of dealing with this portion of the treatment rightly as a *sine qua non* of the successful management of eczema of the parts under consideration.

All the elements which conduce to bring about a healthy action of the bowels and organs of digestion must therefore be attended to, and, consequently, in the treatment of eczema about the anus and genitals we must not be content with a few general directions, or the prescription of one or another purgative or laxative remedy. On the contrary, it may require no little trouble to ensure a healthy evacuation of the bowels daily, and this is accomplished by diet, exercise, regularity in attending to the call of nature, and such assistance from medicine as may be necessary.

A very common accompaniment of eczema of the regions under consideration is a greater or less congestion of the portal and hemorrhoidal circulation, manifested by a purplish congestion of the mucous membrane of the anus, or very commonly by a greater or less degree of internal or external piles. These latter may not be sufficient to be recognized by the patient, and yet be an element indicative of the existing state which must be regarded. It is well, therefore, in examining patients thus affected, to have them strain or bear down to bring the deeper portions to view.

When this congestion of the hemorrhoidal vessels exists I almost invariably give the time-honored mixture of precipitated sulphur and cream of tartar, in quantity sufficient to secure one or two loose movements from the bowels daily. I never give it with syrup, as I believe this often ferments or acts prejudicially in the stomach, and in a measure impairs the good effects. I order a mixture of the sulphur and bitartrate of potassa in equal quantities, and direct that from one to two teaspoonfuls be taken at night on retiring, rubbed up with water into a paste. The dose is not a very pleasant one, but it is readily taken, even by ladies.

Where there is no marked hemorrhoidal congestion I employ a pill of two grains and a half each of blue mass and compound extract of colocynth, with a quarter of a grain of powdered ipecac in each pill; two such pills to be taken at night and two on the second night after, followed each morning by a seidlitz powder or Kissingen water. These pills are to be taken only twice, and are not resorted to again at a less interval than a week or two; but they may be thus used repeatedly with good effect.

If there is simply a sluggish action of the bowels, I have had most excellent results to the accompanying eczema from the use of a pill composed of half a grain of the extract of socotrine aloes with a grain of dried sulphate of iron and a little aromatic powder and confection of roses, one pill being taken directly after eating. Very much may be accomplished by this combination in the way of permanently overcoming the constipated habit if the pills are employed regularly and systematically according to the following directions: at first one pill is taken directly after each meal, three times daily; in a few days the noon pill is omitted, and a few days later one is taken after the evening meal only, and soon this is required less frequently, and subsequently omitted. The point to be insisted on is that the pills shall be used regularly in the above manner until the bowels acquire the habit of daily excreting and discharging a normal amount—if they are taken irregularly simply for a cathartic action, no ultimate good results follow; but I can bear testimony very strongly to the value of this plan of treatment, and could adduce many cases where this has constituted one of the chief means of speedy and permanent cure of long-standing cases of eczema of the anal and genital regions.

It is a very common custom with many to give mineral waters to these patients, with the simple direction that they keep the bowels open therewith. In my experience this is an unwise procedure, and I believe that many persons are to-day suffering from constipation and consequent eczema of the lower region because of the constant stimulation of the intestinal tract with these or other purgatives, while the cause of the intestinal inactivity—sedentary habits, over-indulgence at the table, etc.—has been allowed to go on unchecked. I never order mineral waters to be taken for a length of time, and constantly discountenance their use.

Nor is it at all sufficient, in these cases, simply to secure an emptying of the lower bowel by means of an enema, even if employed daily. In my judgment enemata are to be used only very rarely, for a definite purpose, and the habit of a dependence upon water injected to excite the intestines to contraction is worse even than to have them depend upon mineral water poured into the other end of the digestive tube. Nor will an action of the bowels secured by enema at all help an eczema of the anal or genital region; for I have seen some very bad cases of the eruption in this locality where this means of emptying the bowel was practised.

I will not here enter more largely into this subject, which is a prolific one, nor will I detail further remedies which might be of service; but I have dwelt on it thus long because the more I see of these cases the more convinced I am that imperfect liver-action and imperfect intestinal excretion are at the bottom of very many of them. As mentioned before, he will but poorly treat these cases who contents himself with prescribing in a routine manner this or that remedy which has been proposed or vaunted, and he will but poorly manage the intestinal excretion who is satisfied with giving casual prescriptions to loosen the bowels. The physician must give definite instructions to the patient in regard to his mode of life, diet, and hygiene, and must even extend it to securing that the call of nature, though it be light, be answered promptly at a regular time each day, preferably after the morning meal.

Next to imperfect bowel-excretion I would place deficient kidney-action as an element to be regarded in the cases under consideration. The urine of these patients is seldom that of health; the most varied conditions may be reported, but not at all infrequently it is recognized by the patient as leaving a deposit in the chamber and staining the same. Frequent and imperative micturition is not at all uncommon, and the repeated calls to urinate at night and the itching will often act and react on each other, rendering sleep almost impossible.

Most of these cases, therefore, require also an alkali, and I find the best results from acetate of potassa with a bitter, as in the following mixture:

℞. Potass. acetatis.................. ℥ j.
Tinct. nucis vomic................ ʒ ij.
Infus. quassiæ.................... ℥ iv.
M. Teaspoonful after eating, in water.

This is often continued during the entire course of treatment, and frequently for some time after the complete disappearance of the eruption and cessation of all itching.

Not infrequently, however, cases of eczema of the anus and genitals will be associated with a large amount of oxaluria, and will be quickest relieved by the strong nitric acid internally, in doses of about two drops after eating. The well-known mixture of sulphate of magnesia, sulphate of iron, sulphuric acid, and infusion of orange-peel, is sometimes of much service, especially when there is a tendency to sluggishness of the bowels, which does not remain corrected with diet, etc., after a course of the pills mentioned.

In some cases the disease is largely due to simple debility, and iron and other tonics which give life and tone to the system will do the most good to the eczema, often in the way of rendering the processes of assimilation and disassimilation more perfect, whereby the liver, bowels and kidneys share the healthful activity.

These are the main internal remedies of service in this oftentimes very troublesome affection, and if the homely measures I have briefly alluded to are faithfully carried out and combined with proper local applications, they will, I am confident, secure the permanent removal of a complaint which is at this moment rendering many individuals very uncomfortable, if indeed it is not in some cases almost making life a burden.

It will be noticed, perhaps, that arsenic has not been mentioned, and yet I am positive that one-half of the general practitioners would give arsenic at the first visit to one suffering from the conditions under consideration. I will say that I had *not* purposely omitted mentioning arsenic, but that merely it had not occurred to me to speak of it, because, probably, I so seldom use it for these cases. When there is a marked eczematous habit, and when, after all the above measures have been attended to, and others perhaps in the same line, if then there remained a tendency to the disease, I might and do employ it in connection with other remedies, but never as a curative measure at the beginning of the case, and especially never in cases presenting acute symptoms. As a modifier of the nutrition of the skin, arsenic holds a high place among other medicines, but not as a controller of congestion or inflammatory action.

If internal and general measures are important in eczema of the anus and genital region, local measures are, if possible, of even greater importance; it is much not to do the wrong thing, and still more to do just the right thing. This remark is made because one occasionally sees cases which have been greatly aggravated by previous treatment, which yield promptly to proper measures. The main point to be ever borne in mind in the treatment of these parts is that more harm than good may be done by too strong applications, and that the soothing plan must be followed as far as possible, certainly while there are signs of inflammation, stimulating measures being adopted only in later stages of treatment, and to remove the remains of the disease, as thickening of the skin, and not for the arrest of the eczema.

The itching of these cases is often most intense, and the patient will plead that if he can only have something to stop the itching the disease will get well. And so I have repeatedly had cases where all sorts and kinds of measures had been previously prescribed with a view of arresting the itching, but in vain, whereas the case yielded speedily when complete treatment was instituted, including only very mild local measures. Quite recently a physician brought a patient in consultation, not in regard to any general management of the case, but only to have my opinion in regard to the probable utility of applying the actual or galvanic cautery to the parts to arrest the itching. And so I have had cases which had previously been given stronger and stronger local applications, with a view of checking the itching, after the failure of recognized neurotic local remedies, until the parts had been brought to a terrible state of inflammation from such applications as strong citrine ointment and the like. Now, while these may succeed in some cases in which, perhaps, a transient, digestive disturbance was the starting-point of the eczema, I am confident that in the main all such attempts in the way of a local treatment of eczema in these parts is false in theory and injurious in practice.

The measures which I am about to detail may be simple, but will in most, if not all cases, be sufficient as local treatment, provided that all else has been carefully attended to as implied in the preceding brief mention of dietetic, hygienic and internal medication.

I place great reliance upon hot water as a means of relieving the congestion of the parts and the consequent itching. But the water should be indeed hot, and not warm—so hot that the hand cannot be thrust wholly into it—and it should be used in exactly the manner now to be described. I speak thus positively because I occasionally hear it asserted by patients that it is not of service, and on inquiring I find that the exact rules have not been followed, or that it has been used for a longer time or oftener than prescribed. The patient should sit on the edge of a chair and have a basin with the very hot water and a soft handkerchief in it. This latter is then picked up and held in a mass to the anus or genital parts, as hot as can be borne, say for a minute, and then dipped in the water again, and the process repeated three times, the whole not lasting more than two or three minutes; too long bathing, or too frequent sopping of the part or rubbing with the cloth, etc., makes matters worse.

Before the hot water is gotten ready, I have the ointment which is to be employed spread thickly on the woolly side of surgeon's lint, cut of a size to cover the affected parts only, and laid close by ready for immediate use. After the parts have been soaked with the hot water for the prescribed time, they are rapidly dried by pressing a large, soft linen napkin upon them, with absolutely no friction, and the already spread cloths are immediately applied, the object being to at once exclude the air entirely. Ordinarily it is necessary to use the hot water only a single time in the twenty-four hours, namely, after undressing, and when ready to get into bed. It must be premised that the patient is to so manage as not to indulge in the usual scratching before undergoing these manipulations. If this desire is given way to beforehand, the treatment will not always control it at once; but if the patient can avoid even touching the parts except as described, he or she will commonly be quite able to go to sleep immediately. I have repeatedly had those thus afflicted say that the first night of treatment was the first real rest they had had for months or years.

If the case is very severe, and if there are spells of recurrent itching, the hot water may be repeated occasionally; but it is commonly sufficient simply to renew the ointment one or more times in the day, especially in the morning on rising, without the repetition of the hot water, which latter, I think, sometimes acts prejudicially in softening the parts if used more frequently. It should be added that the ointment should always be spread on lint and never be rubbed to the part; also, that in applying the lint it should be kept in close apposition to the diseased surface, and that by means calculated to heat the parts as little as possible; and finally, that in renewing the dressing the fresh cloth should be spread and ready, near by, before removing the previous one, that the access of air to the parts may be prevented by changing the coverings as quickly as possible.

The ointments employed must vary somewhat with the case, and no single one could be mentioned which would be invariably of service. That which I most commonly prescribe is made as follows:

℞. Unguent. picis.................... ℥ j.
Zinci oxidi....................... ʒ ij.
Unguent. aquæ rosæ (U. S. P.).... ℥ iij.
M.

This should be of a consistence which spreads easily and remains soft, which may be easily regulated by varying the proportion of the spermaceti in the rose ointment or cold cream. I may add that I never employ the recent products of petroleum, cosmoline and vaseline, as a basis for these ointments where protection of the surface and exclusion of air is desired, as they have not body enough to remain as a thick coating upon the limb, but rapidly soak in and leaves the parts dry and exposed.

I will not occupy time with further details of ointments, as this is sufficient to indicate the plan or idea of treatment which I wish to present as offering success in the class of cases under consideration; while the ointment is not a matter of indifference, the same result can be obtained I believe by other remedies than the one mentioned, and my case-records would undoubtedly show many others of value. It is the method of employing remedies and strict attention to details which gives success, and I feel certain that the points I have given are very important and will be of the greatest service if carefully carried out.

Brief mention might be made of other applications which have rendered me good service, although, as before remarked, remedies must vary for different cases, and it is beyond the limits of the present paper to detail all that might be used and to give their possible indications. The following combination is very effective:

℞. Unguent. picis	ʒ iij.
Unguent. bellad.	ʒ ij.
Tinct. aconit. rad.	ʒ ss.
Zinci oxidi.	ʒ j.
Unguent. aquæ ros.	ʒ iij.
M. Ft. ung.	

The ointment of chloral and camphor, of each a drachm or two to the ounce, will often prove a very efficient anti-pruritic, as first described by the present writer several years ago.

Lotions are sometimes of much service, especially in eczema of the penis and scrotum, and the following can be recommended:

℞. Bismutha subnitrat.	ʒ ij.
Acid. hydrocy. dil.	ʒ j.
Emuls. amygd.	℥ iv.
M. Ft. lotio.	

This of course must not be used where the skin is much torn or broken.

A word may be added in regard to the employment of stronger local measures, for they are not infrequently of value in proper cases and at the proper time or period in the disease. When congestion has ceased, and there is still some thickening and a tendency to slight cutaneous fissures, we may use the green soap or the compound tincture of green soap.

℞. Saponis viridis,	
Olei cadini,	
Alcohol	āā ℥ j.
M.	

with good effect. With this we need friction, and a piece of muslin (subsequently white flannel may be used to give greater friction) is wet with the lotion and rubbed briskly over the parts for a few moments, which are then to be immediately covered with a mild ointment. For this purpose the ordinary zinc ointment, half a drachm to the ounce of the unguentum aquæ rosæ (U. S. P.), answers well, or the subnitrate of bismuth, or calomel, either in the same strength. We may also use with good effect the unguentum diachyli of the German Pharmacopœia, as introduced by Hebra; but this is apt to be too stimulating for some skins. It is quite as well not to have any tar in these ointments, because, having stimulated with a tarry lotion, the parts need complete rest. We may sometimes obtain excellent results from the use of caustic potassa in solution, used in much the same way, but some caution will be necessary in order not to overstimulate the part. A lotion of five to ten grains to the ounce is all that can be borne in many instances; but if carefully applied, especially by the physician, one of the strength of fifteen, thirty, or even sixty grains to the ounce, may be quickly brushed over the part, and cause an exudation which is followed by relief to the itching and diminution of the disease. These strong applications are to be advised with caution, and care should be taken that soothing measures, as cold-water dressings, are employed afterward.

When the tendency to slight fissures of the mucocutaneous fold still remains, we will have great benefit from touching the latter carefully with a stick of pure nitrate of silver, and afterward packing in a little cotton upon the parts. But I must advise this also with caution, because one of the worst cases of acute eczema of the scrotum and anus which I ever had under my care, and which had confined a gentleman to bed for several weeks, was started up by having an old eczema of the anus thus touched with lunar-caustic by a gentleman of great eminence in the profession; in a case of my own also, there was very considerable inflammation excited by a similar application made by myself, but it passed off in a day or two, and with great subsequent benefit to the parts.

Time does not permit me to go into the subject more fully, though there is very much more which might be said. Eczema about the female genitals presents some features still different from those mentioned, and often proves very rebellious, but is in the main entirely amenable to very carefully directed treatment on the plan of that here detailed, and that in a reasonably short time. When considering the matter of diagnosis, mention was made of the frequent occurrence of a vegetable parasitic eruption about the genital region, the eczema marginatum of former writers, and of the liability of confounding it with eczema of these parts. The rather sharply defined border of the eruption and the tendency to clear in the centre are points which will first attract attention to this tinea or ringworm of this region, and frequently, though not always, the parasite, the same as in tinea tonsurans and circinata, may be made out in the scales by the microscope. When this is determined to exist, we may at once use anti-parasitic remedies, or it may be necessary first to treat the eczema element for a while until the acute inflammation has in part subsided, in the manner previously detailed, and afterward the parasiticide may be applied without causing irritation. The parasiticide which I most frequently employ is the strong, undiluted sulphurous acid, freely bathed on the part, which will give the greatest relief to the itching, and if persisted in will singly and alone cure the case. But, as I have frequently mentioned elsewhere, the sulphurous acid must be fresh (and I always instruct the patient to procure an original, unopened package), for, if used as ordinarily found in the drug-shops, it has altered by constant exposure to the air, and the SO_2 has become sulphuric acid, SO_3, and is of course very irritating and not efficient as a parasiticide.

Eczema of the anus and genitals is not infrequently seen in children, and causes great distress. I have had a number of cases which had been rebellious, but which yielded to the principles already discussed.

In closing this rather elementary and somewhat desultory paper, I have to beg your indulgence for its imperfections. I preferred to present a homely subject in a practical manner, rather than to detail new observations or relate rare cases, because I believe that our province is to cure disease and alleviate human trouble. If, therefore, I shall have assisted any one in managing eczema of the anal and genital regions, which I know to be most distressing to those afflicted with it, I shall be content and shall willingly bear the odium of going over hackneyed ground, and perhaps of presenting much that was already known to some, if not all, of my hearers.

CASES OF PROLAPSUS ANI

Successfully Treated by Hypodermic Injections of Strychnia.

By LEONARD WEBER, M.D.,

NEW YORK.

Nélaton was the first, I believe, to recommend the use of strychnia for the cure of simple prolapsus ani. Whether he or any one else had used strychnia hypodermically for that purpose before I did, in 1868, I do not know.

In that year I was consulted by a merchant, about forty-five years of age, who had suffered from prolapsus ani for three years. It came on after a prolonged attack of dysentery. Not more than one inch of mucous membrane protruded.

It was easily reduced, but as readily came down again. Sphincter very weak and dilatable, but control over bowels satisfactory. At stool he would often lose small quantities of blood, and a slight but constant sero-sanguinolent discharge from the protruded mucous membrane was quite annoying to him. The usual remedies had been applied without success, and to the application of nitric acid, or the actual cautery, I could not persuade him to submit. It occurred to me to inject strychnia hypodermically. Inserting the needle about three-fourths of an inch from the anus, and directing it upward and parallel to the gut, I injected one-twelfth of a grain of the remedy, repeating the injection in forty-eight hours upon the opposite side, and continuing in this way until six injections had been made. The pain accompanying the injection was insignificant, no inflammation or abscess followed, the bowel ceased coming down, and the cure then effected has been permanent.

Case II. (1870).—Boy, eight years old, somewhat anæmic, muscular system poorly developed, had had repeated diarrhœal attacks. His mother said his "body" had been coming down for a long while. Prolapse half an inch. Sphincter very weak and dilatable. I injected one-eighteenth of a grain as above. The relief was complete after eight injections, given in the course of four weeks.

I have lost sight of this patient, and do not know whether the cure has been permanent.

Case III. (1877).—Boy, four years old, healthy and strong; prolapse of three-fourths of an inch, quite reducible, for about a year. Cure after four injections of gr. $\frac{1}{24}$ of strychnia, each given as above. Patient has remained cured.

Case IV. (1878).—Boy, five years old. No organic disease, but rather weak; troubled by frequent epistaxis. Prolapse nearly one inch long, in consequence of dysentery. Has had it for eighteen months, and been unrelieved by treatment so far. Four injections of gr. $\frac{1}{24}$ of strychnia each were made, when the patient ceased coming to the office, and was lost sight of.

Case V. (1879).—Girl, six years old, somewhat anemic, but well developed. Prolapse of half an inch, with considerable sero-sanguinolent discharge from the protruded mucous membrane, and occasional loss of blood at stool. It had existed more or less for two years, and had also followed dysentery. Cure after four injections of gr. $\frac{1}{24}$ of strychnia each. Patient has remained cured.

This was the only case in which I had to etherize the patient, owing to her excessive fear of being hurt. In all five cases the usual local and general treatment, tonic and astringent in character, had been tried without any benefit.

A speedy and permanent cure I know to have been obtained by the injection of strychnia, *in loco morbi*, in three cases. No pain of any consequence was inflicted by the procedure, nor unpleasant symptoms, inflammation or abscess, followed the injections. No such results have been obtained in my practice, in similar cases, by other remedies short of severe surgical measures.

It appears, then, from the record of these cases, that the hypodermic injection of strychnia *in loco morbi*, in cases of simple prolapsus ani, has a direct and rapid effect upon the sphincter muscles, re establishing the physiological tone after comparatively few injections. This mode of treatment is perfectly safe, and apt to effect a speedy and permanent cure.

136 W. Thirty-fourth Street, New York.

Progress of Medical Science.

Extra-Peritoneal Ovariotomy.—W. A. Meredith records in the London *Lancet*, August 21, 1880, the following case as offering an example of a completely extra-peritoneal ovarian cyst. He has seen but one other at all resembling it in nearly three hundred abdominal sections at which he has assisted. Patient, a delicate-looking woman, aged twenty-seven years, gave the following history: Menstruation occurred for the first time shortly after her marriage, at the age of twenty-four; the flow, which was scanty, recurred at irregular intervals during the first two years of married life, but for the last eighteen months she had seen no further signs of it. She had never been pregnant. Shortly after the last appearance of the menses she noticed some increase of size in the abdomen, and was troubled with dragging pains in the left side. This swelling suddenly began to diminish coincidently with the passing of a considerable quantity of clear, pale urine. Six months subsequently the pain and swelling returned, accompanied by considerable discomfort from flatulence. Upon examination the abdomen was uniformly distended by an elastic, indistinctly fluctuating tumor, which extended upward to about midway between the umbilicus and the xiphoid cartilage. Palpation conveyed the idea that the growth was closely adherent anteriorly to the abdominal wall. Fluctuation was at first tolerably evident, but became less distinct owing to increased tension. The percussion note was clear over the epigastrium, the resonance extending downward somewhat below the umbilicus; it was also clear in the right lumbar region, but absolutely dull in the left flank. The girth at the umbilical level was thirty inches. On pelvic examination a cyst was felt distinctly, in front of the cervix. The uterine sound passed in two and one-half inches, and showed the uterus to be pressed backward in the hollow of the sacrum, with much impaired mobility. Diagnosis: "Broad ligament cyst, with very broad and close attachment to right side of the uterus, and extensive parietal and intestinal adhesions in the abdomen." At the operation the cyst was tapped and emptied, and the capsule was then removed in parts with much difficulty, owing to the extreme thinness of the cyst-wall. The short pedicle left included the cut end of the right Fallopian tube. On examination, subsequently, the parts removed were found to consist of an extremely thin-walled multilocular cyst, partly encapsulated in loose connective tissue, and having an enlarged cystic ovary closely adherent to its base. The patient had slight elevation of temperature during the first three or four days after the operation. The sutures were removed on the tenth day, and she left the hospital on the twentieth day. The details of the operation leave no doubt as to the truly extra-peritoneal nature of the cyst, inasmuch as all attempts made to open into the general peritoneal cavity, either by passing the hand upward over the upper margin of the tumor, or by endeavoring to effect an opening through the base of the cyst into Douglas' pouch, failed entirely in effecting their object. When attempting the former procedure, the operator, Mr. Thornton, came upon the cæcum and vermiform appendix completely enclosed in loose vascular connective tissue, and closely applied to the cyst-wall. This condition of things was evidently due to the adhesive inflammatory action set up in its immediate neighborhood by the rapidly growing cyst. Regarding the mode of development of the tumor the following explanation is given: the cystic disease, commencing in the outer end of the ovary, probably gave rise to the formation of a true ovarian cyst, lying at first encapsulated in the cellular tissue between the layers of the broad ligament. In the subsequent course of its growth this cyst, distending the layers of the broad ligament, continued to develop in the direction of the least resistance—viz.: more or less directly outward—until, having reached the seat of reflection of the parietal peritoneum, it gradually opened up the layer of subperitoneal cellular tissue which lies beneath the transversalis fascia lining the abdominal wall.

On the Simultaneous Employment of Calomel and Iodide of Potassium in Diseases of the Eye.—The following are the conclusions drawn by Dr. Schlaefke in a paper with the above title published in the *Archiv für Ophthalmologie:* 1. Where a patient is taking iodide of potassium internally, the local application of calomel to the eyes excites an acute inflammation. This fact was recognized in the past, but has been forgotten. 2. Iodide of potassium, when taken internally, is rapidly disseminated through the organism; it appears rapidly in the different secretions, where its presence can be detected at the end of a few minutes. 3. When the iodide is given in doses of six grains twice a day, it is always found in considerable quantity in the tears. 4. Although calomel is only very slightly soluble in water, it is ten times more soluble in a solution containing 0.75 parts per 100 of chloride of sodium. 5. When dusted on the conjunctiva, calomel is readily dissolved, and exercises a chemical action. 6. If it is thus employed while the patient is taking iodide of potassium, the iodide and biniodide of mercury are found in the tears, and these caustic substances excite inflammation. Hence, it follows that calomel should not be applied topically to the eyes while the patient is taking iodide of potassium.—*La France médicale*, September 4th.

Cancer of the Spleen and Stomach in a Child.—This case was observed at the Strasburg clinic for diseases of children, and Dr. Scheffer, who reports it, expresses an opinion that it is unique. It certainly illustrates the difficulties attending the differential diagnosis of primary gastric cancer from a similar splenic affection. The patient was fourteen years old, and on admission gave a history of nine weeks' previous illness, with pains in the left side. Upon examination an abdominal tumor was found in the left hypochondriac region. Its surface appeared smooth, and the spontaneous painfulness became increased on pressure. There was loss of appetite and vomiting. The vomited matter showed no traces of blood or other abnormal admixture until three hours before the patient's death, when considerable hæmatemesis occurred. During the course of the illness vomiting took place only three times. There was rapid and intense emaciation, with marked cachexia. Symptoms of dyspnœa several days before death. Some pleurisy on left side. Increase in the proportion of leucocytes. Febrile movement of an irregularly recurrent type, and a pulse-rate of 124 to 148. The disease reached a fatal issue after about three and a half months. The diagnosis of splenic cancer was made by the method of exclusion, and the neoplasm was thought to be primary in the spleen. At the autopsy, made by Prof. v. Recklinghausen, an ulcerating encephaloid carcinoma of the fundus ventriculi, with perforation into the spleen, was discovered. The fundus of the stomach was the seat of a large, rounded cancerous ulcer leading into a cavity in the spleen. There were numerous adhesions between the different organs in the neighborhood of the new-growth. The author believes that the secondary affection of the spleen, as revealed by the autopsy, occurred by a growth of the tumor in a directly continuous sense, and not by metastatic transmission through the lymphatic channels. He also calls attention to the fact that the gastric symptoms may, as in the present instance, be so insignificant, as compared with other morbid manifestations, that the diagnosis of cancer of the stomach is made practically impossible.—*Jahrb. für Kinderheilkunde*, September 2, 1880.

The Treatment of Uræmia in Children by Pilocarpine.—From the study of eleven cases, all treated by muriate of pilocarpine, Dr. Praetorius, of Mayence, arrives at the following conclusions: the action of the alkaloid of jaborandi on children may be recognized by active carotid pulsation, reddening of the face, and profuse perspiration, which begins on the forehead, upper lip, and chin, and gradually extends over the whole body. These symptoms appear about three to five minutes after hypodermic administration of the drug. Accompanying the diaphoresis a profuse salivary secretion is observable. In infants the sialagogue action is the more reliable of the two. The temperature is affected only in so far as the evaporation from the sweating cutaneous surface produces a slight secondary lowering. The single dose of the drug is $\frac{1}{32}$ to $\frac{1}{3}$ of a grain (0.002–0.02). The children, as a rule, complain of severe nausea, and vomiting is frequent. Conditions of slight collapse are sometimes noticeable. The following *résumé* of inferences is appended to the paper:

1. The treatment of uræmia by hypodermic use of pilocarpine gives satisfactory results. It appears advisable to resort to this plan of treatment as soon as headache, an irregular pulse, and vomiting point to the probability of renal complications.

2. The contraindications for its employment are: the presence of grave complications, abnormal weakness, collapse, or general cutaneous dropsy.

3. It appears that in "glomerular" nephritis pilocarpine fails to produce a beneficial effect. But as this variety of Bright's disease cannot be differentiated from other forms by our present methods of examination, this condition cannot, of course, be classed with the contraindications.

4. In addition to the diaphoretic action of the muriate of pilocarpine, a direct influence on the renal secretion appears to exist.—*Jahrb. für Kinderheilkunde*, September 2, 1880.

THE STRUCTURE OF THE SUDORIPAROUS GLANDS.—According to Ranvier (*Gaz. de Paris*, 3, 1880), who has reinvestigated the histology of the sweat-glands, their excretory ducts have a double or triple lining of squamous epithelial cells. The cells of the innermost layer are furnished with a so-called cuticula. The secreting epithelia form only a single layer of lining corpuscles, and lack this cuticula, a fact which Heynold has already pointed out. The cells of the glandular portion show granular striæ resembling those of the convoluted renal tubules. Fat molecules normally occur in the cells of the sweat-glands. Alcohol dissolves them, and osmic acid colors them black. The sudoriparous epithelia lack separate membranes, but their free extremities sometimes show a border to which droplets of a colloid substance are attached. The lumen of the glands is continued between the cells, and the minute channels thus formed proceed up to the membrana propria. There is a subepithelial muscular layer, the smooth fibres of which are separated from one another. The protoplasm and nucleus of these elements occupy that side which is directed toward the lumen.

The sudoriparous glands are known to develop from the stratum mucosum of the epidermis, which sends down into the corium epithelial offshoots. By simple differentiation Ranvier believes that the most external of these cells become muscular fibres. In other words, they are said to be derived from the ectoderm. The glandular lumen is not formed by fusion of the central cells of the epithelial process, but by the appearance of the cuticula. The lumen is first seen somewhat above the base of the epithelial pegs, and begins to extend in a direction toward the epidermis, leaving the secreting portion of the gland below it. Later, of course, it reaches this part. —*Schmidt's Jahrb.*, September 27, 1880, vol. clxxxvii.

INSOLATION AT ALGIERS.—Dr. Barbier, of Algiers, has recently studied the subject of sunstroke at Algiers, and communicates his opinions to the *Courrier médical*, September 11, 1880. He believes that insolation is not necessarily the result of direct exposure to the sun, but that it is essentially "*une affaire de thermomètre*." The insolation of hot climates resembles the heat-stroke of veterinarians, viz., "sudden intense congestion of the lungs, intestines, or brain during work." The symptoms, as observed by the writer, were: sudden invasion, the patient being prostrated, stupefied, with blanched face, feeble pulse, slow respiration, and cold, moist skin. Apparently little suffering and complaints of headache only. The attacks often prove rapidly fatal. Sometimes there are pronounced cerebral manifestations, such as acute delirium. Thus, the author has seen two suicides committed after sunstroke. The best curative results have been obtained by Barbier, with the tincture of aconite in daily doses of ten to thirty drops in orange-flower syrup. The action of the drug he finds to be diaphoretic and diuretic.

THE HISTOLOGY OF THE VULVO-VAGINAL GLANDS.—Although the naked-eye appearances of the glands of Bartholin have been adequately described by Huguier (*Mémoire sur les appareils sécréteurs des organes génitaux externes de la femme et chez les animaux. Ann. d. sc. nat.*, vol. xiii., April, 1850), and although Langerhans (*Virchow's Archiv*, vol. lxi., p. 208, 1874), has investigated their histology, yet there were certain points left undetermined. De Sinéty has recently completed a minute research into the structural conditions of these glandular bodies. A communication embodying the results of this examination was read at the *Société de biologie.* He finds that the gland is not enclosed in a distinct capsule, as had been hitherto supposed, but that it is represented by a diffuse collection of small glandular masses, disseminated without regularity and often separated by varying amounts of connective tissue and striated muscular fibres. The secretory lobules have a lining of goblet-shaped epithelium, resembling that found by the author in the cervix uteri. This would explain the similarity of the products of secretion of these two regions. The secreting vesicles (lobules, acini) empty with a constricted portion into sinuses lined with cuboidal epithelium. From these sinuses start the excretory ducts, rather narrow canals, lined with a single stratum of cylindrical epithelia. The common excretory duct shows several epithelial layers, and the cells approach the squamous type as the outlet is reached. This duct throughout its entire extent, almost to its vulvar orifice, shows additional glandules, which open directly into it. These accessory glandular collections are rich in nerves and have an abundant vascularization. The connective tissue of the vulvo-vaginal glands contains many smooth muscle-fibres principally disposed around the excretory canals. Striped muscular elements also form a thick layer both within the gland and outside of it. The author thinks that the existence of acini opening directly into the common duct may account for the formation of certain vulvo-vaginal fistules, with multiple intercommunicating orifices, sometimes observed in inflammations of the gland. He also believes that deep cysts of the inferior third of the vagina, may be developed at the expense of one or more of these disseminated secondary glands.—*Gazette obstétricale*, September 20, 1880.

A CASE OF GANGRENE OF THE UTERUS FOLLOWING OPERATIVE DELIVERY.—Dr. Walbaum, of Gerolstein, Germany, reports the case of a rachitic primipara with contracted pelvis, in whom a protracted operative delivery was followed by gangrene of the uterus, with an ultimate cure after complete loss of the organ. The patient was twenty-six years old, and had a pelvis measuring two and a half inches in the conjugate diameter. She was first seen when pregnancy had already advanced to full term. The uterine contractions were almost entirely lacking, and the child was dead. With the greatest difficulty the fœtus was delivered piecemeal, and the maternal parts were unavoidably bruised and lacerated. The operative manipulations lasted almost eight hours. On the two days following this procedure the patient's temperature was subnormal. Then, with the development of peritonitis, it rose to 105°. About two weeks later portions of necrosed uterine tissue of penetrating fetid odor began to be discharged per vaginam. Large lumps, some of which retained the outline of the womb, continued to pass away. These discharges lasted about three weeks, the patient meanwhile suffering from hectic fever and absolute incontinentia urinæ. There was, however, no vesico-vaginal fistula. Irrigations of the genital canal with a three per cent. aqueous solution of carbolic acid were continuously employed. No internal medication. Some four weeks later the condition of the patient gradually improved. The febrile movement slowly subsided with the appearance of a less fetid and more purulent discharge. Finally the only remaining symptom was incontinence of the bladder. Vaginal exploration now revealed loss of the uterus, the impinging finger coming upon hard tissue at the vaginal termination. A minute opening was still found at the upper end of the vagina, and a sanguinolent discharge continued to occur. It was not ascertained whether or not the ovaries had also been destroyed by the morbid process. The writer thinks it a remarkable fact that the patient bore this extensive and severe disease so well, comparatively, being now able to walk long distances without other discomfort than that which is due to the persistence of the vesical incontinence.—*Allg. med. Cent. Zeit.*, September 18, 1880.

Amyloid Degeneration.—The pathogeny of this morbid process has been made the subject of recent extensive investigations by Prof. Eberth, of Zurich (*Virchow's Archiv*, vol. lxxx., p. 138). The most important result of his investigations has been to show that this infiltration does not, as was generally held to be the case, affect the most heterogeneous histological elements, but is confined to the tissues belonging to the connective-substance group. Thus, the glandular epithelia, muscle-cells, etc., are not invaded by the amyloid material. Wherever and whenever the parenchyma appeared to participate in the change, it was ascertained to have merely undergone simple atrophy, from the pressure of the encroaching amyloid masses deposited in the blood-vessels or connective tissue. The true parenchyma of the affected organs is never destroyed by secondary amyloid infiltration or degeneration of its constituent elements. The morbid process originates in the capillary adventitia, the basement substance of connective tissue, the stroma of the liver, the membranes of the renal tubules, the internal perimysium of muscles, in the reticulated tissue of the lymphatic glands and the spleen, and the tissues corresponding to these structures.—*Centralblatt f. Chir.*, September 18, 1880.

A New Method of Operation for Ranula.—Dr. Krabbel (*Centralblatt f. Chirurgie*, No. 37, 1880) reports the successful operation of a large sublingual cyst by a method not hitherto described. It is well known that, apart from complete extirpation, the ordinary methods, such as puncture, the injection of irritant fluids, partial excision, etc., by no means always result in a complete cure. Krabbel recently had occasion to observe a large ranula, in which previous remedial measures had been unsuccessful. He adopted a plan of operative procedure which was suggested to him by a consideration of Volkmann's method of radical operation for hydrocele. Accordingly, the sac of the cyst, which formed an externally visible prominence, was exposed by an incision from without, and an oval piece of its wall excised. The cyst-wall was now united by silk sutures with the integument; then a second piece was incised from within, and the walls similarly united with the buccal mucous membrane. A drainage-tube was inserted, and carbolic irrigation practised. All the dressings were antiseptic. Eight days later the drainage-tube was removed, and the wound soon closed by granulation, the collapsed cyst-walls becoming united by adhesive inflammation. The external cicatrix was quite inconspicuous, and internally there only remained a little hardening to indicate the site of the former cyst.—*Allg. med. Cent. Zeit.*, September 22, 1880.

Milk Diet in Heart Diseases.—Prof. Potain concludes a somewhat lengthy paper on this subject as follows: The "*régime lacté*" is particularly efficacious in secondary cardiac disease, that is, in simple hypertrophy or dilatation of renal or gastric origin. In one case the milk diet favorably alters the condition of the kidneys, and in the other the gastric state. But in order to give these organs the needed repose, it appears essential to make the milk diet absolute and to prolong it for a greater or less length of time. A good action of this regimen is also observable in those cases of simple reflex palpitation, which depend upon gastric disturbance. In dropsy accompanying secondary renal lesions, the diuretic action of milk may act advantageously. This exclusive milk diet can, however, be persisted in only when the system readily tolerates it.—*La Tribune médicale*, September 19, 1880.

Subungual Sarcoma of the Fingers.—Dr. P. Kraske reports a case of this kind, which was observed at the clinic of Prof. Volkmann. A woman, forty-two years old, came to the clinic, stating that the nail of the middle finger of her left hand had been the seat of painful sensations for about twelve years. She further said that four years before that time it had been severely bruised. The substance of the nail had been scraped away above the spot of greatest tenderness, but this and other measures had afforded her only temporary relief. About the central part of the nail a blue spot was seen to shine through from the matrix. On pressure this proved exquisitely painful. A subungual tumor was diagnosticated, and the tip of the finger removed. The wound healed kindly, and the patient was discharged after a few days.

A close examination of the tip, after ablation of the nail, showed a little hard nodule, which extended down to the bone, was inclosed in a fibrous capsule, and had, on section, a grayish white appearance. This little tumor was found to belong to the group of neoplasms, which Kolaczek (*Deutsche Zeitschrift für Chirurgie*, vol. ix.) has described as angiosarcomata, and which have been variously called cancer, cylindroma, siphonoma, tubular cartilaginous tumors, etc. This author, it will be remembered, found the following to be characteristic of such growths: a reticulated arrangement of cellular groups, sometimes enclosing vessels, the epithelioid form of the cells, and an incipient hyaline degeneration. In his *Beiträge zur Chirurgie*, Prof. Volkmann has called attention to the subungual origin of such malignant growths, and it was a knowledge of his previously described cases that led to the early operation in this instance. Volkmann's former cases were all of an excessively malignant type, and proved rapidly fatal in spite of repeated operations.—*Centralbl. für Chir.*, September 18, 1880.

The Medical Record:

A Weekly Journal of Medicine and Surgery.

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, December 18, 1880.

THE INSANE ASYLUM INVESTIGATION.

The work of the Senate Asylum Committee in this city ended on the 9th inst. In our last issue we gave the principal facts testified before it, and not very much of importance was contributed after that report. A great deal of attention was excited by the evidence given, and a large space was devoted to it in the daily papers. One of the most important objects desired by the reformers, therefore—that of enlightening the public as to the facts in the case—was accomplished.

Testimony was given by more or less expert witnesses on both sides of the question. This testimony furnished very little that was really new to those acquainted with the facts of the controversy. The old charges were reasserted, and were for the most part sustained. All that can possibly be claimed by the opponents of the reform movement is that they showed the fact of a considerable improvement in the New York and Kings County Asylums during the past two years.

On the other hand, the facts of overcrowding, poor diet, poor attendance, insufficient employment, political influences, etc., were very clearly demonstrated.

There were some special controversies developed during the investigation, which made the meetings more lively, but did not increase their value. The committee concluded their work by a tour among the asylums on the islands. It should be said of its members that they seem to be investigating the subject assigned them with intelligence and impartiality. If this is the case, the evidence collected during their two weeks' stay in this city can hardly fail to show them the very great need of reforms in asylum management.

And we beg to suggest to the committee that such reforms, speaking generally, should be in the following directions:

First.—The separation of the acute and chronic insane.

Second.—Making the asylums for the acute insane more, in spirit and management, like ordinary general hospitals.

Third.—Severing politics from the medical or executive management of the asylums.

Fourth.—Establishing a lunacy commission which shall secure a thorough central state supervision and control, and which shall be the medium of ensuring protection to the rights of the insane, as well as of keeping the public clearly informed as to the condition of its unfortunate wards.

If any radical reform is undertaken, it must be in one or more of the above directions. It is scarcely possible that the committee will not see the necessity of some attempts at improving the present status of affairs. The cry of the superintendents and office-holding politicians, that all is as well as it can be under the circumstances, will not answer; it will not satisfy the demands of intelligent citizens.

PRIMARY CANCER OF THE LUNGS.

At the recent meeting of the New York Pathological Society, as will be seen from our report elsewhere, a very interesting, rare, and instructive specimen was presented of primary infiltrating cancer of the lung. The gross appearances, which resembled pneumonic tissue in the stage of gray hepatization, were quite satisfactorily exhibited. The patient's clinical history, as communicated by Dr. Ripley, in whose service at the St. Francis Hospital the case came under observation, showed anew the difficulties attending the diagnosis of this uncommon affection. Doubtless the discovery of a circumscribed area of dulness or flatness in the infraclavicular region of one side would strengthen an already existing suspicion of pulmonary neoplasm. But in the absence of other pronounced symptoms, both local and constitutional, this *per se* would be clearly insufficient to establish a legitimate diagnosis. The rapid supervention of sanguinolent pleuritic effusion was likewise inadequate to fully confirm even a rising conviction of the presence of malignant pulmonary deposit. Nor would the absence of bulging at the intercostal spaces furnish any additional clue to the existence of such disease.

It appears, therefore, that in its clinical aspects the case before us only corroborates previous experience, showing that pathognomonic symptoms of pulmonary cancer do not exist, or, at all events, are not yet known to us. Thus, while it may happen that a chain of suspicious morbid manifestations may point to the probability of cancer, the fact remains that positive evidence of its existence is, as a rule, obtained only by post-mortem examinations.

In the present instance, the pathological report of

Dr. Wendt would make it appear probable that the disease started in the upper lobe of the left lung and then spread to the other lobes, and, finally, also invaded the entire right lung. In his remarks upon the case Dr. Wendt called attention to the probability of extension along the lymphatic channels, as demonstrated by the presence of a subpleural network of lymph-vessels containing epithelial corpuscles. Whether or not the endothelial lining of these vessels remained intact was not stated, though this would appear to be a point of great interest. This lymphatic transmission was also alluded to in the light of affording a possible explanation of the extreme rapidity of the cancerous invasion. Finally, it was pointed out that, apart from other things, the presence in both kidneys of miliary carcinomatous deposits constituted the case an exceptional one.

In glancing over the literature of this subject, we are at once struck with the paucity of well-observed cases of primary cancer of the lungs. In 1878, Reinhard (*Arch. für Heilk.*, xix., p. 369) published a statistical report, embracing the record of only twenty-eight cases, collected from various sources. In all these cases of primary cancer only one lung was affected, eighteen times the right lung, and nine times the left one. Moreover, the bronchial glands were generally the seats of cancerous deposits. As a rule, extension took place in the direction of the bronchial tubules, or along the vascular sheaths. Symptoms of pathognomonic importance were not ascertained. In suspicous cases, however, it was thought that enlarged supraclavicular glands might become characteristic.

One of the most perfectly observed cases on record was made the subject of a separate thesis by Dr. Schottelius, first assistant to Professor Rindfleisch. In this case the participation of the lymphatic vessels was so conspicuous that the pathological condition of the lungs was denoted by a special name, viz., "lymphangitis carcinomatodes." It would appear that Recklinghausen was the first to call attention to the plugging up of lymphatic vessels with cancerous corpuscles. But his investigations were made in connection with cutaneous epithelioma. Cornil (*Gaz. méd. de Paris*, 1877, No. xii.) also described a case of cancerous implication of the lungs, due to transmission along the lymph-channels. From the observations of Hanot (*Arch. gen. de méd.*, 1877), Rabasté (*Thèse de Paris*, No. 295), Potain (*Gaz. des hôp.*, No. 45, 1877), Darolles (*Thèse de Paris*, No. 340), and others, no positive conclusions as to the frequency of this mode of extension can be drawn. But the fact remains that this is one of the ways in which cancer of the lungs spreads, and the case which suggested these remarks would make it appear probable that when the lymphatics are thus involved the extension of the neoplasm is a very rapid one.

The detection of cancer of the lungs during life it seems, therefore, is always difficult, and often impossible. Nor does it appear that its recognition could be regarded as more than a triumph of scientific diagnosis, for our chances of successful treatment would not be likely to be enhanced by a knowledge of its presence. Nevertheless, the pathological interest in cancerous neoplasms of the lungs will continue to exist despite the impotency of our therapy to effect more than the palliative improvement of existing symptoms.

SHALL WE HAVE A SANITARY SUNDAY?

It has always been the purpose of the Record to encourage in every way the development of sanitary science. It has been recognized from the first that prevention is to form a large and essential part of the medicine of the future. We shall not be misunderstood, therefore, if we at times protest against some of the exaggerations into which those affected too deeply with the sentiment of *sanitas sanitatum* occasionally run. Such exaggerations inevitably lead to a reaction, which *Punch* has recently given expression to in one of his cleverest lyrics:

> "*Sanitas sanitatum*
> Is all very fine,
> But my *ultimatum*
> Is this—I must dine."

Our esteemed contemporary, the *New York Times*, has recently had a touch of the hygienic afflatus, and argues very ably for a "sanitary Sunday." It advises that persons, having perhaps devoted an hour or two to religious exercises or moral reflections, spend the rest of the day in getting themselves as healthy as possible. Sunday, it is said, is the workingman's day for bringing back to a normal equilibrium the functions perturbed by his week's work.

Now, it will probably surprise the sanitarian to learn that health can be greatly promoted by devoting only one day in seven to its pursuit, for it has been generally taught heretofore that the only way to keep in good physical condition is to adopt a well-ordered life all the time. And the tendency of a knowledge that there is a day whose special function is rejuvenation would be, we think, to furnish to it the conditions requiring rejuvenation. Among a very large class, the Saturday night debauch would be thought a legitimate initiation of the sanitary Sunday, for the children of darkness are still in a decided majority, and the desire to lead a sanitary life is a very slight incentive for them to lead a moral one.

In England, Professor Tyndall has been advocating sanitary Sundays with that same pleasing eloquence which some time ago gained for him, in a few weeks, a popular reputation as a great authority on all the arts of disease-germs. But in England, if we may believe reports, the workingmen, when left to the impulses of their "humanity," generally get drunk Saturday night and stay so until Monday.

We do not believe that workingmen, or even people of higher classes, whether in England or this country, can be made to appreciate the beautiful utility of a sanitary Sunday. When released from work, the tendency is, as a rule, not to hygiene, but to pleasure; not to oxygen, but to beer. Societies for ethical culture may eloquently demonstrate the sweet reasonableness of remaining in a sober and sanitary condition; but neither sanitary precepts nor a dilettante religion can prevent the people, if otherwise unchecked, from turning the professed "sanitary Sundays" into grand festal days—which are not hygienic institutions.

We do not wish to be understood as advocating the Puritan Sabbath, and it is no part of our work to discuss theological points. We simply do not believe that it would benefit the health of the people to have the word "sanitary," or the idea of sanitation, so prominently associated with Sunday. If a man has those motives of conduct which cause him to lead a correct life, he will be likely to lead a sanitary one. Hence, the time spent in inculcating those motives is, indirectly, health-giving. Health, on the other hand, though intimately connected with right conduct, is very far from insuring it; and the desire to be healthy, we repeat, has very little power among those who would take the most advantage of a "sanitary Sunday." Let there be healthy relaxation, and even innocent recreation, if need be, on that day. But we would have something higher than "sanitation" associated closely with it. We have one national wash-day on Monday; there is no need of two.

PROGRESS OF DIPHTHERIA AND SCARLATINA.

We took occasion, in a previous number of the Record, to call attention to the prevalence of contagious diseases, and notably of scarlatina, diphtheria, and small-pox, in this city. Nor have these diseases, since we noticed their increase, shown any tendency to abate, either in the number of cases or in the proportion of deaths. For the week ending December 4th there were one hundred and fifty-one cases of scarlet fever, and one hundred and sixty-seven cases of diphtheria reported; while, for the succeeding week, the numbers were one hundred and eighty and one hundred and sixty-six respectively. It will thus be seen that the former disease is still spreading, while the latter maintains the high figure which had previously been attained.

In view of the great prevalence of these diseases, a special investigation was made by the health authorities, to discover whether defective hygienic conditions played any very marked part in the etiology, and the result was far from satisfactory, as tending to prove any constant relation between contagion and bad sanitary conditions. Both sanitary physicians and sanitary engineers agreed that the houses which they had especially investigated, because of their having been the seat of many cases of diphtheria, were, hygienically speaking, rather above than below the average; and in many of them the arrangements were such that they could not be improved upon with our present knowledge. It was possible that unsanitary surroundings might have tended to increase the severity of the disease, when it did occur; but even this fact could not be said to have been demonstrated.

Every physician has met, in his practice, with many cases in which foul gases were the only assignable cause of contagious diseases. The emanations from decomposing animal and vegetable matter have been regarded, at various times, as the agents in producing many disturbances in the human economy. Gradually, as research has been carried on more scientifically and rigorously, this theory of their origination has become more and more circumscribed, until to-day it is only believed to apply to diphtheria, typhus, and, perhaps, typhoid fever. We shall not attempt to discuss this very important and much-argued subject here, but, until the question is decided, beyond the shadow of a doubt, the duty of the physician in the matter is clearly to take no risks. He should inquire into and, as far as possible, make a personal investigation of the sanitary condition of the premises. This should include the dryness of the cellar, the purity of the water-supply, the appliances for the prevention of the escape of sewer-gas, and the inoffensiveness of the privies and water-closets. Granting that sewer-gases alone are not capable of producing the disease, still it is quite possible that they should be the means of conveying the germs or *materies morbi* in some form or other. But, on the other hand, whether he has found the hygienic conditions as they ought to be or not, the physician should not rest content in the belief that here is the sole cause of trouble, or that the air is the vehicle of contagion. He should endeavor to discover, by a vigorous search, where the disease came from, and in some cases the knowledge thus gained will be of advantage in preventing the same cause from operating again. Isolation and disinfection should be practised as thoroughly and completely as circumstances will permit; and where, as in scarlatina, the desquamated skin is supposed to be the carrier of the disease, it adds not only to the comfort of the patient, but also to the safety of those around, to anoint the patient with some oily material, which shall render the scales heavier and prevent them from flying about.

We would continue to call attention to the responsibility of the physician in regard to vaccination. During the week ending December 11th seven persons died of small-pox in this city, all of whom had either never been vaccinated, or had not been for a number of years. When it is remembered that variola depends solely upon contagion, and that the means of prevention are at our command, simple and almost entirely free from danger, no one can hold a physician quite free from blame in the family of whose patients a case of this disease occurs.

DIPHTHERIA FROM THE TRACHEOTOMY-TUBE.

We are again called upon to record the death, from diphtheria, of a member of our profession, who contracted the disease during the performance of tracheotomy upon a diphtheritic subject.

Dr. Sandford B. Hunt, of Greenpoint, N. Y., was the victim. The simple, but suggestive story of his attack is that a tracheotomy-tube, which he had been using upon his patient, became choked up, when he cleared it by placing it to his mouth and blowing through it. There is so much of melancholy regret about such occurrences that it is liable to swallow up every other feeling. But there are other aspects in which to view the question. It is high time that we stop to consider the lesson which the present case affords. Although we are taught almost from our medical cradle never to be backward in "hazarding life in the performance of professional duty," it sometimes behooves the physician to consider whether the end aimed at always justifies the means. We contend that it does not, in a desperate case of diphtheria, where the positive chances of infection from such a cause as stated are taken into account. It is not the duty of a medical man to jeopardize his valuable life against any such odds. The motive is a laudable one, which, on the spur of an emergency, would make the surgeon forget everything but his patient, but in being actuated by such a motive, he is not expected to be foolhardy. It must be admitted that the prompt clearing of a tracheotomy-tube is very important, but there should be other ways of doing it than by the direct application of the surgeon's mouth. A simple apparatus for the purpose should be as indispensable to the surgeon in such cases of tracheotomy as the tube itself. In these days of surgical invention, it seems strange that no suitable instrument for such a purpose has been made. The necessity for it is emphasized every time a new death occurs from blowing into a poisoned tracheotomy-tube. The mourning for Dr. Hunt is invested with a peculiar sadness in that his death might have been prevented.

◆

☞ Bacteria in the Air.—The average number of bacteria in the air, according to Dr. Miguel, is about 200 per cubic metre. This number is diminished in winter, increases in spring, reaches its height in summer and the first part of autumn, and rapidly diminishes during frost. There are, however, in addition, various paroxysmal variations in the number of atmospheric bacteria. And we are told that every increase in the bacteria of the air is followed eight days later by an increase in the deaths from contagious and epidemic diseases.

Reviews and Notices of Books.

Practical Lithotomy and Lithotrity; or, an Inquiry into the best Modes of Removing Stone from the Bladder. By Sir Henry Thompson, F.R.C.S. 8vo. Philadelphia: Presley Blakiston.

Certainly no man now living is better able to speak, and speak with authority, of the subject of which this work treats than its distinguished author; not only from his very extended experience, but also from the eminently scientific character of his mind—the ability to weigh facts, or alleged facts, and to decide as to their value, both absolute and relative. The book, as its name indicates, is a practical one; no time is expended and no space is taken up with the consideration of the causes, symptoms, diagnosis, etc., except as, incidentally, mention is made of them in connection with the operative procedures which constitute the author's theme. After defining the terms lithotomy and lithotrity, the author devotes the first part of the work to the consideration of the former, bringing all the operations under two heads: those by which the bladder is reached through the perineum, and that by which it is reached above the pubes; and the first class he again divides into lateral and central. In taking up the anatomy of the parts concerned, the outlet of the male pelvis is compared neither to a triangle nor to a lozenge, but to the conventional ace of hearts, with the apex upward. After the usual dissections have been described, the reader is reminded of the direction in which he can cut with the greatest impunity, and of the parts particularly to be avoided.

Chapter II. begins the consideration of lateral lithotomy, with a description of the instruments, assistants, and other aids essential to the proper performance of the operation; and among the former, the air-tampon, consisting of an inflatable rubber bag attached to the drainage-tube, by the expansion of which an even pressure is obtained for the arrest of any hemorrhage, after the operation, beyond the reach of the ligature. The question of the relative usefulness of the scalpel, the probe-pointed knife, and the gorget is discussed, the preference being given to the former on the score of ease and simplicity, unless in exceptional circumstances. The position of the patient, the incisions, and the other steps of the operation are next described in the usual manner, especial stress being laid on the necessity of slow and cautious action in withdrawing the forceps, the importance of which "it is quite impossible to overestimate." In the after-treatment, the author does not give opium as a matter of routine, but only if the symptoms seem to call for it; and the question of the use of a tube is left open.

In Chapter III. the central operations are described, including the bilateral, medio-bilateral, median, and recto-vesical. The combination of lithotomy with lithotrity is one which the author thinks will not likely be necessary, since lithotrity has been so much improved. The subsequent chapter describes the supra-pubic operation.

Chapter V. takes up the causes of death following lithotomy, and adults are considered separately from children. Those affecting adults are divided into those arising from error or accident in the performance of the operation, and those arising from other circumstances, particularly the constitution of the patient. Infiltration of urine is shown to be by no means the bugbear commonly supposed, the bad results generally attributed to it being, in the author's opinion, due to "violence in opening up the internal part of the wound, and laceration of the tissues there." Attention is again called to the importance of slowly and gradually dilating the neck of the bladder and the incisions. In children, the greatest number of deaths are found to be caused by peritonitis and exhaustion.

Chapter VI. discusses the difficulties and dangers met with in lithotomy. The former are considered under three heads: those peculiar to the patient's age, those peculiar to the subject, and those peculiar to the stone, and under the last heading the processes of breaking the stone are described. The non-fatal accidents are then discussed, as well as the manner in which they may be avoided or remedied.

But probably the most interesting portion of this part of the work is Chapter VII., on the results of lithotomy. The average of the past for all cases would seem to be about one death in every eight and a half cases. But, below the age of sixteen, the deaths are one in fifteen and a half, above that, one in five. But for the future, since the great improvement in lithotrity, the figures will have to be changed; and, as the result of his experience in five hundred carefully recorded cases, the details of which are given in a copious appendix, the author finds that he has lost one in every two and three-quarter cases by lithotomy, and one in rather more than thirteen by lithotrity. The worst cases, especially those of large stones, were lithotomized.

However much we may admire the clearness, fairness, erudition, and moderation of the first part of the work, we are more interested in the second—that devoted to lithotrity. The bearings of lithotomy are generally understood and well defined, except in its relation to lithotrity; but the latter subject opens up a field which may still be described as new. After a brief historical survey of the growth of the operation and of preliminary treatment, in which he prefers as a demulcent the decoction of the unground stems of *triticum repens*, the author, in Chapter IX., defines the objects of lithotrity and the principles on which instruments should be constructed. And, on what seem to be good grounds, he thinks his own instrument fulfils the indications most fully.

After this introduction, the steps of the operation are described in Chapter X.—the best position of the patient and of the operator; the method of introducing the instrument, of seizing and crushing the stone, and of removing the fragments and débris. Injection of the bladder is not considered necessary, and slow, slight, and deliberate movements of the instrument are again impressed on the reader.

Chapter XI. is on lithotrity at a single sitting, as Sir Henry Thompson prefers to call litholapaxy. While giving due credit to Prof. Bigelow (of *Harvard* (?), United States), he thinks that experience was gradually tending in that direction, especially since the introduction of the aspirator of Clover. He objects to Bigelow's instruments as unnecessarily large and clumsy for at least three-fourths of the cases; and gives the details of his own thirty-five cases, all of which have been successful.

In the complications of lithotrity, stricture of the urethra is shown to be not so formidable an obstacle as generally supposed, as it may in most cases be overcome by continuous dilatation. In estimating the results of lithotrity, in Chapter XIII., the difficulty of the study of this part of the subject is pointed out, on account of the great improvement which has taken place within late years. While not endeavoring to detract from the glory of Civiale, the author rejects his conclusions as biassed by his prejudice. A correct estimate can only be made by regarding the age of the patient and the size of the stone in each case. In considering the causes of death in his own 32 fatal cases out of 422 operated on by this method, he finds nephritis, pyelitis, and cystitis the most frequent. He concludes that the danger is in direct ratio to the size of the stone, and that for those smaller than a nut the operation is almost free from risk.

The concluding chapter, XIV., is on the choice of proceeding. This may, the author thinks, in most cases, be decided by the age of the patient, but that, before any decision is reached, the size, form, and nature of the stone should be made out. From birth to fourteen years, lithotomy is, in almost all cases, the best operation; above twenty, lithotrity is, under ordinary circumstances, to be preferred; from fourteen to twenty the choice must depend upon local conditions. In healthy adults, if the stone is of medium size or smaller, it should be crushed; if it is large, the lateral operation will generally be best. In feeble patients with no urinary disease, lithotrity is preferable; in cases complicated with obstinate stricture of the urethra, lithotomy is more advisable. In view of the increased danger arising from the fact of the stone being large, the author draws the important practical conclusion that it should be recognized as early as possible.

Viewed as a whole, the work must be regarded as eminently scientific. Facts are closely scrutinized and clearly arranged, and deductions are logical and free from prejudice. However much future investigation and experience may alter or overthrow portions of it, up to the present time it comprises the results of wide experience in a condensed and tangible form.

THE MEDICAL RECORD VISITING LIST OR PHYSICIAN'S DIARY FOR 1881. New York: Wm. Wood & Co.

THE RECORD Visiting List, besides enabling the physician to record in easily accessible form his daily and weekly business, contains many facts which will be found useful to have on hand at short notice. It is printed on strong paper, with gilt edges, and is bound in durable leather. It is furnished with a pocket and pencil and with a scale of sounds, both according to the French and English methods. It is not so small as to render the use of unintelligible hieroglyphics necessary, nor yet so large but that it can be conveniently carried in the pocket.

THE PHYSICIAN'S VISITING LIST FOR 1881. Philadelphia: Lindsay & Blakiston.

THE fact that the issue before us is the thirteenth annual edition is *prima facie* evidence that this visiting list has met and maintained the confidence of the profession. Nor need we seek far in order to discover the reasons of its popularity; it is neat, compact, and durable, contains a great deal of useful information in a readily accessible form, and, with a little ingenuity on the part of its owner, it can be made to serve the purposes of a day-book, journal, and cash-book in one. At the end of the year, whether he see twenty-five or fifty patients weekly, the physician can see, almost at a glance, his annual business, as well as how the accounts of his various patients stand.

Reports of Societies.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, November 24, 1880.

DR. T. E. SATTERTHWAITE, PRESIDENT, IN THE CHAIR.

RECURRING UTERINE FIBROMA.

Dr. Post presented a fibroid tumor which had been removed by operation from the posterior lip of the cervix uteri. The patient was between thirty and forty years of age. The special interest in the case was the return of the disease. Seven years ago she entered the Woman's Hospital and a tumor was removed from the posterior lip of the cervix. Three years later the growth reappeared in the same situation, distending the vagina and completely filling the pelvis. In this condition she entered the Presbyterian Hospital. The tumor was of such enormous size that Dr. Post was unable to remove it except by preliminary disintegration by the actual cautery, and the final use of the ecraseur to the stump. She left the hospital in the course of a couple of months after. A few weeks since she sought advice for an intestinal trouble, and, among other things, stated that since the operation four years ago she had been the subject of a slight mucous and bloody discharge. On examination a tumor the size of a duck's egg was discovered attached to the original site. The operation was performed November 24th, by drawing down the uterus and including the mass in the loop of a wire ecraseur. After the main growth was removed it was necessary to take away smaller masses. A removal of the portion of the posterior lip of the cervix to which the tumor was attached was contemplated, but it was found impossible to bring down the uterus sufficiently low for the purpose. Another difficulty was the impossibility of defining the outlines of the growth, as the latter seemed to lose itself in the healthy tissue. A ragged cervix was left behind, and was touched by a forty-grain solution of chloride of zinc.

The growth was softer than formerly, but Dr. P. was inclined to think that it was non-malignant because of its slow growth.

On motion, the specimen was referred to the Microscopical Committee.

PRIMARY INFILTRATING MEDULLARY CARCINOMA OF LUNG.

Dr. Ripley presented a specimen of the above with the following history: John Hague, aged fifty-eight years, widower, laborer, born in Germany, but a resident of this city for the last thirty years, was admitted into St. Francis's Hospital October 20, 1880. His family history was exceptionally good, and he himself had always been healthy until three months ago. He was a temperate man, and had never had syphilis. Three months prior to entering the hospital he first noticed that he had a slight cough, and this had since continued, but without getting worse; the expectoration accompanying it had been simply mucus. During the two weeks preceding his admission he had complained of some pain and soreness in the sternal region, of dyspnœa on exertion, and of weakness. A physical examination of his chest was made by Dr. Haupt, the house physician, October 21st, with the following result: Marked dulness under the left clavicle, extending downward about three inches, with loss of vocal resonance over the same region, and only distant bronchial breathing heard on auscultation. No other abnormal physical signs were observed at this time, although both lungs were examined.

I first saw the patient October 29th, and observed the following changes in the physical signs: left side of chest comparatively immovable, with retraction of lower intercostal spaces in front. Vocal fremitus lost over left chest in front, increased over upper third behind, but diminished over lower two-thirds, over right lung increased posteriorly. Apex-beat of heart found at ensiform cartilage.

Percussion.—Flatness over the entire left chest in front, dulness behind. No marked changes observed on the right side.

Auscultation.—At the left apex, in front, distant, feeble, bronchial breathing; below, absence of all sounds. Posteriorly, same side, bronchial breathing loud and superficial at the apex, feeble and distant below. On the right side, posteriorly, feeble inspiration and prolonged expiration.

The peculiar grouping of the physical signs, taken in connection with the history of the ailment, made us suspect malignant disease of the lung, although the case in most respects resembled a descending pleurisy. After introducing a hypodermic needle into the left chest, both in front and behind, and obtaining at each trial a syringeful of bloody serum, we pretty much decided that it was a case of simple subacute pleurisy, and that the blood was a result of the tearing off of old adhesions.

As the respirations at this time were hurried (40 per minute), the house physician was directed to draw off a portion of the fluid, and accordingly the following day removed thirty-two ounces by aspirations. No marked relief followed. The patient died rather unexpectedly of exhaustion, November 5th, without any further physical examination having been made. The urine had, however, in the meantime, been examined, but with negative results.

The *post-mortem* examination was made twelve hours after death, by the curator, Dr. Wendt, and is detailed below.

The body was that of a powerful, muscular man, and was but slightly emaciated. The heart appeared normal, barring some incipient atheromatous deposits just above the aortic semilunar valves.

The *pericardial sac* contained a small quantity of yellowish fluid. The left parietal pericardium showed a collection of small, whitish deposits at a point corresponding to a rather firm adhesion of the sac to the lung.

The *left lung* showed adhesions of its pleural covings, especially at the anterior border of the superior lobes, where they were quite firm. The pleural cavity contained about one quart of a bloody, rather turbid fluid. On cutting the pulmonary tissue, all the lobes were found to be more or less solidified. The impression conveyed at first sight was that of a catarrhal pneumonia, or a croupous pneumonia, with incipient purulent resolution. There were between the rounded areas of grayish white solidified lung patches of hyperæmic and partially atelectatic pulmonary tissue. Numerous slate-colored or black streaks were also found throughout the parenchyma. A beautifully marked white reticulum, with polygonal meshes, was seen just beneath the pleura. On pressure, the infiltrated portions yielded a muddy fluid of creamy consistence. At the apex some breaking down had occurred.

The right lung was also infiltrated, but much less extensively, and the disease was confined almost exclusively to the lower lobes. The pleural cavity contained a few ounces of bloody serum. There were also some pleural adhesions, but they were less extensive and less resisting than those of the opposite side.

The *bronchial glands* were quite hard, enlarged, and uniformly black.

The œsophagus, stomach, and intestines appeared normal: the spleen was small and soft. The liver was healthy, though somewhat hyperæmic. Both kidneys showed slightly adherent capsules. After removal of the latter, the surface of the organ was seen to be studded with numerous whitish deposits, most of which were of miliary size. The interior of the kidney also showed these sprinklings, but in apparently less abundance.

A microscopical examination of the juice yielded on pressure of the lungs revealed the excessive presence of large polymorphous, epithelial cells, with one or more distinct nuclei. Many of these cells were in a condition of fatty degeneration. A further examination proved that the pulmonary condition was one of *primary infiltrating medullary cancer*, and that the miliary renal bodies were secondary cancerous deposits. The pulmonary alveoli were distended with the cancerous infiltration; the visceral pleura was not much thickened. The subpleural white reticulum was found to correspond to a network of lymphatics, and the black streaks were the pigmented interalveolar septa.

Dr. Wendt remarked that perhaps the case was a unique one. Apart from the great rarity of primary cancer of the lungs, the fact that in the present instance all the lobes of both lungs were infiltrated, constituted this case an exceptional one. Moreover, the extreme rapidity of the invasion, as indicated by the clinical observations, apparently left no time for a secondary affection of the bronchial glands. An additional point of interest was found in the presence of secondary miliary deposits in both kidneys. Generally the liver was the first organ to be implicated by metastatic tumors. Of course, when the disease had become so extensive as in this case, it was no longer possible to determine with accuracy the histological origin of the neoplasm. Its mode of growth was probably along the lymphatic channels, and not by simply spreading to the contiguous tissues. The existence of the subpleural reticulum of lymphatics containing epithelial bodies, justified this assumption. Ordinarily pulmonary carcinoma was found in larger or smaller nodules, although the infiltrating variety was also known to occur. The freedom of the pleura from cancerous transformation was another noticeable feature of the case. The morbid process had probably started in the apex of the left lung, where some breaking down was discovered, constituting what had been described as cancerous phthisis. Perhaps the rapidity of extension was due to transmission along the lymphatic channels.

Dr. Ripley stated that the views of Hertz that cancer of the lung had its origin in the parenchyma of the organ, appeared to be in accordance with clinical experience in the present case, viz., that the air-cells were the last to be affected. In answer to a question from Dr. Sattherthwaite he stated that there did not appear to be a doubt that the disease had commenced in the left lung. Regarding the diagnosis of such a disease, there was always great difficulty even when there was not the complication of pleuritic effusion. In fact it was the rule to make the diagnosis at the autopsy.

Dr. Satterthwaite remarked that there was a reason why the diagnosis was obscure in such cases, viz., that the deposit of cancerous material was disseminated pretty evenly throughout the extra-alveolar tissue of the lungs, in this respect resembling miliary tubercle, which, it was well known, might infiltrate the same tissue easily and extensively and, yet give rise to no special physical signs.

Dr. Lewis Smith remarked, apropos of the diagnosis in such cases, that inflammatory lung troubles in infants, when disseminated throughout the pulmonary tissue, were difficult and often impossible of detection.

Dr. Carpenter asked if there were any cancerous deposits in the pleura.

Dr. Wendt replied that the lymphatics in the subpleural spaces were filled, and exhibited to the naked eye well-marked networks. Microscopic examination subsequently showed that they contained epithelioid corpuscles similar to those in the lung-cancer.

AORTIC VALVE WITH FOUR CUSPS.

Dr. Peabody presented a specimen of aortic valve with four cusps. The fourth cusp was quite small and was interposed between the angle of junction of two others. The heart appeared perfectly normal. The anomaly in the valve was evidently congenital. The man from whom the specimen was taken died as the result of violence. The valve was found to be sufficient. In this connection Dr. Peabody called attention to an anomalous condition of the aortic valve previously presented to the Society, in which only two cusps were discovered.

Dr. Satterthwaite thought that the extra cusp was a mere accessory rudimentary organ without special function.

Dr. Peabody remarked that the cusp was so situated as to be hidden when the valve was distended.

VALUE OF THE WATER-TEST.

Dr. Ripley asked the president if he considered the water-test a satisfactory one.

Dr. Satterthwaite remarked that it was not altogether trustworthy, inasmuch as a perfectly healthy valve might fail to close with the water-test at post-mortem, while a diseased valve might often be made to close, if the heart were held in some particular position.

Dr. Ripley said that he had frequently failed in closing the valves by the water-test, when he was quite certain that there had been no valvular murmurs during life.

THE MUCOUS MEMBRANE OF THE UTERUS DURING MENSTRUATION.

Dr. Peabody exhibited the uterus with ovaries attached, and removed from the body of a woman aged twenty-five years, who died the day previously from the effects of very extensive burns. She was in perfect health at the time of her death. At the autopsy there were found no lesions of the viscera, except congestion of the brain, lungs, and kidneys. The interest in the case centred in the condition of the uterine mucous membrane, which was uniformly thickened throughout the body of the organ. This thickness was equal to six or eight millimeters. Dr. Peabody had not met with a similar condition before, in an apparently healthy uterus, but Prof. Dalton, who had seen the specimen, had informed him that it was a normal condition of the uterine mucous membrane preceding menstruation. The correctness of this view was proven by the existence of a corpus luteum, three weeks old. In the opposite ovary was found a cyst large enough to admit the tip of the thumb.

Dr. Carpenter referred in this connection to the researches of Dr. Englemann, of St. Louis, who, with Dr. Kundrat,* of Vienna, had established the facts that the mucous membrane of the uterus, during the period of maturity and functional activity, was a little over 0.04 (1.0 mm.) of an inch thick at the fundus and the anterior and posterior walls; and that during the menstrual period it was swollen from 0.118 to 0.236 of an inch (3–6 mm.) in thickness.

Dr. Tauszky referred to similar observations made by Dr. Williams, of London. He asked if there were any evidences of endometritis in the specimen.

Dr. Peabody remarked that there were no such evidences.

UTERINE MYOMATA WITHOUT SYMPTOMS.

Dr. Peabody also exhibited two uteri showing myomata in various stages of development. One was removed from a patient, aged fifty-two years, who died of apoplexy; and the other from a patient, aged fifty years, who died from an attack of acute tonsillitis while suffering from softening of the brain. In the former case no history of uterine disease could be discovered, and in the latter no complaint referring to the uterus was made by the patient during two months that she was under observation at the hospital.

AMYLOID DEGENERATION FROM CACHEXIA.

Dr. Gibney presented a specimen of dry caries of the dorsal vertebræ associated with the condition of waxy kidney. The specimen was removed February 19, 1879, from the cadaver of a boy who died the same day, and was presented to place on record a case of amyloid degeneration of the liver and kidney, which developed without a history of either syphilis or suppuration. Carious ostitis was essentially a suppurating disease. Notwithstanding this fact, however, there had been no congestion abscess, and no prolonged suppuration such as usually preceded the pathological condition of the organs mentioned. The case contained many other points of interest, and he proposed to give it in detail:

March 7, 1878.—I recorded notes of this patient, David D——, aged fourteen years, who had been an irregular attendant in the out-door department of the Hospital for the Ruptured and Crippled since October 10, 1872, on which date caries of the first, second, and third dorsal vertebræ had been diagnosticated and treatment begun therefor.

The paternal family history was tuberculous through two generations.

During the early part of his treatment he became paraplegic and was totally unable to walk for three or four months. Has been in moderately good health since his recovery from the paraplegia, but for the past two years his fingers have been growing clubbed, and now this deformity is very marked. From time to time examinations have seemed to reveal cavities in the lungs, yet the constitutional disturbance has not been sufficient to warrant such a diagnosis.

Recently, œdema of the feet and legs has appeared, and dyspnœa has accompanied this condition. Now, there is a very large abdomen, with fluctuation quite distinct, great œdema of the feet and legs, and puffiness about the face. Urine abundant in quantity, straw-colored, containing a flocculent deposit, and fifty per cent. albumen by the nitric acid and heat test, and hyaline and granular casts, probably fatty. Ophthalmoscopic examination negative.

The height of the vertebral prominence is two inches, and there is no sign of congestive abscess. Is ordered infusion digitalis, ʒ ij. t. i. d. After a few days the œdema became less, and he went about as usual. On December 7th his blood was examined microscopically, and no evidence of leucocythemia found. His liver and spleen were found on percussion to be enormously enlarged.

January 19, 1879.—Anasarca increased, and his dyspnœa became distressing. The usual diuretics and cathartics afforded temporary relief, but his symptoms finally returned, and he died after a few convulsions on the 19th of February, no coma having been present.

Dr. Janeway kindly assisted me at the autopsy, eight hours after death.

Lower half of body, including the extremities, œdematous. Abdomen greatly distended, was punctured and about three quarts of clear serum drawn off.

Liver greatly enlarged, filling the larger part of the abdominal cavity, extending on the right side up to the third rib and down to a point four and a half inches below the border of the free ribs. The lower border rounded and about two inches thick. The left lobe was also enlarged, yet its lower border was sharp. Weight four and three-quarters pounds; dark colored and very solid; surface smooth and shining, and waxy to one's touch. On section the same color was observed, and Dr. Janeway pronounced it typically amyloid. The iodine test confirmed this opinion.

Spleen enlarged, weighing nine ounces, irregularly lobulated; hard, shining, and waxy in appearance.

Kidneys.—Weight of each, eight ounces; surface smooth, but covered with small lobules; color, a clear white mottled with red at intervals. Capsules for the most part strip off readily, though at a few points adherent, tearing away the substance of the gland with it. On section, the enlargement was seen to be due to thickening of the cortex, which in some places amounted to a half-inch. This was of a homogeneous dead white color, against which the pyramids, which appeared natural, stood out in bold relief. No cysts in the cortex or pyramids. On treating the cortex with compound solution of iodine, dark mahogany striæ were brought out, showing the waxy infiltration in the walls of the tubes and vessels. This color was not changed on the addition of sulphuric acid.

Thorax.—No considerable amount of fluid in the pleural cavity. Chest explored through the diaphragm, and the examination was not fully satisfactory. The right lung, as far as could be judged by one hand, it not being removed, was normal. The left was removed, and a dense hard mass was felt at the apex, which, on section, showed fibrous induration, but no cavity or tubercle found. Very little if any extra fluid in pericardium, and the heart, though not removed, seemed about normal in size.

The *clubbed* fingers Dr. Janeway attributed to the dyspnœa.

Spine.—The whole dorsal region was removed by sawing through transverse process.

At the apex of the angle of the kyphos, on the left side, was observed a cheesy mass, through which the saw passed.

A section made through the portion of the column removed, beginning from below, gave: Bodies of the twelfth and eleventh dorsal vertebra intact, and also the inter-vertebral disk. The disk between the eleventh and tenth was represented only by the articular cartilages, the body being absent; but the bodies of the contiguous vertebræ did not face together. In the body of the tenth was a cavity at the upper two-thirds, and posteriorly encroaching upon the body of the ninth. These vertebræ were fused together at the anterior portion. The cavity was one-half inch antero posteriorly and vertically, and about one eighth laterally. The intervertebral disk between the tenth and ninth was the last one we could recognize as we passed upward until we reached the one between the third and second. The intervening bodies, *i.e.*, the ninth, eighth, seventh, sixth, fifth, fourth, and third, were fused together into one solid mass, which measured along its anterior border one and a quarter inches. The angle in the spine thus formed was a little less than 90°, the apex being at the sixth dorsal. Behind this mass and more to the right side was a cavity communicating with the spinal canal and apparently formed at the expense of the spinous processes. It would hold about ʒ iij. of fluid, and was lined by an enormously thickened dura and pachymeningeal tissue, in all about three-eighths of an inch thick.

---

* Stricker's Medizinische Jahrbücher, 1875.

The cord was a little smaller than normal, and on section presents nothing microscopic except a faintly grayish hue in anterior cornual left side. On inner side of the meninges was a well-marked false membrane to all appearance fully organized. These tissue thickenings extended from this point up and down one inch. Sections of cord at different points showed nothing microscopic.

On removing the soft parts it was seen that the pedicles of the fifth, sixth, and seventh vertebræ formed the angle of the prominence, and were here firmly fused together, the sixth and seventh being joined through nearly their whole extent. The spinous processes of these vertebræ were also fused, forming a continuous and regular arch of bony substance. There was nothing left of the fourth vertebra except the pedicles, and these were small. All that remained of the bodies of the fifth, sixth, and seventh, was a piece three-eighths by one quarter inch in size. A bridge of bone connected the fourth and fifth anteriorly, so that virtually the pedicles of the fourth, fifth, sixth, and seventh were fused together into one mass. These articular remnants between the third and fourth showed loss of synovial membrane—in fact, there seemed to have been here a true arthritis with destruction of surface.

Dr. Robinson asked if there had been any history of malaria in the case, as such might, in the absence of other causes, explain the condition of waxy kidney.

Dr. Gibney replied in the negative.

Dr. Satterthwaite asked if there had never been any previous suppuration in any portion of the body.

Dr. Gibney replied that there was no evidence of any, except that of a small cheesy mass, referred to in the history. In this connection he remarked that in most of the cases of amyloid degeneration there was a tuberculous diathesis associated with the condition of suppuration.

Dr. Ripley asked if cases of amyloid degeneration depending upon prolonged suppuration did not improve when the cause of the suppuration was removed.

Dr. Gibney replied affirmatively.

Dr. Ripley remarked that such a view militated against the existence of a tuberculous diathesis in these cases.

Dr. Gibney stated that there was no evidence that waxy degeneration disappeared entirely, as no autopsy could prove such a point. It was not unfrequently the case that young patients who had exhibited these difficulties improved until the period of puberty, or when phthisis was most apt to develop itself and then they would succumb to the latter disease.

Dr. Ripley remarked that such cases might recover from the waxy degeneration and have phthisis afterward. Several years ago he amputated the thigh of a boy for suppurating disease of the knee-joint, which was associated with waxy degeneration of the liver, spleen, and kidney. After the operation the liver and spleen decreased in size, the urine ceased to furnish casts, and to all appearances the child entirely recovered.

Dr. Wendt replied that the reduction in the size of these organs might have been due to the absorption of the fatty deposit which frequently coexisted.

Dr. Ripley said that clinically it was hard to determine whether the organs were fatty or waxy, but it seemed to be a fact that when these organs were subject to so-called waxy degeneration the patients were in very poor health, and that when these organs were reduced in size the health returned. It was also a fact that patients with large fatty livers often enjoyed very good health.

Dr. Peabody remarked that waxy degeneration was a compound condition. In the liver and spleen it was made up of a fatty and of an amyloid deposit, but in the kidneys it was associated with an extra pathological change, viz., that of chronic diffuse nephritis. Taking this view of the question it was possible to conceive how the organs might be reduced in size and yet not return to an absolutely healthy condition. At least such a supposition could be tenable regarding amyloid kidney, a disease which was considered incurable.

Dr. Ripley understood such views to be merely theoretical, as there were no means of proving that waxy kidney could not be cured. It used to be held that when a patient had Bright's disease of any considerable standing that he must die. Now it was known that the most marked evidences of Bright's disease might show themselves, and that the patient, so far as was known, got well, or at least lived for years. It might be said that this kidney disease would return, but it was hard to prove it.

Dr. Peabody remarked that waxy kidney was considered incurable, because when it had been diagnosticated before death it was always found post-mortem, notwithstanding the fact that the spleen and liver were decreased in size and that the patient had improved in health as the immediate result of arresting the suppurative discharge.

CASTS AS A SYMPTOM OF BRIGHT'S DISEASE.

Dr. Amidon presented a specimen of urinary casts, which was interesting as bearing upon the question of the prognosis in kidney disease. The specimen was obtained eighteen months ago from an engineer of a Pacific mail steamer, who was suffering at the time from symptoms of southern malarial fever. A diagnosis was made accordingly. On examining a specimen of urine under the microscope the following day Dr. Amidon was very much surprised to find casts of all varieties except the hyaline. The urine contained five per cent. of albumen and two and eight-tenths of urea. Dr. A. was so much alarmed at the condition of the urine that he made haste to modify his original diagnosis by adding thereto the grave one, of complication of acute nephritis. An unfavorable prognosis was also given. Quinine was administered hypodermically. The next day the temperature had fallen almost to the normal point, he specific gravity of the urine increased, there was no albumen, but few casts, and the urea was increased to three and eight-tenths per cent. The patient continued to improve, so that at the end of a week he was fairly convalescent. The patient at the time of making the report was in perfect health. Here, then, was a case in which all the varieties of casts save one were found in the urine, and yet the patient recovered.

Dr. Tauszky remarked that in the specimen presented he did not see any more than two varieties of fibrinous casts.

DIPHTHERIA.

Dr. Lewis Smith presented a specimen of diphtheria removed from a child one year old, who died a few days after having been attacked with the disease. The exudation was noticed upon the uvula, both tonsils, and posterior portion of the pharynx, and at the autopsy was found to extend as far downward as the bifurcation of the bronchi. The urine was albuminous, but no examination had been made for casts. He presumed that casts of the usual varieties, granular and hyaline, would have been found because of the intense congestion of the kidney that was present.

Dr. Smith, in alluding to the general characters of the disease, took occasion to remark that it was essentially constitutional from its inception.

Dr. Ripley concurred with the latter view, maintaining that the symptoms were those of special poisoning rather than of ordinary septicæmia.

Dr. Robinson remarked that the albuminuria could be explained in such cases by the existence of broncho-pneumonia, from extension of the disease, and also from high temperature.

TEMPERATURE IN DIPHTHERIA.

Dr. Ripley said that as a matter of fact it was not necessary to the production of albuminuria in these cases to have either lung complication or high temperature; that with low temperature, and with no lung trouble, casts were often found in the urine. As a rule, diphtheria was not accompanied with a high temperature; indeed, the worst cases had very often a low temperature.

Dr. Robinson said that it was very rare in his experience to see a case of diphtheria die from the disease uncomplicated with the lesion of some internal organ.

Dr. Ripley was surprised to hear such a statement, as patients were known to die of the poison within twenty-four hours after the invasion, and before there was time for any special lesion to show itself.

Dr. Robinson stated that he had made thirty very thorough post-mortem examinations during an epidemic of diphtheria, had watched the cases from the inception of the disease, and his statements were founded upon the facts which such a study demonstrated.

Dr. Lewis Smith remarked that in malignant cases during the first forty-eight hours the temperature was usually low. When such cases continued for four or five days they were attacked with nephritis.

BILIARY CALCULI WITHOUT SYMPTOMS.

Dr. Denslow presented a large number of gall-stones removed from the body of a woman who had exhibited no symptoms of their presence during lifetime.

Dr. Carpenter remarked that it was not uncommon to find gall-stones at the autopsy without a clinical history pointing to them.

Dr. Peabody alluded to the frequency with which gall-stones were found in some parts of Germany. Most of these cases presented no symptoms during lifetime.

ABSCESS OF THE LIVER—ABSENCE OF ALL HEPATIC SYMPTOMS.

Dr. Wendt presented a specimen of abscess of the liver with the following history:

The case, which had been observed at the St. Francis' Hospital, in the service of Dr. Lellman, illustrated the occurrence of purulent hepatitis without a single symptom pointing to disease of the liver. An abstract of the history was obtained from the house physician, Dr. Neumer.

G. S——, aged sixty-two years, German, married, by profession a driver, was admitted to the hospital August 30, 1880. For eight weeks previously to admission he had suffered from an intractable dysentery, and although he had been formerly a robust and powerful man, he was now emaciated and troubled with night-sweats. Upon examination, a loud, blowing murmur was found over the apex of the heart. The liver dulness was much increased, the lungs appeared normal, and the urine tests gave negative results. He complained of no pain. The enteritis was never completely controlled. He underwent an attack of peri-endocarditis, and died of pulmonary œdema on the 9th of November. The temperature had never exceeded 101° F., except during his attack of pericarditis.

On the next day an autopsy was made, and the following notes taken: Position of abdominal organs apparently normal, except that the liver extends lower down than usual. On the left side the diaphragm was at the level of the fifth intercostal space; on the right side it was pushed up to the upper border of the fourth rib.

The spleen was healthy. The left kidney was large and pale. The right kidney had a uniformly yellowish white appearance in its upper third, and the whole organ was smaller than the left.

The bladder, stomach, and small intestine seemed normal.

The *liver* was very much enlarged; there was a conspicuous bulging of the organ upward, affecting the right lobe. This was found to be the seat of a large abscess of oval shape, which left a margin of liver-substance varying in thickness from one-eighth of an inch to about one and a half inches. This abscess showed no distinct lining membrane, but there was a pretty sharp line of demarcation separating it from the surrounding hyperæmic parenchyma. The cavity of the abscess was occupied by friable masses and irregular lumps, as well as firmer bands and shreds, the whole bathed in a dirty, purulent fluid. At the most convex portion of the right lobe the diaphragm was firmly adherent, and on forcible removal the abscess was here found to have almost reached it. The pulmonary surface of the diaphragm showed a rich subpleural network of newly formed vessels just above the adherent portion. The other hepatic lobes were only moderately hyperæmic in their portal vessels.

Both *lungs* showed widespread œdema affecting all the lobes.

The *heart* was found to be moderately dilated and hypertrophied, these changes being rather more marked on the right than the left side. The aortic semilunar valves were thickened, principally at the Arantian nodules. Just above the bulbar there was a posterior dilatation, resembling incipient aneurism.

Slight atheroma was also found. One coronary artery was abnormally situated about an inch higher up than usual. Its orifice was also conspicuously enlarged, and the calibre of the whole vessel much increased. The other valves were likewise thickened, except the semilunar pulmonary valves, which were fenestrated at their free borders.

The *colon* and *rectum*, but especially the latter, showed great thickening, which involved mainly the mucous and submucous coats. The internal surface was slate-colored or black, and roughened from the presence of many superficial ulcers, with jagged edges. There were also numerous ecchymoses, and here and there diphtheritic sloughs had occurred. The mesentery and its glands were not altered.

Dr. Carpenter asked the question as to whether any pyogenic membrane existed in this case, and being answered in the negative, remarked that such a fact had an important bearing upon the statement made regarding the curability of hepatic abscess after aspiration. It was claimed by those who have aspirated the liver and evacuated pus that there was no necessity of repeating the operation, inasmuch as there was no pyogenic membrane, and that the abscess healed at once. A clinical feature in that case worthy of notice in connection with aspiration was that there were no symptoms of the presence of the abscess during life.

Dr. Delavan presented a specimen of epithelioma of the larynx, after which the Society went into Executive Session.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, Dec. 2, 1880.

Fordyce Barker, M.D., LL.D., President, in the Chair.

The Librarian reported that since the last stated meeting the library has received 78 bound and 29 unbound volumes, 185 pamphlets, and 181 medical journals. Four volumes presented by Dr. Wiener possessed special value.

THE MANAGEMENT OF ECZEMA OF THE ANUS AND GENITAL REGION

was the title of a paper read by Dr. L. Duncan Bulkley (see p. 676).

The paper being before the Academy, was discussed by Dr. Fred. R. Sturgis, who concurred with the author of the paper in the doctrines which it contained. He directed attention to a variety not mentioned, namely, that occurring in gouty subjects. He also believed that the eczema, with the thickening of the skin, were secondary to the irritation produced in trying to relieve the itching. Local remedies he regarded as purely palliative, and relied upon internal remedies, the most efficient of which were the mineral acids. He also believed that a distinction must be made with reference to the age of the disease when considering the question of local applications. In chronic cases in which the skin was thickened, but no fissures existed, he had seen excellent results follow the use of *carbolic acid and glycerine*, in the proportion of a drachm of the crystals to the ounce of glycerine, as recommended by Dr. Bronson, of the New York Dispensary. Flexible collodion had proved serviceable, and the object of its application was twofold: first, exclusion of air; and second, separation of the parts so that friction was excluded. The compressing action of the collodion was also beneficial. He agreed with the author of the paper in the statement that arsenic was inert in that class of cases.

Dr. Satterlee agreed substantially with Dr. Bulkley in his views concerning the management of the affection under consideration. The plan of treatment which he commonly adopted, however, was even simpler than that described. He thought that the combination of a saline cathartic, a saline diuretic and an alkali, simplified the treatment and also prevented the patient from taking too much medicine. With regard to local applications, he regarded the tincture of tar as the simplest and most effective—tar dissolved in methylic spirit and applied twice a day, directing that the parts be washed once a day with tar- or castile-soap and water. If the tincture of tar was too stimulating, tincture of opium might be added with benefit. The saturated solution of tar in methylic alcohol, diluted according to requirements might be used. The smarting which it produced when first applied soon passed away.

Dr. H. G. Piffard said that the internal treatment which he had found most serviceable consisted essentially in the use of oxidants, alkalies, which acted as adjuvants to the oxidants, and cholagogues. Of the oxidants, *chlorate of potassa* and *nitric acid* were those which he commonly employed; of the alkalies, the *salts of lithia*, especially the benzoate, had the preference; and of the cholagogues, the *blue flag* was his favorite, administered in doses of *ten drops* of the tincture t. i. d., which was usually progressively beneficial—immediate benefit not being produced. But the local treatment must not be neglected; and, for the purely acute eczema—occurring, perhaps, in a patient who lived somewhat sumptuously—a full dose of calomel would frequently relieve him very much, and white precipitate ointment was probably as good a local remedy as could be used. In cases of chronic eczema, the indications, besides the use of internal remedies, were first to relieve the pruritus, and second to diminish the infiltration; and as a rule, the pruritus was not relieved until the infiltration was reduced. To reduce that he knew of nothing more beneficial than *strong alkalies*, such as liquor potassa, tincture of soap, etc. For the pruritus, aconite and digitalis had been used with good results, also staphysagria and stramonium. The *caladium seguinum* in tincture he had also used sometimes with most excellent results, and again without any benefit whatever. He had seen one case of wrist-drop from the prolonged use of diachylon ointment.

In many cases fissures coexisted with the eczema, and, if they were not deep, many of them could be healed by the use of suppositories containing five to ten drops of the tincture of rhatany and one or two grains of pure plumbago.

Dr. C. Heitzman, on invitation, remarked that true science did not deal with imagination and opinions. If the question was asked, had it been proved that gout or kidney disease, etc., caused eczema, certainly the answer would be in the negative. Eighteen years of experience, mostly under the guidance of Hebra, had taught him that the disease should be regarded, primarily, as a local affection, and secondarily, as a complication of other diseases. Dr. Bulkley had mentioned defective intestinal excretion as a cause of eczema, and it was probably true that persons affected with eczema of the anus suffered from constipation; but, had we any valid reason for supposing that the peculiar quality of the fæces, or the condition of the urine, or the acridity of the bile, or the sluggishness of the portal circulation, produced the disease? Most certainly not. It should suffice to say that fissures were very commonly produced by the passage of hardened fæces, and the local irritation produced might cause eczema. The perspiration from the parts might be of such a nature as to give rise to eczema about the anus and the genitals. So far as his experience went, he must positively say that all the articles of the pharmacopœia mentioned by the author of the paper and the speakers by whom he had been preceded, were of no value whatever in the treatment of eczema. Surely the regulation of the stomach was beneficial in the treatment of skin diseases; but, was it not excellent in the treatment of any disease? Unfortunately, in very many cases it was one of the extremely difficult things to accomplish, and how often did we succeed? The same thing could be said with reference to kidney disease and other diseases upon which the local disease had been supposed to depend.

Local treatment was sufficient to cure a certain percentage of all the cases of eczema, and a certain percentage of cases would inevitably remain uncured despite any plan of treatment. If removed temporarily, the disease will return in those obstinate cases. The treatment of acute eczema should be entirely different from that adopted for the chronic form of the disease. In the acutest conditions everything that irritated, including all ointments, and also water, should be entirely avoided. The parts should be kept dry by the use of some kind of powder.

In the pustular stage of eczema ointments were indicated, and first among these was the *diachylon.* He had not seen lead-poisoning follow its use, but could understand that such a result might follow its steady use for six months.

In the squamous stage the tincture of tar was his favorite local remedy. About four or five per cent. of the patients were made worse by the use of tar, but in the ninety-five or ninety-six per cent. simple tar acted wonderfully well.

For chronic eczema the treatment must be entirely different. In such cases, with thickened skin, etc., *irritation* was indicated. Hot water, then, might be of service, carbolic acid, green soap, etc. The object was to change the chronic into an acute condition, and then cure the acute disease. In a certain number of cases that could be done, and in a certain number of cases it *could not be accomplished.*

With reference to *eczema marginatum,* a few experiments had led him to the conclusion that *sulphurous acid was not a parasiticide.*

Dr. Frank H. Hamilton regarded the chronic malady as both local and constitutional in a majority of cases. It was local in certain parts of the body, for reasons which could be readily appreciated. But it was especially obstinate in patients whose constitution had in some way been broken, and most frequently they were in an anæmic condition. His memory, during the discussion, had been burdened with panaceas, and he had been led to the conclusion that something was lacking in the mode of bringing the subject before each other. We should have some broader principles than could be deduced from the mere relation of personal experience. It was evident that the majority of remedies recommended for chronic eczema were stimulating, and that unless they did produce irritation they were useless. Dr. Hamilton referred to one case in which the eczema was aggravated by the use of tobacco, thus showing a possible neurotic element in certain cases.

Dr. Sturgis entered his protest against the doctrine that eczema was a purely local affection. He believed, despite the fact that it might not be scientific, that in very many of the cases the eruption was the localized manifestation of a constitutional affection, and that, although local remedies were undoubtedly serviceable, internal medication was necessary to effect a permanent cure.

Dr. Piffard believed that if physicians were obliged to depend upon facts alone, they would have but little upon which to depend. Something must be done in accordance with inference. Constitutional conditions preceded and coexisted with the development of eczema, and when those conditions were removed, or even relieved, in many cases the skin disease disappeared. It was a legitimate inference, therefore, that the eczema was only a local manifestation of a constitutional condition, even if it was not proved positively that the one caused the other.

Dr. Sherwell, of Brooklyn (on invitation), had studied with Hebra, and had great respect for his teacher, but, at the same time, believed that he was mistaken concerning the purely local origin of all skin diseases. Dr. Sherwell believed that eczema was caused by diathetic conditions. It was natural that all should seek to cure eczema with local remedies, and there was a certain plan of local treatment by which a large number of cases could be cured. He believed in the depurative action of many remedies, especially of calomel, and knew that it was beneficial in many cases of this affection. He thought it unwise to adopt exclusively the views of any single school of observers.

Dr. Bulkley remarked that cases of eczema had been treated year after year with local remedies without benefit, and then cured by the simple addition of constitutional measures, hygienic, etc.; thus proving that the disease had had other than a local origin.

The resignation of Dr. E. R. Squibb as a resident fellow was accepted, after which the Academy adjourned.

Correspondence.

SUBCUTANEOUS EMPHYSEMA DURING LABOR.

To the Editor of The Medical Record.

Sir—In the Medical Record, No. 526, page 629, I find that subcutaneous emphysema is reported as being of somewhat unusual occurrence, and concluded, with your permission, to place another case on record. It is as follows:

Rosa P——, aged nineteen years, primipara. Was called to see her April 13, 1880. She was a healthy, vigorous person, slightly below medium size. A midwife who had been in attendance, when she found the breech presenting, gave up the case and said a physician must be called. She had been in labor several hours; the uterine contractions were not very strong; considerable time elapsed before the body of the child was delivered; in order to expel the head she made several very powerful efforts at bearing down. Immediately after the child was born she complained of pain in her throat, her neck was swollen, and slight crepitation could be felt. The swelling increased rapidly; her face became cyanotic; she complained of an uncomfortable sensation about her neck and chest; swallowing caused a pain as if a pin were sticking in her throat.

I ordered cold applications to her neck, told her not to be alarmed, and that she would be better in the morning. When I again saw her the next morning her face was disfigured by the swelling, her neck was puffed out even with her cheeks, crepitations could be felt all over the temporal and occipital bones, and downward the emphysema extended as far as the lower edge of the mammæ and ensiform cartilage of the sternum, and both arms almost to the elbow-joints.

I was very much alarmed when I saw her in this condition, but, ascertaining that there was no dyspnœa and that she could swallow fluids readily, besides not knowing what to do to prevent any further swelling, I concluded to let her alone and await further developments.

The emphysema did not extend any farther, and, after remaining in this condition about two days longer, it began to subside. Ten days after her confinement no crepitations could be felt anywhere.

Yours, respectfully,
L. Haupt, M.D.

63 Rivington Street, N. Y.

AN UNUSUAL CASE OF INTUSSUSCEPTION.

To the Editor of The Medical Record.

Sir:—The following case, which has been recently the subject of remark in the Record, presents some points of unusual interest and importance in the diagnosis of intestinal intussusception:

F. A. F——, colored, aged six months, was brought to my office August 3, 1880. His mother, an intelligent mulatto, offered the following history: The infant, who had been quite healthy from his birth, except that, as the mother expressed it, "he always was a very colicky baby," awoke about 5 A.M. on the preceding day, crying out in an apparent attack of ordinary colic. This attack soon passed by, and the infant continued, to all appearances, as well as usual during the remainder of the day, though his bowels moved three times. He slept well during the early portion of the succeeding night, but awoke again early on the morning of the 3d, and renewed his screams of pain. Ordinary domestic remedies failing to procure relief, he was brought to my office about 10 A.M. The mother reported that he had been vomiting frequently during the morning, but that he had no diarrhœa, and his bowels had been moved by an enema. At this time the infant was sleeping in his mother's arms, but occasionally moved uneasily with a half-suppressed cry. His skin was cool, bowels soft and free from tenderness, and the vomiting had ceased for an hour or two. Supposing the case to be one of ordinary indigestion, castor-oil was prescribed to move the bowels, and an opiate mixture for subsequent administration.

About two o'clock of the succeeding night (4th) I was called to see the child, and informed that the castor-oil and several doses of the mixture had been taken, but that no movement of the bowels had ensued until about half-past one, A.M., when a bloody stool had been passed. The napkin was shown to me, and apparently contained about one and a half to two fluid ounces of bloody serum, with little or no fecal matter. No vomiting had occurred, although the infant had nursed several times, but attacks of colicky pain and straining had been frequent and severe. Temperature in rectum, 101° F. bowels soft and free from tenderness. Suspecting a possible intussusception, the rectum and abdomen were carefully examined, but no tumor was detected I ordered a flax-seed poultice to the abdomen and liq morphine sulph. (U. S.), gtt. v. every one to two hours until pain and straining were relieved.

11.30 A.M.—Infant fully under the influence of morphine; no vomiting, no movement of bowels, which continue soft and free from apparent tenderness. An effort was made to inflate the bowels through a catheter in the rectum, but proved ineffectual, as the air escaped per anum in spite of compression. Morphine continued p. r. n., and poultice to the abdomen.

8 P.M.—Infant has manifested very little pain, though no morphine has been given since my previous visit. No vomiting or movement of the bowels. Suspicion of a tumor in left iliac fossa, where some tenderness, resistance to deep pressure, and slightly impaired resonance are manifested. No tumor in rectum. Child inverted upon arm of a lounge and about three-fourths pint of warm salt water slowly injected until returned by anus. Bowels gently kneaded, and child kept inverted for half an hour.

Third day, 9 A.M.—Child passed a very restless night, crying out frequently with pain. Injection of last night came away, but no feces. Infant quiet under morphine at present. No vomiting has occurred, but he refuses to nurse. Injection of salt water repeated, and apparently passed some distance into the descending colon, producing dulness nearly up to the ribs on the left side. Consultation proposed looking to operative interference.

4 P.M.—No marked change. Injection came away without fecal matter. As a last resort, the infant was inverted, and two ounces (by weight) of metallic mercury injected through an elastic catheter as high as possible into the rectum. The inverted position was then maintained for a full hour without apparent suffering.

8.30 P.M.—Requested my friend, Dr. S. Whitall, to see the case with me, prepared to operate should such a course seem justifiable. A portion of the mercurial injection had escaped on the restoration of the infant to the erect position; the remainder came away during Dr. Whitall's examination. Pulse, 160; temperature (rectal), 102⅗° F. Considerable tympanitis; no tumor discoverable either in rectum or abdomen; no vomiting, no movement of bowels, very little apparent pain or straining. After a prolonged and careful examination, Dr. Whitall declined a positive opinion, considering a differential diagnosis between intestinal obstruction and peritonitis uncertain for the following reasons: 1st, the entire absence of vomiting since the first day; 2d, the absence of bloody stools since the same day; 3d, the slightly marked character of the pain and straining; 4th, the absence of any apparent tumor; 5th, the elevated temperature. While strongly inclined to consider the case one of intussusception, I could not fail to recognize the justice and importance of Dr. Whitall's objections, and after some discussion we both concluded that, as considerable doubt remained regarding the diagnosis, so severe an operation as abdominal section would be unjustifiable. We therefore decided to adminster calomel, gr. vi., with morphine p. r. n., and to apply turpentine stupes to the abdomen.

Fourth day, 9 A.M.—Pulse, 160; temperature, 103⅗° F. No movement of bowels; tympanitis much increased; turpentine enemas administered ineffectually. Ordered brandy, gtt. x. every hour, with morphine for pain.

3 P.M.—No change. Abdomen punctured in two points with hypodermic needle. Gases escape with distinct whistling sound and fecal odor. Tension of abdomen distinctly diminished.

8 P.M.—Pulse, 180; temperature, 105½° F. Abdomen greatly distended, punctured again but without apparent effect. Infant takes milk freely, and has vomited once during the day.

Fifth day.—Infant died at 7 A.M.

Post-mortem (3 P.M.).—Present: Drs. Whitall, Hawes, and Handerson. Abdomen alone opened. No evidences of peritonitis. Small intestines greatly distended. A portion of the ileum and the caput coli invaginated within the ascending colon for about three inches. The invaginated intestine, though much congested, was withdrawn without great difficulty, and no adhesions were discovered. Mesenteric and solitary glands enlarged. The tumor formed by the intussusception was found in the epigastric region, totally covered and concealed by the distended small intestines. Its position was due to a displacement of the ascending colon, and not to an invagination of the bowel as far as this point.

It may not be superfluous to summarize the foregoing history as follows: A case of intussusception proceeds to a fatal issue on the fifth day, having manifested as symptoms: 1, one single bloody stool, occurring within the first twenty-four hours; 2, no vomiting of importance after the first six hours; 3, no very intense pain nor straining; 4, no discoverable tumor; 5, a considerable elevation of temperature; 6, obstinate constipation.

H. E. Handerson, M.D.

784 Lexington Avenue, Nov. 29, 1880.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from December 5, 1880, *to December* 11, 1880.

Brown, J. M., Capt. and Asst. Surgeon. Granted leave of absence for one month, with permission to apply for three months' extension. S. O. 264, Department of the Missouri, December 2, 1880.

O'Reilly, R. M., Capt. and Asst. Surgeon. The extension of his leave of absence on account of sickness granted him August 16, 1880, still further extended six months, on surgeon's certificate of disability. S. O. 259, A. G. O., December 7, 1880.

De Loffoe, A. A., Capt. and Asst. Surgeon. Relieved from duty at camp on White River, Col., and assigned to duty at Fort Wallace, Kan. S. O. 269, Department of the Missouri, December 8, 1880.

Hall, Wm. R., Capt. and Asst. Surgeon. Assigned to duty at camp on White River, Col. S. O. 269, C. S., Department of the Missouri.

The State Charities Aid Association held a two days' conference in this city last week. Various papers upon the subject of how to take care of the indigent, the paupers, and the insane, were read. All these papers and the discussions that followed were adverse in spirit to the practice of *indiscriminate giving.* Nothing was said, however, about one of its worst forms of charity, that of indiscriminate medical relief.

Medical Items and News.

Contagious Diseases — Weekly Statement. — Comparative statement of cases of contagious diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending December 11, 1880.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro spinal Meningitis.	Measles.	Diphtheria.	Small-pox.	Yellow Fever.

Dec. 11, 1880.	0	18	180	2	28	166	5	0

Annual Meeting of the American Public Health Association.—The annual meeting of this Association took place at New Orleans, December 7th, 8th, 9th, and 10th, about one hundred members being present. The President, Dr. John S. Billings, was in the chair. Several new members were elected at the first day's session. The first papers were by Dr. Gustavus Devron and Dr. B. W. James, on "Abattoirs." Dr. Joseph R. Smith, U.S.A., read a paper on "Texas Cattle Fevers," in which he contended that no epidemic disease prevailed among native Texas cattle, but that a great number of imported cattle suffered from acclimating fever. The paper of Dr. Smith gave rise to some interesting discussion.

A report of the committee on a plan to prevent the spread of contagious diseases was read by A. G. Gibson, U.S.A. The report concluded with a resolution recommending legislation making it a criminal offence knowingly to communicate contagious disease, and providing for gratuitous treatment. After some discussion the resolution was adopted.

On the second day twelve papers were read by different members, more or less discussion following them. Among these were papers by Dr. G. B. Thornton, of Memphis, on the sanitation of that city, which had been in a bad sanitary condition, but was now reclaimed; a paper by Prof. Gamgee, of Washington, setting forth the sanitary value of a Florida ship canal, and the commercial advantages of such a canal. It was urged that ships could avoid the hot pestilential regions of the Caribbean Sea, and undergo quarantine inspection in the canal. A paper was read by Dr. D. C. Haliday, of New Orleans, on "Dengue Fever," describing its characteristics and the diagnosis between this disease and yellow fever. Papers on the same subject were read by Dr. J. G. Thomas, of Savannah, and Drs. Peyre Porcher and Horlbeck, of Charleston.

At the evening session Dr. E. M. Hunt, of Metuchin, N. J., read a paper on "The Present and Needed Knowledge of Epidemics," in which he discussed the germ theory of disease in its various bearings. The Hon. John Eaton, of Washington, Commissioner of Education, read a paper on "Sanitation and Education." The object of the paper was to show how increase of knowledge fostered the development and dissemination of sanitary truths. Illustrations were drawn from the history and progress of modern times to demonstrate the value of sanitation. Special attention was given to the subject of sanitation in the training of teachers and pupils in the schools. The paper was long and exhaustive.

On the third day a large number of papers were read, including one by Dr. A. N. Bell, of New York, on the "Relations of Certain Filth Diseases to Cold Weather." A general discussion of all the papers on communicable diseases ensued. Secretary Janes read a paper of Mr. James Gallatin, President of the Sanitary Reform Society of New York, on tenement-house reform in that city. Prof. T. E. Chaille, M.D., of New Orleans, followed with a paper on "The Control of Contagious Diseases in Relation to the Doctrine of Evolution." The Hon. Erastus Brooks, of New York, read a paper on "The Duty of the State to the People." The proposition demonstrated was that the public health was public wealth, and that the science of health was highest in political economy.

On the last day, in addition to the discussion of reports, resolutions, etc., Prof. R. E. Chaille, of New Orleans, read a paper giving a summary of the conclusions of the Havana Yellow Fever Commission, of which he was President. Dr. J. D. Bruns, of New Orleans, read a paper on "Fevers of the Lower Coasts."

There were nearly thirty papers read in all.

Among the resolutions offered was one by Dr. McCormick, of Kentucky, appointing a committee to consider the advisability of establishing a National Museum of Hygiene.

Dr. Chancellor, of Maryland, offered a resolution advising legislation for the better protection of the public health, and imposing a severe penalty against any person wilfully spreading any dangerous, contagious, or infectious disease. Mayor Waltham, of Mobile, introduced a resolution appointing a committee to prepare and recommend a measure for the more efficient management and control of future epidemics, and for the training of nurses. The Advisory Committee submitted a report treating of the sanitary bills before Congress, especially the bills relative to the international conference on quarantine, and for increasing the efficiency of the National Board of Health. It does not recommend any change in existing legislation, but urges that Congress make suitable appropriations for the work of the National Board, and authorize the prompt publication of reports.

The Committee, with Dr. Elisha Harris, of New York, Chairman, appointed to consider certain portions of the President's address, reported resolutions commending the efforts of the National Board of Health to secure uniformity in the notation and nomenclature of diseases and causes of mortality, and requesting medical and health authorities to do what they can to promote this uniformity. A committee was appointed to draw up a project for State Boards of Health of a law to prevent venereal diseases. Resolutions were adopted requesting the passage of a law to prevent the spreading of infectious and contagious diseases.

The following officers of the Health Association for the ensuing year were elected: President, Dr. Charles B. White, of New Orleans; First Vice-President, Dr. R. C. Kedzie, of Lansing, Mich.; Second Vice-President, Dr. Henry F. Campbell, of Augusta, Ga.; Secretary, Dr. Azel Ames, of Boston; Treasurer, Dr. J. Berrien Lindsay, of Nashville; Executive Committee, Drs. D. C. Halliday, of New Orleans, E. M. Hunt, of New Jersey, George M. Steinberg, U.S.A.; E. S. Griffin, Wisconsin; J. G. Thomas, Savannah; Thomas F. Wood, North Carolina.

The Association adjourned, to meet next year at Savannah, Ga.

At the same time with the American Public Health Association meeting, the Sanitary Council of the Mississippi Valley and the Quarantine Convention held their annual sessions.

The Muhlenberg Hospital is the name of a new institution, nearly completed, in Plainfield, N. J. The board of managers have completed the organization of the medical board as follows:

Medical Board.—Dr. H. D. Burlingham, Physician-in-Chief; Dr. Chas. A. Hart, Surgeon-in-Chief; Dr C. H. Stillman, Consulting Physician; Dr. J. E. Janvrin (New York), Consulting Surgeon; Dr. C. M. Field (Bound Brook), Consulting Surgeon. *Medical Service.*—Dr. J. B. Probasco, Dr. T. H. Tomlinson, Dr. W. C. Boone. *Surgical Service.*—Dr. M. B. Long, Dr. G. W. Endicott.

The building will accommodate twenty patients.

The Miracle-Cures at Lourdes and Knock.—Something of a sensation has of late been aroused regarding the subject of the reputed miraculous cures at Lourdes, in France, and at Knock, in Ireland. Some remarkable cases have been reported in the daily papers. An eminent Episcopalian divine, Dr. Stephen Tyng, Jr., has announced from his pulpit that he has visited both places, has examined into the occurrences, and believes in their supernatural character. The *New York Times*, in an editorial comment, gives what is apparently meant as an endorsement of Dr. Tyng's belief. Of course, the religious weeklies have taken their share in the discussion, generally repudiating the phenomena altogether.

The two localities in question have obtained a remarkable reputation, and there is the profoundest confidence in their virtues among faithful Catholics, as well as many others.

The question of whether or not miracles do occur there is not worth discussing. The matter is a very interesting one in its psychological aspects, however, and undoubtedly would well repay any careful and scientific study that might be put upon it. Unless the numerous instances of relief obtained are entirely fictitious, which is highly improbable, the influence of the mind upon the body and the power of "expectant attention" are vividly illustrated in some of these "miraculous" cures.

State Emigrant Lunatic Asylum.—Dr. Louis L. Seaman was appointed Superintendent of the State Emigrant Lunatic Asylum on Ward's Island, in place of Dr. S. Feinberg, resigned.

A Prince Earning his Living as a Physician.—It is stated that Charles Theodor, Duke of Bavaria, who recently received a medical degree, has successfully performed his second operation for cataract. A correspondent of the London *Telegraph* writes concerning him:

"The prince is a regular attendant at Prof. Arlt's lectures on diseases of the eye, and has in no respect relaxed the arduousness of his studies since he has become a regularly licensed member of the Faculty. Indeed, if reports speak truly, his Royal Highness, Dr. Charles Theodor von Wittelsbach, is fairly on the way to attain high rank among the more eminent practical oculists of Southern Germany. In choosing so noble a profession, not as a mere pastime, but with the high resolve of alleviating human suffering, this illustrious gentleman has set a splendid example to his fellow-princes, the majority of whom, unfortunately, have hitherto displayed a greater predilection for the study of science aiming at the destruction rather than at the saving of life."

Original Lectures.

ON THE VALUE OF

PARTIAL INTOXICATION IN THE PREVENTION OF SHOCK DURING OPERATIONS.

A Clinical Lecture.

By STEPHEN SMITH, A.M., M.D.,

SURGEON TO BELLEVUE AND ST. VINCENT'S HOSPITALS, NEW YORK

Gentlemen—This young lady is about to submit to an operation for the removal of dead bone from the region of the hip-joint, the result of long-continued disease at that articulation. I shall reserve to another occasion the discussion of some interesting questions bearing on the management of this and similar cases, and occupy the few moments allowed me in explaining what is to you the most prominent feature of her case, viz., unusual good humor and vivacity, as compared with young women brought into this room for serious operations.

As you notice, she is in an extremely happy frame of mind for one evidently so sensitive and excitable. Her face is flushed, her eyes suffused, her skin warm and natural, her pulse full and slow, her breathing quiet and undisturbed. Although she has been in great dread of being brought into your presence, and of undergoing an operation, yet she talks and laughs like one whose nervous system was simply exhilarated by the society of friends or the stimulus of an exciting but agreeable scene.

The explanation of her condition is this: she is partially intoxicated, or "half seas over," using a common but expressive phrase. We have purposely brought her into this state in order to prepare her for the operation. During the last five hours she has been supplied with whiskey at regular intervals, until she has taken six ounces, when the desired effect was secured, viz., partial intoxication. She is perfectly rational when you talk with her, and knows her condition, but is disposed to regard everything you may say as ludicrous—that is, she is insensible to danger, and in the most hopeful state of mind and body, in good condition for the operation.

My justification for this treatment is based on no inconsiderable experience. It happens, not very unfrequently, as some of you have witnessed, that operations are interrupted by the sudden and unexpected collapse of the patient. The surgeon may have reached a point, perhaps, at which there is a slight hemorrhage, when the patient quickly passes from a state of proper narcosis to that of profound prostration. The face assumes a deathly pallor, large drops of sweat start from the forehead, the skin becomes cold and clammy with perspiration, the breathing is irregular and scarcely perceptible, the pulse is feeble, rapid, and irregular, and every sign and symptom indicate immediate dissolution. The operator and attendants are alarmed, the operation is abandoned, and all hands and heads are turned to avert impending death. In the belief that too much ether has been given the anæsthetic is withdrawn, the chest is violently compressed under the pretence of causing artificial respiration, brandy or ammonia is injected under the skin, and at length the patient usually recovers sufficiently to allow of the rapid completion of the operation. But occasionally death supervenes despite the most persistent efforts to prevent it. If the patient recover from the depression, convalescence is slow and tedious, and the operation wound heals tardily and with an unusual tendency to suppuration.

An attack of this kind is not narcosis from anæsthesia, but shock, and generally in its most aggravated form. It occurs especially in those of great nervous susceptibility, or who have already suffered severely from the shock of injury, or who are prostrated by the exhaustion consequent upon long-continued illness, suppuration, or other cause.

As a preventive measure against shock in these cases, during an operation, partial intoxication of the patient with whiskey, brandy, or rum, will be found safe and reliable, and far preferable to quinine, opium, etc. The patient who has been laboring under great excitement in anticipation of the operation gradually becomes quite indifferent, or even bold and daring; the pulse is full and slow; the respiration undisturbed; the ether is quietly inhaled; but little, comparatively, is required; the stage of excitement is brief, or is passed without a struggle. During the operation, however prolonged, the pulse varies but slightly, unless there is a considerable loss of blood, and even in that case it maintains sufficient force to allow the operation to proceed to its completion. After the operation the pulse maintains its vigor, there is slight if any reaction, and the temperature remains nearly normal for the first twenty-four hours.

This practice is based upon the experience of surgeons anterior to the period of the use of anæsthetics. With them it was a well recognized fact that persons partially intoxicated at the time of the accident which necessitated the amputation, not only bore the operation with slight evidence of pain or shock, but made the best recovery. In a case of this kind I was impressed with the behavior of the patient. A man partially intoxicated entered the hospital with a crushed foot, which necessitated the amputation of the leg. He was talkative and quite indifferent both to the accident and to the proposed operation. Though the injury had occurred two hours before admission, there were but slight evidences of shock. His pulse was full and little excited, the skin was warm, the respiration undisturbed. I took advantage of his condition to amputate immediately. It was noticeable that he required but very little ether, that his pulse and respiration did not vary; in a word, that there were no evidences of shock. For twenty-four hours after the operation his pulse remained undisturbed, his skin warm and natural. He recovered within a period less than that usually occupied by similar operations.

The first case in which I purposely induced partial intoxication to prevent shock occurred many years ago. The patient was a young woman of naturally great nervous susceptibility, who was reduced to a very feeble condition by long-continued suppuration from caries of the tarsus. Amputation was advised, and although she was extremely anxious to have the operation performed, yet when the effort was made her excitement was so great that it was deemed dangerous to proceed. Twice she was placed upon the table, and the anæsthetic, at one time chloroform and ether at the other, was administered; but her pulse became so rapid and feeble, her respiration so embarrassed, her lips becoming purple, that the operation was abandoned. Finally, as a last resort, it was determined to give stimulants several hours before the operation, and until she was decidedly intoxicated. The result was most happy.

When she had taken eight ounces she was in the condition of this patient, quite indifferent to the operation, her pulse was full (at 96), and her respiration tranquil. But a very small amount of ether was required, the amputation was performed, the limb was dressed, and she was placed in bed. There was no variation in the pulse or breathing during the operation, nor for twenty-four hours after. She did not discover that the amputation had been performed for sixteen hours, and, on learning the fact, was overjoyed. She made a rapid recovery.

There is another class of cases that is very favorably affected by stimulants taken during several hours preceding an operation, to the extent of partial intoxication. They are persons suffering from an enfeebled condition of the heart, and are noticeably overloaded with fat. They are very liable to succumb to even a very slight shock of the operation, when combined with the effects of the anæsthetics. The face rapidly becomes dusky, the lips purple, the respiration embarrassed, and the pulse feeble and irregular. Efforts at resuscitation sometimes prove unavailing, and the patient dies upon the table. As a preventive measure we usually give an ounce or two of whiskey just preceding the operation, and doubtless it often does prevent disaster, by arousing the heart and invigorating the circulatory organs. But such results are far more likely to be obtained if the stimulus is steadily given, in quantities suited to the condition and habits of the patient, for several hours preceding the operation. Reverting again to our patient, I must state that she is eminently a proper subject for this preparatory treatment. She entered the hospital a fortnight since, suffering from suppuration throughout the thigh, due to extensive and long-existing caries at the hip-joint. She was cadaverous in appearance, had irregular chills followed by profuse perspiration, a rapid, feeble pulse, and no appetite. Under an active tonic treatment her general condition has improved, but she is not in a state to bear safely the slightest depression from shock. The effect of the stimulant has been to give more strength and steadiness to her pulse, a warmer skin, and more cheerfulness than at any time since her admission. I do not doubt that she will bear the operation well, and that there will be no shock, unless there should be a sudden loss of a very large amount of blood. The plan which I pursue is to commence the intoxicant five or six hours before the operation, and give one, two, or three ounces every hour, according to the habits and condition of the patient. This patient required six ounces of whiskey to bring her into her present state, the first ounce having been taken six hours ago. A few days since, an old drinker required sixteen ounces to induce the condition of this young woman. I have always used whiskey, and have occasionally given it in the form of milk-punch.

[It should be stated that during the operation the patient required but little ether; the pulse continued at 96, full and soft; the respiration was undisturbed. After the operation the pulse and respiration continued unaffected; there were no evidences of shock; no fever supervened; suppuration rapidly subsided; her general condition improved surprisingly, and in two weeks she resumed her hip-splint.]

CHLORAL HYDRATE.

By H. H. KANE, M.D.,

NEW YORK.

DEATHS FROM CHLORAL.

To one unacquainted with the literature of the subject the number of recorded deaths from chloral hydrate is astounding and greatly to be deplored, as in the majority of instances they have been due to ignorance or carelessness on the part of physician or druggist.

It has been asserted by some that susceptibility to the poisonous effects of chloral is in direct ratio to the cerebral development of the animal or man. This is, at best, a supposition, and is in great need of positive facts to support it.

The following are the most important cases of death of which I have been able to obtain any reliable information, and they supplement, very aptly, what has been said regarding poisoning by chloral hydrate.

Dr. Chas. A. Hart[*] gave twenty grains to a patient suffering from neuralgia. Death followed in thirty minutes, probably from failure of the heart.

G——[†] gives the case of a man aged forty-nine years, with ulceration of the mucous membrane of the bladder, and bronchial trouble, where fifteen grains of chloral hydrate seemed to cause death. He had a horror of chloroform, and in fact, of all narcotics, believing that he was nearly killed once by chloroform. He died suddenly while at stool, fourteen hours after having taken the dose. There was no autopsy, and the facts do not warrant us in saying that death was due to the small dose of chloral.

Dr. H. W. Fuller[‡] reports the case of a young lady in excellent health, who, for sleeplessness, was given thirty grains of chloral. It at first produced pain and burning in chest and considerable excitement. This passed off and she fell asleep. Became pulseless, with cold extremities. Responded somewhat to stimulants and warmth, but never regained consciousness. Dose given 10 P.M. of the 31st of December. Died January 2d, about 9 A.M.

Mr. Tuke informed the author of the case of an intemperate man who nearly died from the same dose. A similar case, in an old man, was related to him by Mr. Fred. Webb.

In the last *American Practitioner* is recorded an instance of remarkable and fatal susceptibility to chloral. A physician of Louisville was called to a healthy-looking woman threatened with premature labor, and gave her fifteen grains of chloral every fifteen minutes. Four doses were taken, the last being increased to twenty grains, making sixty-five grains in all. Soon after she sank into a profound stupor with slow and stertorous breathing, scarce perceptible pulse and cyanosed skin. Atropia, strychnine, whiskey, strong coffee, carbonate of ammonia, electricity, etc., were used, but without benefit; she died next day. Premature delivery occurred some hours before death; the child was still-born.[§]

Ingalls[‖] reports the case of a perfectly healthy

[‖] Chicago Medical Examiner.

German woman who was given ten grains of chloral to dull the pain of having a tooth drawn. In an hour's time she was given ten grains more, twenty in all, and she soon fell into a state of coma and died despite every effort to save her.

Dr. Samuel T. Hubbard * reported to the New York Academy of Medicine the case of a lady who had an old prescription for chloral hydrate renewed, took ninety grains and died. No autopsy.

Dr. A. R. Kilpatrick of Navasota, Texas, writes: "A druggist who had suffered long with fistula was unwilling to submit to an operation without an anæsthetic. The physician who was to perform the operation was an enthusiastic advocate for chloral, in all cases preferring it to chloroform. The patient was in favor of chloroform, but the doctor induced him to substitute chloral. Everything was made ready and the chloral was administered in unknown quantities, as he, the doctor, poured out the salt in his hand and poured it in a goblet, made the solution and gave two or more doses. (?) As the patient became insensible, a thorough examination of the fistula was made, which he never would submit to before, and it was found there was either tubercular or cancerous complication. At this stage of the proceedings the patient became blanched and cyanosed, the respiration was impeded, and other marks of dissolution were present. All efforts at restoration failed, and the patient died. It was known that one or both lungs were tuberculous. This was in 1871. There was no autopsy. It was believed, and so stated by some of the physicians present, that the patient probably took over two hundred grains, or perhaps more, of the hydrate of chloral, in a space of time not over two hours."

Another case of death from an overdose of chloral hydrate may be found in the London *Lancet*, February 27, 1875, also in the *Medical Press and Circular*, November 12, 1879, the victim being a physician, a Dr. Wm. Hay, a well-known practitioner at Carlisle.

Dr. J. W. F. Webb, of Liberty, Miss., writes me of two deaths from chloral hydrate occurring near that place. One was that of a physician who believed that chloral was harmless in any dose, took 480 grains, and paid the penalty of his ignorance with his life.

F. Jolly † (*Bayer. aerztl. Intell.-Blatt*) states that, in the course of two years, during which he has employed the hydrate of chloral in the treatment of the insane, he had met with two cases of sudden death following its use. The dose was in each case below the average, and the drug was chemically pure. The patients during life presented no contra-indications to the use of the remedy. One had taken chloral at night for four evenings in succession. On the fifth evening after taking it the respiration and circulation at once ceased. The necropsy showed anæmia of the brain, acute œdema of the lungs, hyperæmia of the abdominal organs, a perfectly healthy heart and vessels, and dark fluid blood.

In the other case chloral had been given twelve days in succession, with the effect of producing sleep, after a short stage of excitement. On the thirteenth day the patient died, after some stertorous breathing, a quarter of an hour after the dose. There was found moderate œdema of the lungs; blood was fluid, and normally distributed; the heart was large and flabby, and its muscular structure was pale but not friable.

Prof. Nathan R. Smith reports * a case of death from 180 grains of chloral in divided doses. The same gentleman reports another case where death was caused by chloral after a subcutaneous injection of morphia.

Wm. Bragg, of Brooklyn, aged twenty-seven years, worn out with watching a sick father, saw a bottle labelled "Hydrate of Chloral;" sent to the drug store and had it filled, took ninety grains, and died. Coroner's jury censured druggist.†

Dr. T. C. Finnell ‡ reports the case of a ballet girl, aged twenty-three years, who aborted at six months. Little hemorrhage, and patient seemed doing well. Somewhat restless. Attending physician, to procure sleep, gave about ℥ ss. chloral at 10 A.M. Slept well. Dose repeated by husband, according to the doctor's orders, at 8 P.M. Half an hour later the woman died. The friends noticed that after the first dose she became cold, and that after the second the coldness suddenly became alarming, when she died.

At the autopsy, fourteen hours after death, the weather being intensely cold, and the body being kept in a cold room, Dr. Finnell was surprised to find marked evidences of decomposition—even more than that found in bodies of persons dying of sunstroke in hot weather. Only the abdominal and pelvic cavities could be examined, owing to interference of friends. Everything was found perfectly healthy.

Members of the Pathological Society, before whom the history of the case was read, were of the opinion that no conclusions could be drawn from it, owing to the imperfection of the autopsy and the fact that no inquiry had been made as to the purity of the drug.

Dr. Edward Bradley, of this city, writes me of a case where 240 grains were taken for suicidal purposes with success.

Death from 480 grains in an hour's time is reported in the *Pharmaceutical Journal*, July 2, 1870.

Dr. G. G. Davis, Frewsburg, N. Y., writes, but can give no particulars, of a case where fifteen grains proved fatal. It was given to quiet sleeplessness of consumption. The coroner's jury decided that death was due to the chloral. It occurred near Pittsburg, Penn.

In the *Journal of Psychological Medicine*, for 1871, Dr. Geo. C. Needham reports a case of death from chloral. The lady, a very nervous and excitable woman, was seen by Dr. Needham, who called Dr. Wm. A. Hammond in consultation in November. He found the retinal vessels, especially the veins, enlarged, tortuous, and increased in number, and was of the opinion that there was a condition of passive cerebral congestion present, and that there was a strong hysterical diathesis existing in the patient. He recommended chloral hydrate for this condition. This drug, with potass. bromid. and zinc. oxid., was used with apparent benefit. A seton was also put in the nape of the neck. This in February.

In October she became again worse, being extremely violent, due to the circumstances attending the death of a relative. Her condition being apparently the same as in the preceding fall he ordered chloral. On the day before taking chloral she had had 115 grains potass. bromid., and was strongly under its influence. The chloral was put up by a reliable druggist in the doctor's presence. He gave in all six doses, a part of each dose being spilled in giving. On the 21st October she had two doses, thirty grains each; on the 22d the same; on the 23d three doses, same; in all, 210 grains.

* N. Y. Medical Record, 1871, p. 379.
† Ibid., 1872, p. 324.

* Boston Medical and Surgical Journal, 1871.
† N. Y. Medical Record, 1871, p. 134.
‡ Ibid., p. 91.

She was found sleeping on the 22d, also at two visits on the 23d. On the 24th he became alarmed at her prolonged sleep, and endeavored to awaken her. In this he was only partially successful. Pulse, 108; respiration, 27. Pupils moderately contracted. Did not respond to calling or any irritation. Three subcutaneous injections of strychnia (one-thirtieth grain each) were given during night of 24th. Breathing 28–30, somewhat stertorous; catarrhal accumulations in fauces. Pulse, 108–110, strong but not full. Pupils contracted. Some voluntary motion of limbs slight during day; more pronounced during night. At 4 A.M., 25th, time of last injection of strychnia, she grew worse. Pulse, 120. Temperature of head slightly diminished. Died at 3.55 P.M., comatose.

Autopsy, six hours after death. Head alone examined. Made by Dr. T. M. B. Cross, Resident Physician New York State Hospital for Diseases of the Nervous System. No traces whatever of previous inflammation.

"The vessels of the pia mater were enormously enlarged and gorged with blood, and there were very many more of them visible than are seen in a normal brain. In the meshes of this vascular membrane there was infiltrated a sero-gelatinous exudation, more marked along the course of the arteries and veins than elsewhere, and which appeared to be in the arachnoid, but this was not the case." Cerebrum normal, save for excess of blood. No fluid in ventricles. Blood present in very marked excess.

"The pons varolii was surrounded by such a plexus of capillaries that its tissue proper could hardly be distinguished. All the sinuses of the brain were, like the longitudinal, completely filled with blood." The ganglia, crura, choroid plexuses, nerves, and all other parts abnormally vascular, otherwise normal. Blood in vessels more or less coagulated, but no rupture and no extravasation found.

There had been suspicion of heart disease by a physician who had previously attended her, but Dr. Needham had examined the chest several times, and could find nothing.

If it was not for the theory that chloral acts by transformation into chloroform, Dr. N. would believe that the lady was killed by the cumulative action of the drug.

He says, also: "It seems to me not unlikely that it will be found dangerous to administer the full dose of chloral immediately after the suspension of a long course of bromide of potassium, since the power of the latter to contract the cerebral vessels must tend to diminish their natural contractility, and the reaction therefrom may allow of so great an increase of the normal primary effect of the chloral as to produce fatal congestion."

This is negatived by the case of an epileptic boy (Hammond), who took 75 grs. chloral, with benefit, daily, for fifteen days. He had previously been upon the bromides.

Dr. Schlangenhausen, First Asst. Phys. to the Lunatic Asylum, Hall, Tyrol, reports* two cases of death, possibly from chloral hydrate. In one, a hard drinker, death followed two doses (60 and 30 gr.) in an hour's time. The drug was given to quiet very severe delirium. The autopsy showed acute œdema of the brain.

In the other case, that of an insane lady, aged forty-five years, who had been using chloral for some months in daily doses of 2 grammes, death took place four hours after a dose of 60 grains. Autopsy showed chronic hydrocephalus, with hypertrophy of the heart and mitral insufficiency.

Dr. Willis P. King, of Sedalia, Mo., writes me of a woman who was given 40 grains to produce anæsthesia sufficient to permit the extraction of a tooth. She was twenty-eight years old, and healthy. The dose was repeated in twenty minutes (80 grs. in all). She passed rapidly into profound coma, with rapid pulse, cold extremities, clammy perspiration, etc., and died within an hour. No autopsy. The physician ran away.

A physician in New Hampshire sends me the details of a case where a patient, who had used moderate doses of the following when necessary, took one-half of it at one dose:

℞.	Chloral hydrate.................	℥ iij.
	Potass. bromid.................	℥ iv.
	Morphiæ sulph.................	gr. vi.
	Ext. belladonnæ.................	gr. iij.
	Aq................................	℥ iv.

Patient was insensible in fifteen minutes, and died with all the symptoms of chloral-poisoning, despite the most approved treatment. He rallied for a time under atropia, but finally sank. This case was reported in the *Boston Med. and Surg. Journal* for April, 1879, and the amount of chloral erroneously made ʒ iij. instead of ℥ iij.

The following letter from Dr. John Bowen, Resident Physician at Riverside Hospital, New York city, explains itself:

"I have known of three deaths which I attribute to chloral. The patients were all cases of chronic mania, in good physical condition, and the drug was given at night to prevent them from making a noise The amount given could not be reliably ascertained It was prescribed by an associate in gr. xx. doses and left with a night nurse, with directions to repeat it in an hour if necessary. In each instance the patient was found dead by a day nurse, on entering the room next morning. In one instance the patient was sitting in a corner of the room. She had evidently been dead for several hours, as the body was cold and stiff. In each of these cases I made an autopsy. There was in every case a large black clot filling the right ventricle of the heart The other organs, including the brain and cord, were perfectly normal to the naked eye, and nothing could be found to account for death. As all of these cases occurred in the service of the same night nurse, and there was an absence of anything else to account for death, the inference is that she gave the medicine in larger doses, oftener, and at shorter intervals than was directed, and the patients becoming quiet, she did not again enter their rooms, and thus they were not discovered until next morning.

Dr. R. Hazlehurst, of Brunswick, Ga., reports (by letter) a case of death from 125 grains, taken without medical advice.

Habitual users of the drug often take an overdose with fatal results. Such a case is reported (by letter) by Dr. F. B. Florentine, of Saginaw, Mich The patient, a lady, in this instance, however, took an enormous dose, 240 grains, probably with the intention of committing suicide. She died. Dr. Florentine was called too late to be of any service.

Death from 130 grains,* and from 125 grains,† sold freely by a druggist to an habitué, is reported; also in unknown quantity with chlorodyne;[*] also another case, quantity unknown.[†]

* By letter.

* Lancet, April 21, 1877.

† Ibid., January 22, 1876.

A medical student was in the habit of taking chloral hydrate in large amount to procure sleep. One night he took ninety grains, from which he died.[‡]

The *British Medical Journal*[§] commenting on the death of Dr. Mercer from chloral, points out that scientific opinion inclines to the view that chloral hydrate, when taken continuously for some time, even in moderate doses, exercises a paralyzing influence over the vaso-motor nervous system, and leads to a failure of the heart's action. This effect may occur suddenly without any serious warning, and it is thought not improbable that in some cases in which it has been assumed that because death supervened, an excessive quantity of the drug had been taken, the assumption has been groundless. It may have been that the ordinary dose had been adhered to, but that the cumulative weakness which its oft-repeated action had induced, ended in the stoppage of the vital processes.

Dr. J. H. Hughes, of St. Louis, Mo., the talented editor of the *Alienist and Neurologist*, writes: "Several cases—not less than five—of sudden death, apparently from heart-paralysis, in persons who had become chloral habituates, and had become accustomed to take the drug *ad libitum*. They were under no physician's treatment at the time."

Dr. A. Atkinson, of Baltimore, reports, by letter, a death from sixty grains of chloral, that occurred in the practice of another physician.

The death-rate from this cause among alcoholic subjects is large, partly, perhaps chiefly, because through ignorance and rashness they take the drug in enormous doses, and partly because, owing to continued debauch the system, especially the vascular, is so weakened as to be unable to withstand the effect of so powerful a drug.

The following is kindly sent me by Dr. A. Ady, of Logansport, Indiana, who clipped it from the *Cincinnati Commercial* of June 13, 1880:

> DEATH FROM CHLORAL.—Ottmer Hill, a printer, who had worked in nearly all the German printing offices in this city, died suddenly, yesterday afternoon, in his room in the third story of No. 21 Woodward Street. He had been a hard drinker, and addicted to the use of hydrate of chloral. Yesterday he swallowed a large quantity at a dose, whether in a fit of delirium or with suicidal intent is not known, but it caused his death.

Dr. A. R. Griffiths, of Oil City, Pa., has sent me a copy of the *Oil City Derrick*, in which is related a death, from an overdose of chloral, in an alcoholic subject who had been on a three weeks' spree. He took about 200 grains at one dose and died.

Dr. Geo. C. Catlett, of the Lunatic Asylum, St. Joseph, Mo., states[||] that he knows of three well-authenticated cases where death ensued from ordinary doses of chloral hydrate in delirium tremens. No particulars are given.

Dr. Hugh Norris reports[¶] the case of a lady, aged forty-six years, who was addicted to the use of liquor. He gave her chloral for hysteria and spinal irritation. She continued its use herself. She took 712 grains in nine days, 260 grains of which was taken within thirty-five hours. Death sudden. Pupils dilated. No abnormality of any organ sufficient to account for death. No congestion of the brain.

In the London *Lancet* for October 20, 1877, is given the case of a drunken woman who took an overdose of chloral and died; and in the same journal of December 7, 1872, another death from 400 grains, prescribed by a druggist, is given. The *Islington Gazette*,[*] May 5, 1872, records the death of a man from forty grains of chloral and forty gtt. tinct. opii., taken after a spree, for the purpose of "tapering off."

Dr. C. T. Jewett, of this city, tells me of the case of a young man aged thirty-five years, suffering from acute alcoholismus. He ordered for him a mixture containing 300 grains of chloral. The patient outwitted his attendants, took the whole amount in fourteen hours' time, getting 120 grains at one dose. He died.

Dr. S. Barruch, of Camden, S. C., writes me of the case of a young man who died from the effects of a dose of eighty grains taken at the end of a spree to quiet nervousness.

Dr. A. P. Brown, of Jefferson, Texas, writes me of three cases of death from chloral in drunkards. Amount taken not known.

Dr. Carroll,[†] of the United States Army, relates in the *Medical Times* the case of an inebriate who took, at one dose, an ounce of chloral with suicidal intent. He died. Autopsy revealed fatty degeneration of the heart and liver.

Dr. James Perrigo, of Montreal, Canada, writes me of the case of an old tippler who is supposed to have died from the use of this drug. He had been on a spree for five weeks, and in trying to stop took a dose of chloral and died.

Dr. William G. Wilson, Assist. Surgeon, U.S.A., Fort Niagara, Youngstown, N. Y., writes me of two cases of death: one, a surgeon in the United States army, who died from a dose of sixty grains. He was a hard drinker. The other was a stout, healthy soldier, who was brought to the post hospital, Fort Brown, Texas, in the spring of 1871, suffering from an attack of delirium tremens. After an emetic had been given and had acted, thirty grains of chloral was administered. It did not produce sleep, but in the course of an hour the patient died suddenly. Dr. Wilson says: "Though the case was reported as a death from delirium tremens, I have always, since I became acquainted with the effects of chloral, been more and more convinced that his death was the result of the drug."

(To be continued.)

NEPHRO-LITHOTOMY is an operation which has recently been successfully performed, for the first time, upon a healthy kidney, by Mr. Henry Morris. The disease was nephritic colic. The presence of a stone was suspected, and incision being made an oxalate-of-lime calculus weighing thirty-one grains was removed from the pelvis of the kidney. The case was especially important, because it showed that a healthy kidney could be cut into without exciting hemorrhage or causing a urinary fistula. The facts established by Mr. Morris will doubtless lead to a more frequent employment of the operation. Even in case the diagnosis proves false, and upon exposure of the kidney no stone is found, no harm need ensue, for the wound readily heals and the counter-irritation produced by it has a beneficial effect.

FACTS AND FIGURES ON CEREBRAL THERMOMETRY.

By R. W. AMIDON, M.D.,

NEW YORK.

During the last few months decided scepticism has been evinced on the part of many medical men and journals as to the value of cranial temperatures as an indication of temperature changes in the underlying brain. This widespread scepticism had its origin in the results of experiments performed by M. François Frank, of Paris, communicated to the Society of Biology of Paris, and published in the *Progrès médical* of Paris, June 5th and 26th, and in the *Gazette médicale* of Paris, July 3, 1880, and quoted in the London *Lancet*, August 21, 1880, the *American Journal of Insanity*, July, 1880, and the *Journal of Nervous and Mental Diseases*, October, 1880.

The experiments referred to were intended to ascertain the exact conductibility of the cerebral envelopes to heat.

The experimenter heated the internal surface of human skulls by placing them over a box of hot water, by passing hot water through a coil of lead pipe laid against the dura mater, or, in living dogs, by the lead coil or injection of hot water into the brain itself.

Knowing the temperature of the water applied internally, he sought by thermometers externally applied to ascertain the exact conductibility of the cerebral envelopes. Through fresh bone 3 mm. thick he obtained in fifteen minutes no rise of temperature by injecting water the temperature of which had risen one degree (C.). 2° internal elevation produced a doubtful $\frac{1}{20}$° externally; 3° internal elevation caused $\frac{1}{15}$° externally; 4° internal elevation caused $\frac{1}{5}$° externally; and 5° caused $\frac{7}{10}$° external rise. He found about the same resistance manifested by the skin, and so we see if we put the dura mater, skull, and scalp together, making in all about 10 mm. of tissue, it would necessitate an internal elevation of 6° (C.) to cause an elevation externally of $\frac{1}{20}$° (C.). He arrived at almost identical conclusions from his experiments on living dogs, and concludes that the cerebral envelopes are such excessively bad conductors of heat that cranial thermometry can hardly be accepted as any indication of cerebral temperatures. Knowing that, if M. Frank's experiments were correct, all our deductions from cerebral thermometry, clinical, pathological, and physiological, were worthless, I resolved to repeat them.

My first experiment, in which I was aided by Professor E. C. Seguin and Dr. W. R. Birdsall, consisted in thrusting a coil of lead tube through the brain against the dura mater of the human head, in injecting warm and hot water through this coil and noting by surface thermometers placed on the shaved scalp any external rise of temperature. It was noted that quite hot water had to be injected for a long time (fifty minutes) before even a small external rise took place.

It was then remarked by Professor Seguin that the lead pipe was an excessively poor conductor of heat, and on examination it was found that while very warm water was circulating through the tube the surface of the tube was hardly warm to the touch. For this reason alone all of M. Frank's experiments with the lead tube ought to be disregarded, for while the conductibility of gold is 1000, that of lead is only 179, and hence entirely unfitted for such an experiment, unless its resistance was calculated.

To obviate this objection I next employed injections of warm water against the *dura mater itself* by means of a glass tube, open at one end and closed at the other by a cork through which passed two pipes. The open end of the tube rested against the dura mater (see Fig. 1); while through one tube warm water was injected by means of a bulb-syringe, from the other the water again escaped. By this means a constant stream of warm water was forced against the internal surface of the dura mater. The temperature of the water injected was denoted by a thermometer lying all the time in the receptacle from which it came, while the external variations were marked by a surface thermometer placed on the shaven scalp directly over the mouth of the glass tube. The results of an experiment in which I was aided by Professors Seguin and Mary Putnam-Jacobi and Doctors A. B. Ball and W. R. Birdsall will be narrated in full detail with an explanatory chart.

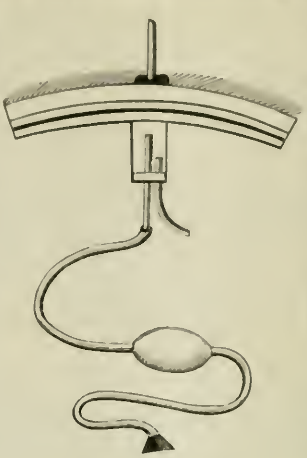

Fig. 1.

The dura mater, skull, and scalp were warmed in a water-bath to the temperature of 95.5° F. (35.3° C.), Then injection of water at the temperature of 117.5° F. (47.5° C.) was commenced. In six minutes the temperature of the injected water had fallen to 117° F. (47° C.), while the surface of the scalp had warmed ¾° F., standing at 96.25° F. (35.7° C.). In the next two minutes the temperature of the water had fallen ⅓°, while the external temperature had risen over ¼° F., and so on till at the end of nineteen minutes the water internally had fallen to 110° F. (43.37° C.), while the external thermometer indicated 97° F. (36.2° C.). At this point the water was allowed to

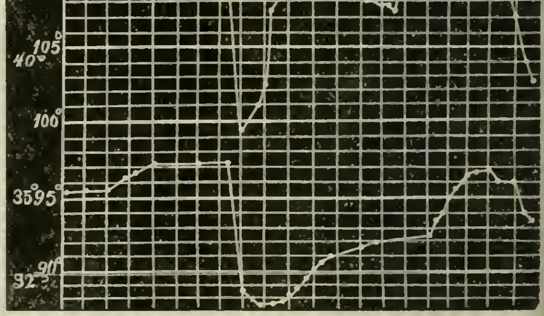

Fig. 2.

cool down to 99.5° F. (37.5° C.), when the external thermometer indicated 88.5° F. (31.5° C.). At this time the water injected was rapidly heated to ascertain the length of time consumed by the heat in traversing the cerebral envelopes. The results of this second experiment are depicted in the accompanying chart, where the higher curve denotes the internal, while the lower denotes the external temperatures which were read by Professor Seguin.

In the first two minutes, while the water rose 1.5° F. the surface fell 1.25° F. At the fourth minute the water stood at 102.5° F., 39.2° C., while the external temperature had fallen another .25° F. (to 87° F., 31° C.). At the *fifth* minute, however, the water having already attained the temperature of 107.5° F. (41.9° C.), the surface temperature began to rise. This rise shows that the length of time consumed by the heat in traversing the cerebral envelopes is about five minutes, which is singularly in accord with most experiments on living subjects. During the next fifteen minutes, while the water oscillated from 111° F. (43.9° C.), to 107.5° F. (41.9° C.), the external temperature gradually rose to 92° F. (33.4° C.), making an external rise of 5° F. (3° C.), to correspond to an internal rise of 8.5° F. (4.5° C.).

At this time, the twentieth minute of the experiment, the temperatures stood—internal, 107.5° F. (41.9° C.); external, 92° F. (33.4° C.); and the water was again suddenly heated in eight minutes, the temperatures reaching—internal, 122.5° F. (50° C.); external, 95° F. (35° C.).

From this time the water was allowed to gradually cool, the external temperature continuing to rise until it attained, four minutes after the maximum internal temperature was reached, the temperature of 97.5° F. (36.4° C.). From that time till the end of the experiment both temperatures gradually sank, the internal much faster, till, at the hundredth minute, the water internally stood at 99° F. (37.25° C.), while the external temperature was 87° F. (30.75° C.).

A careful compilation of this and other similar experiments, not inserted, demonstrates the following facts:

1st. That heat can be transmitted through the dead human cerebral envelopes in very appreciable quantities.

2d. That it is better transmitted when the envelopes are themselves warmed to more nearly simulate the living textures (see first and second part of above experiment).

3d. That the rise of temperature commences externally in from four to eight minutes after the internal elevation, and attains its maximum in from eight to twelve minutes, and that the fall of the two temperatures pursue the same course.

4th. The average of eighty temperatures taken shows a ratio of the internal temperatures to the external of 2 : 1.

This ratio is much diminished when the media are warmed, hence it is natural to suppose that in the warm, living state the ratio would be smaller still.

I take great pleasure in bringing these data, corroborated by such observers as Jacobi, Seguin, Ball, and Birdsall, before the medical public, and contend that these results, carefully ascertained as they were, give our long and tenderly cherished cerebral thermometry a new lease of life.

It is now nine months since I publicly announced my conviction that willed muscular movements caused a rise of temperature on the opposite side of the head. Decided opposition has met this assertion on many sides, but I still assert the *fact*. M. Paul Bert (*Progrès médical*, May 1, 1880) and M. François Frank (*Gazette médicale*, July 3, 1880) assert that they have performed the experiment with complete failure. Let me here insert the tabulated result of an experiment performed in the presence of Drs. Thomas A. McBride and William H. Halsted, at 5 P.M. on Tuesday, December 7, 1880.

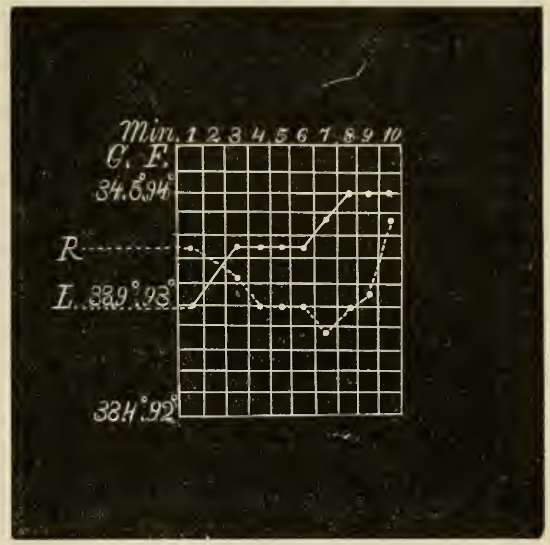

FIG. 3.—Curves of cranial temperatures during willed muscular movements: R, temperature of right, L, of left parietal region.

The experiment was performed in the laboratory of Dr. McBride, and the temperatures were read by him.

The temperature of the room was 56° F. (12.5° C.). The subject was a vigorous boy of sixteen, with close-cut hair. A surface thermometer was placed on each parietal region, 40 mm. to either side of the median line, and 195 mm back from the root of the nose, or 45 mm. behind the bregma. At the expiration of about fifteen minutes the maximum elevation of temperature had taken place and the temperature of the right parietal region was 93.5° F. (34.2° C.), while the left was 93° F. (33.9° C.). At that time vigorous contraction of the right biceps and triceps commenced, and the resulting temperatures recorded every minute are best shown in the accompanying table.

By consulting this chart it will be seen that the temperature on the same side as the movements fell during movements until the sixth minute, and then rose until the ninth minute, when it attained an elevation of ¼° F. higher than when it started.

The temperature on the opposite parietal region, however, rose in the first two minutes, and again from the fifth to the seventh, till at the seventh minute it had attained an elevation of 1° F. higher than it was when movements commenced.

In experiments properly performed I have found the invariable results:

1st. That within the first two minutes a fall of temperature takes place on the same side of the head as the muscular movements.

2d. That this fall continues during the succeeding four or five minutes, and may attain the amount of 1° F.

3d. That at the end of the sixth or seventh minute it begins to rise, and at the eighth to the fifteenth minute will regain its old position, and even, perhaps, a slightly higher one.

4th. That the temperature on the side of the head opposite the muscular movements sometimes slightly falls at first, but on or before the fifth or sixth minute begins to rise, and finally attains a temperature ¼° to 1° F. higher than it started with.

These results are deduced from an immense number of observations, and must be explained as each one sees fit. I myself adduce no theory to explain them. One thing, however, I will say, and that is, if this rise of temperature is produced by cerebral activity (and the time of the commencement of the rise of temperature, after the movements commence, is identical with the time consumed by the heat of water to traverse the cerebral envelopes), the ultimate rise of temperature on the same side may be caused by diffuse radiation from the opposite side—the brain, as is well known, being a good conductor of heat.

A final word as to the cautions to be exercised to make an experiment succeed:

1st. The subject should be strong.

2d. The movements *must be* vigorous.

3d. The hair must be thin or short.

4th. The temperature of the room low (56°-60° F., 12.5°-16° C.) and equable.

◆

Reports of Hospitals.

PRESBYTERIAN HOSPITAL, NEW YORK.

Service of Dr. ALFRED C. POST.

COMPOUND FRACTURE OF THE SKULL—URGENT SYMPTOMS OF CEREBRAL IRRITATION PROMPTLY RELIEVED BY VENESECTION—AMPUTATION OF HIP-JOINT FOR RAILROAD INJURY—PERINEAL ABSCESS—RETENTION OF URINE.

I send you a report of a few cases which came under my care, during my attendance in the Presbyterian Hospital in the month of August. I am indebted to John A. Wells, M.D., late house surgeon, for full notes of the cases included in the report.

Case I.—*Compound Fracture of the Skull.*—Edward Monroe, aged four years, admitted to Presbyterian Hospital, August 2, 1880. One hour before his admission he fell out of a third-story window, striking his head on an iron spike. On admission there was found to be a compound comminuted, depressed fracture of the frontal bone on the right side. There was a small incised wound under the right eye and there was moderate ecchymosis in the same region. There was a pretty copious oozing of serous fluid from the right ear. As the patient was suffering from the shock of the injury, stimulants were administered.

I saw the patient the same evening, and enlarged the wound by a crucial incision, so as to expose the fracture fully to view. With the aid of a rongeur I removed the bony margin overlapping the depressed fragments, which I then removed with forceps from the surface of the dura mater, which was exposed to view and found to be uninjured. The wound was lightly filled with lint soaked in carbolic acid 1 to 40.

August 3d.—The patient is semi-comatose, but can be aroused so as to take nourishment.

August 4th.—Patient remains in about the same condition. Temperature has not risen above 100°.

August 5th.—Stupor has increased. Respiration has become sighing. Convulsions have supervened. Temperature has risen to 105°; pulse, 160. The wet pack was applied, with ice to the head. Five grains sulphate quinine administered per rectum. In half an hour temperature was reduced to 103°, but it soon rose again, and the patient died in convulsions at 7.30 A.M., August 6th.

Autopsy twelve hours after death. Considerable ecchymosis was found in the tissues of the orbit around the right eye. Beneath the crucial incision, through the integument, there was an irregular opening in the frontal bone of the size of a silver half-dollar. When the scalp was removed, there was found effusion of blood behind and above the middle of the right parietal bone. The sinuses and veins of the dura mater were fully distended with blood, and contained a discolored coagulum which could be drawn out in long strings. With the removal of the dura mater there was an escape of bloody serum around the opening in the frontal bone. Between it and the dura mater there were a number of small fragments of bone, but there was no marked injury to the membranes. All over the convexity of the right hemisphere was a layer of coagulated blood of very dark color. The vessels of the pia mater and arachnoid were deeply congested, but there was no evidence of actual inflammation at any point. When the brain had been removed, considerable bloody fluid remained behind in the spinal canal and the posterior fossæ. Around the right jugular foramen was a large mass of dark coagulated blood. Sections through the brain-substance showed the whole of the brain in a state of deep congestion, the puncta vasculosa being very prominent, and blood and little plugs of coagula oozing from many of them. Each lateral ventricle contained about an ounce of bloody serum. An irregular fracture extended from the opening in the frontal bone backward and inward, across the orbital plate of the frontal and ethmoid bones, terminating in the median line at the junction of the ethmoid and sphenoid bones. Another fracture extended inward and backward through the outer extremity of the lesser wing of the sphenoid to the junction with the greater wing, thence backward and outward across the great wing to the middle of the squamous portion of the temporal bone and the middle fossa of the skull, and thence through the petrous portion of the temporal bone, and finally terminating in the jugular foramen. The length of the fracture, following all its curves, was about eighteen centimetres.

In reviewing this case it is proper to observe that although the early symptoms were not of extreme severity, yet the oozing of serous fluid from the ear rendered it highly probable that there was a fracture through the petrous portion of the temporal bone, and suggested the probability of a fatal termination.

Case II.—*Concussion of the Brain—Dislocation of Head of Femur on Dorsum Ilii—Urgent Symptoms of Cerebral Irritation promptly relieved by Venesection.*—Walter Naughton, aged thirty years; married; conductor on elevated railroad; admitted to Presbyterian Hospital, August 28, 1880. He is a man of very nervous temperament, but of strictly temperate habits. Half an hour before his admission he had sustained a very severe blow in the right temporal region, by striking his head against one of the pillars of a station on the elevated road. The train was running at full speed at the time, the patient leaning over the guard-rail. The force of the blow was sufficient to cause him to turn a complete somersault, landing him on the platform. The left hip struck against the guard-rail. While the patient was being brought to the hospital he had a convulsion with free vomiting. On admission, his pupils were found to be normal, but there was very marked cerebral irritation indicated by extreme restlessness, jactitation, and impatience of restraint. Blood oozed freely from his right ear. There was vomiting of food, and afterward of blood. The temperature in the axilla was normal; pulse, 100, and full; surface covered with clammy perspiration. It was impossible to arouse him to an intelligent perception of surrounding circumstances. The left hip was found to be dislocated on the dorsum ilii. The dislocation was readily reduced by Reid's method without the use of an anæsthetic. The knees were tied together, to guard against a recurrence of the dislocation. Five hours later, viz., at 7 P.M., reaction was established. Temperature, 100°; pulse, 112; patient was very delirious. An ice-bag was applied to the head. A full dose of chloral hydrat. and bromid. potassii was administered by the rectum. One drop of croton-oil was placed on the back of the tongue. At 9 P.M., temperature, 101°; pulse, 112. At midnight, temperature, 102°; pulse, 120; wild delirium; head shaved; chloral hydrat. and bromid. potassii repeated per rectum.

On the following morning, at 10 A.M., temperature, 103¾°; pulse, 120, and full; noisy delirium. Considerable force was required to prevent the patient from throwing himself out of bed. Soon after this I saw the patient for the first time, and opened the median cephalic vein of the right arm, taking from the patient twenty fluid-ounces of blood. The violence of the delirium was abated at once in a marked degree. Chloroform was cautiously administered by inhalation, until the patient was entirely tranquillized. Two hours after the venesection the temperature had fallen to 100°; pulse, 112. The delirium had completely subsided, and the patient was sleeping quietly. The oozing of blood from the right ear continued for thirty-six hours after the injury. During the period of seventy hours following the venesection the patient was free from delirium, and the temperature continued below 100°. At the end of that time he had a severe chill, followed by a rise of temperature to 103°, with a full pulse of 120, and active delirium. Phlebotomy was again resorted to, and about ten fluid-ounces of blood were removed. The delirium at once subsided, and, within an hour, the temperature was reduced to 100°, and the pulse to 90 beats, the patient sleeping quietly for several hours. After this time there was no further rise of temperature. From the first of September the treatment was directed by my colleague, Dr. Briddon. On the 5th of September a mixture containing iodid. potassii, gr. xv., tinct. belladonnæ, ♏x., ext. fluid secal. cornut., ʒ ss., and bromid. potassii, gr. x., was directed to be given once in four hours, and there was gradual improvement under its use. After a few days the belladonna and the bromide were omitted from the prescription. Blisters were applied behind the ears at intervals of a few days. One month after his admission the patient was discharged, perfectly rational, and in excellent general condition. In the review of this case it appears to me that the favorable result is largely to be ascribed to the abstraction of blood, which on each occasion was promptly followed by a marked abatement of the cerebral irritation and of the febrile excitement. There is scarcely any class of cases in which venesection is better tolerated, and in which it affords more relief than in traumatic hyperæmia of the encephalon.

There is another feature of interest in this case, viz., the oozing of blood from the meatus auditorius for the period of thirty-six hours after the injury. A slight flow of blood from the auditory canal for a short time after an injury of the head, is not to be regarded as a grave symptom. But when the sanguineous discharge is profuse, and especially when it is long continued, it strongly indicates the probability of fracture through the petrous portion of the temporal bone, and unfavorably affects the prognosis.

CASE III.—*Compound Comminuted Fracture of the Femur and Tibia—Amputation at the Hip-joint—Death from Shock.*—Delia Benson, aged twelve years. Admitted to Presbyterian Hospital, August 8, 1880. Her parents represented that she had enjoyed good health until the time of the injury. An hour and a half before her admission she had fallen from the front platform of a Second Avenue horse-car, the wheels of which passed over her left lower extremity. When she was brought to the hospital she was suffering from the shock of the injury. The hemorrhage was very slight, and venous. Pulsation could be detected in the posterior tibial artery. The pulse at the wrist was quite distinct. The left lower extremity was terribly mangled. There was a compound comminuted fracture above the middle of the femur, a T-shaped fracture through the articular end of the same, extending into the knee-joint, and breaking off the articular cartilages. There was, in addition, a depressed compound fracture of the upper third of the tibia. The soft parts of the thigh were crushed and mangled from a hand's breadth below the groin down to the knee, and the integuments of the upper part of the leg were also involved in the injury.

I saw the patient in the evening, a few hours after the injury, and deemed it impossible to save the limb. The thigh had been bandaged firmly just below the groin to arrest the hemorrhage. I did not think it safe to remove the bandage, nor to leave it in place until morning. The injury extended so high up that the only feasible operation seemed to be amputation at the hip-joint, and there was not room to make the anterior flap of the usual dimensions. I performed the operation by the method recommended by Prof. Wm. H. Van Buren, introducing a sharp-pointed knife just below the anterior superior spinous process of the ilium, and bringing out the point of the instrument through the integument of the upper and inner part of the thigh near the anus, cutting downward with the edge of the knife very near the anterior surface of the thigh-bone, until there was sufficient space for my assistant, Dr. Wetmore—who aided me in the absence of Dr. Wells, the house surgeon—to introduce his hand into the wound above the back of the knife, and behind the great vessels, which he then efficiently compressed between the hand in the wound and his other hand in front of the integument. When Dr. Wetmore notified me that the vessels were under his control, I turned the edge of the knife forward and completed the anterior flap, which I was obliged to make considerably shorter than usual. The flap was then turned upward, and ligatures were applied to the femoral and profunda, which pulsated distinctly, but from which there was no escape of blood. I then opened the capsule of the joint, divided the ligamentum teres, and made a posterior flap a little longer than usual, to make up for the deficiency of the anterior flap. There was no bleeding from the vessels of the posterior flap, and the pulse was imperceptible at the wrist. A hypodermic injection of brandy was at once administered, an enema containing brandy was thrown into the rectum, and the vapor of nitrite of amyl was administered by inhalation, but the patient did not rally, and it soon became evident that the patient had died from the shock of the operation superadded to that of the injury. No autopsy was allowed.

Case IV.—*Deep Perineal Abscess—Retention of Urine.*—Paul Laval, watchmaker, aged thirty-two years, a native of Switzerland, married, was admitted into the Presbyterian Hospital, August 29, 1880. He had had two attacks of gonorrhœa. The first, two years before his admission, was followed by retention of urine. The second attack, a year afterward, was followed by gleet, with a diminished and twisted stream. Ten days before his admission, after exposure to cold, he had a severe rigor, followed by high fever, with pain and heat in front of the anus, and he could only void his urine by drops. Three days before his admission a steel sound, twenty-four millimetres in circumference, was passed through the canal with difficulty, followed by slight hemorrhage from the urethra. On admission to the hospital, the patient had not passed any urine for sixteen hours. Dr. Wells, the house surgeon, introduced a soft, flexible catheter without much difficulty, and drew off sixteen ounces of high-colored albuminous urine. There was decided tumefaction in the perineum, with localized heat and throbbing pain. A mercurial cathartic was administered, followed by an anodyne. On the following morning I saw the patient for the first time. I introduced steel sounds up to thirty millimetres without difficulty, and there was nothing to indicate that they did not pass freely into the bladder. I then passed a large silver catheter, but no urine came away, but there was an escape of half an ounce of thick, ropy pus, tinged with blood. Tepid water injected through the catheter came away clear. With some difficulty a smaller silver catheter was passed into the bladder, and eight ounces of high-colored urine were drawn off. Several hours later the patient passed urine without any difficulty, and the perineal pain was completely relieved. The patient was discharged on the following day, and he returned a week later with the report that he had experienced no further difficulty in micturition. All signs of inflammation in the neighborhood of the neck of the bladder had disappeared.

Singing as a Cause of Uterine Disease.—Dr. Clifton E. Wing publishes in the *Boston Medical and Surgical Journal* some very interesting cases relating to this subject. He had several lady-patients, who came to him for uterine trouble, and all voluntarily asserted their belief that the complaints were due to the "abdominal method" of singing which they had been trying to learn. This consists in the cultivation of diaphragmatic respiration at the expense of thoracic. It naturally causes great pressure to be put upon the abdominal organs. One Boston teacher boasts that by "proper practice" such power may be acquired that if the person be placed back against the wall, and a full-sized piano be moved up against the retracted abdomen, the latter, by the "abdominal method," can be so forcibly expanded that the piano will be pushed rapidly away. The new method adds greatly to the power of the voice. Dr. Wing found in the cases examined that it had caused a retroflexion or retroversion, with various coincident ills. He believes that in the "abdominal method" as now practised we have a fruitful source of uterine displacement.

Progress of Medical Science.

Hemorrhage caused by the Acid Nitrate of Mercury.—Dr. Charles B. Nancrede reported to the Philadelphia County Medical Society, September 8, 1880, an interesting case of hemorrhage caused by the acid nitrate of mercury, which illustrates the disadvantage of applying this remedy to all sores upon the penis. He had been called in consultation to see the case, and found an alarming hemorrhage from the dorsal vessels of the penis, which came on after an application of this caustic. He was obliged to secure both dorsal arteries by acupressure. There was subsequently some return of the hemorrhage, but it was speedily checked. Sloughing also followed, which opened the urethra, and required a plastic operation. The patient finally recovered, and has had a healthy child, so that in all probability the first lesion was not syphilitic.—*Philadelphia Medical Times*, October 9, 1880.

A Celluloid Nose as a Substitute for Ineffectual Rhinoplasty.—A dentist in Bamberg, Dr. V. Blumm (*Bayer. aerztl. Int.-Blatt*, 1880), recently modelled a celluloid nasal organ for a patient who had lost his nose in consequence of lupus. Rhinoplasty had been tried by Thiersch, but the absence of the nasal cartilages made the operation an unsuccessful one. The nasal passages were kept open by the introduction of goose-quills, and the patient was in a distressing condition. A plaster-of-Paris model of the parts was first made, and then a wax nose fitted to the same. This was afterward worked in celluloid, and two little silver canulæ substituted for the goose-quills. By a hooklet the celluloid nose was attached to a pair of spectacles. This apparatus is cleaned twice daily, and occasions so little inconvenience that the patient does not even remove it at night.—*Memorabilien*, August 31, 1880.

Elephantiasis of the Leg treated by Elastic Bandaging.—At a meeting of the Clinical Society of London, Dr. Stephen Mackenzie reported a case of elephantiasis which showed the good effects of elastic bandaging. Patient, male, aged thirty-three years, worked always as a farm laborer in Ireland, and was healthy until present disease. Never had syphilis. Had never eaten largely of fish. Ten years ago sustained an injury to the leg, which was much bruised and swollen. About three years after the accident the leg was noticed to be larger than its fellow, and from that time to his coming under observation the limb continued to enlarge. About four times a year, with a certain degree of regularity, the leg would become acutely worse; for a few days he would suffer from nausea, headache, and shivering, and then the leg would become sore and painful, feeling extremely hot, and looking red and steaming. After remaining in this state for about a week the surface of the leg would begin to discharge a clear fluid of offensive smell. When admitted into the London Hospital, September, 1879, the limb was enormously swollen, presenting several large lobulated masses of œdematous tissue, and the surface was covered with abrasions of the cuticle and papillary elevations. There were no enlarged glands. No changes in the blood or urine. The patient was placed in bed and Martin's bandage firmly applied to the leg from the toes up to the thigh. He was kept in bed, with the exception of being allowed to go into the garden for one hour a day. The diminution in the size of the limb from the time the rubber bandages were applied was almost uninterrupted and very remarkable. All the lobulations subsided, and the papillary elevations disappeared. A good deal of fluid exuded from the cuticular abrasions, and the decrease in the limb appeared to be proportionate to the fluid discharged. The patient had no inconvenience from the treatment. Whilst the case probably differed in its origin from the tropical ones, from which it differed also in the absence of filariæ in the blood, the disease reached almost as high a grade as the elephant-leg of Barbadoes or India. It was found that the swelling recurred when the bandages were removed, so that it is probable that the bandages will have to be worn permanently.—*Medical Press and Circular*, October 13, 1880.

On the Removal of Uterine Tumors by Abdominal Section.—T. Spencer Wells, in his address delivered in the Section of Obstetric Medicine, at the annual meeting of the British Medical Association in Cambridge, August 13, 1880, introduced a discussion on the removal of uterine tumors by abdominal section, and stated that since the delivery of the Hunterian Lectures at the College of Surgeons he has operated antiseptically, and has had ten cases of removal, with three deaths and seven recoveries; also five cases of incision and puncture, all recoveries; or three deaths in fifteen operations. His whole experience amounts to sixty cases: thirty-four of removal, with eighteen deaths and sixteen recoveries; twenty-six of incomplete operation, with only one death. The smaller mortality since adopting antiseptic precautions is certainly remarkable. In these operations the risk is very small, indeed, if the attempt end in incision and puncture only, and it may be expected to become much smaller as experience increases and the details of the different steps of the operation are more carefully studied and more frequently practised. He insisted strongly on the advisability of uniting divided edges of peritoneum to each other. When the abdominal wound is united the peritoneal edges should be brought together, to insure the complete closure of the peritoneal cavity, and prevent the admission of fluids oozing from wounded muscle, fat, and cellular tissue, and also to prevent contact of intestine and omentum with anything more than peritoneum. He strongly advised, also, that the peritoneal edges of the divided uterine wall should be brought together by sutures along the whole extent of the gap. Schröder, of Berlin, uses two rows of sutures: first, one row which closes the mucous surfaces of the uterine cavity, and is left to pass away downward by the vagina; and a second one, which brings the peritoneal edges of the fundus and broad ligament together. Hegar, of Freiburg, has returned to the extra-peritoneal treatment, and is especially careful to close the peritoneal edges of the lower part of the opening in the abdominal wall very accurately around the peritoneal edges of the uterine stump. Wells prefers the intra-peritoneal treatment, provided the edges of the peritoneum are accurately brought together. He had recently removed a large fibro-cystic tumor which involved the fundus and part of the body of the uterus. The patient was over sixty years of age. The operation proved successful, which was due principally to the stitching together of the peritoneal edges of the divided uterine wall, an opening being left for a little oozing of blood through the vagina.—*British Medical Journal*, September 4, 1880.

Foreign Bodies in the Rectum.—The danger of introducing foreign bodies into the rectum as a means of arresting the discharges of dysenteric inflammations is exemplified by the following cases. M. Verneuil extracted a foreign body from the rectum under the following conditions: An old soldier, tormented by the frequent action of the bowels due to a chronic dysentery, had adopted the habit of blocking up the rectum by means of a tampon, in the centre of which he placed a piece of wood. Having neglected on one occasion to envelop the piece of wood in linen, it ascended into the rectum, and he was unable to extract it. When seen by Mr. Verneuil the piece of wood was out of reach of the finger in the rectum, but could be felt in the iliac fossa. In order to reach it he was compelled to perform linear rectotomy, which he did after the method of Lister, and succeeded in saving his patient. Another case, recorded by Dr. Briggs, of Nashville, is that of a man who introduced into the rectum a large wineglass, which was removed under an anæsthetic. The glass was found high up in the rectum, the rim being firmly impacted in the mucous membrane. The posterior wall of the gut was considerably lacerated, but not perforated, where the glass had been imbedded. There was no hemorrhage immediately after the operation, but subsequently the patient lost a considerable quantity of blood, and he succumbed, thirty-six hours after the operation, to exhaustion from loss of blood and diarrhœa.—*Nashville Jour. of Med. and Surg.*, October, 1880.

Operation for Hepatic Echinococcus by Thoracic Incision.—At the eighth meeting of German Surgeons, Dr. Israel presented a patient, aged thirty-two years, on whom this operation had been successfully performed. Abdominal interference being rendered impossible on account of the pushing up of the diaphragm and the high position of the hydatid cyst in the convexity of the liver, the following plan was adopted: the pleural cavity was first opened and a portion of the sixth rib excised. The costal and diaphragmatic pleuræ were here in close apposition, so that there was little danger of air entering the cavity. Seven days later the diaphragm was incised, the cut including its peritoneal covering. After nine days the serous coats of the diaphragm and liver were found firmly united, and then the hydatid sac was opened and a silver drainage-tube inserted. In ten weeks the patient was cured. The author mentions that traction of the hepatic cicatrix occasions the characteristic reflex symptom of pain in the right shoulder.—*Memorabilien*, August 31, 1880.

Multiple Cutaneous Gangrene due to Cachexia.—In 1878, Prof. Simon first called attention to this comparatively rare disease, which for the most part affects children of various ages, and has a malignant character. Dr. Eichhoff recently observed a case of this kind at the Breslau clinic for cutaneous and syphilitic diseases. The child, three years old, was first seen in April, and was then suffering from extensive eczema of the face, breast, and back. Constitutional symptoms were not marked at this time, and the eczema rapidly yielded to appropriate treatment. In May the child was again brought to the clinic, when its general health was found to be much depreciated. The back had been covered with dark red patches, the largest about the size of a millet-seed. Vesicles soon appeared above these patches, but they rapidly collapsed, leaving ulcers, which soon became gangrenous. The sloughing extended deeply down into the subcutaneous connective tissue. Local and constitutional treatment caused these sloughing ulcers to heal, with cicatrices resembling those of variola. Some time after this a corneal ulcer developed, and simultaneously with its appearance the head became affected with gangrenous ulcers. The latter slowly healed, leaving deep cicatrices. A second exacerbation occurred in June, and again a corneal ulcer was one of the complications. The ointment, applied locally, consisted of 15 parts each of camphor and myrrh, with 100 parts of vaseline. The pathogenesis of this affection was said to resemble that of ordinary bedsores. The appearance of the corneal ulcers was explained by the depreciation of the child's general health and insufficient *vis à tergo.* —*Deutsch Med. Woch.*, August 21, 1880.

Note on the Evolution of the Gastro-Intestinal Glands.—In a communication to the section of zoölogy of the *Association française pour l'avancement des sciences*, Dr. Condereau makes known the results of his researches on the evolution of the gastro-intestinal glands. From a physiological point of view he concludes that alimentation should correspond to the digestive power, which depends upon the degree of development of the gastro-intestinal glands, and not upon the age of the being.

From an anatomical standpoint the following conclusions are given: 1. In the fœtus the gastro-intestinal mucous membrane is thrown into folds covered with cup-like epithelia. During the progress of gestation these folds increase in number and extent, thus intercepting, as it were, certain spaces. The form of the latter resembles more and more that of glands, and in fact the glands originate in this way. 2. It is only some time after birth that the glands are definitively formed. 3. At birth the glands are still very imperfect. The secreting tubules, agglomerated by the surrounding tissue, are as yet quite indistinct, but the epithelium is not so clearly marked as in the fœtus or in the newly born animal. 4. The glands in general, and especially those of the stomach, gradually grow larger until adult age is reached. During their growth and development considerable variations occur in the relative size of their constituent elements. This proportion may be regarded as definitely established about the epoch of weaning. 5. During this period the epithelia undergo remarkable transformations. The epithelium of the mucous glands, at first very voluminous, gradually grows less conspicuous, and at length about the period of weaning attains its normal and permanent size. 6. At birth, properly speaking, the pepsin-cells do not yet exist. The cells are very minute, and their protoplasm is hardly granular. Gradually, however, these cells grow, and their contents become more and more granular. The evolution is completed at about the period of weaning, although even then the cells are rather less granular than at adult age. About the end of the first third of the period of their evolution the pepsin-cells first begin to bulge out laterally from the gastric tubules.—*La tribune médicale*, August 29, 1880.

The Elastic Ligature in Fistula in Ano.—Dr. A. W. Perry has found the elastic ligature efficient in the treatment of fistula in those patients who dread the use of the knife, and records two successful cases in the *San Francisco Western Lancet*, October, 1880. Solid rubber cord, one-eighth of an inch in diameter (elastic ligature), was used, and was pulled with a force of four ounces. In one case the patient had suffered from the fistula for many years; its external opening was three-quarters of an inch from the anus, and the internal opening one and one-half inch above. This cut through in six days. The ligature was tightened on the third day. In the other case, the fistula was an inch from the anus, and entered the rectum two inches above. This was divided by the ligature in seven days. In neither case was there any inconvenience beyond a slight smarting the first day the ligature was tightened. To perform the operation a flexible silver probe, with an eye in one end, armed with silk, is passed through the fistula into the rectum and out through the anus. By means of the silk the elastic cord is pulled through, and the ends are tightened by a pull which would raise four ounces, and are then tied together close to the skin with silk. If the ligature divides the tissues slowly, they will heal up behind it. The after-treatment consists in the administration of Friedrichshall or Hunyadi Janos water, or a saline cathartic in the morning before breakfast, and immediately after the evacuation an enema of warm water or infusion of mallow-root or linseed. The parts are thus prepared for healing. For want of such treatment one often sees the cuts for fistula remain unhealed an indefinite time.

Fatal Ulceration of Duodenum following Local Application of Hot Water.—J. R. Greenwood, M.R.C.S., reports, in the London *Lancet*, August 21, 1880, a case of fatal ulceration of the duodenum, produced through scalding by hot water used as a hemostatic. The patient had an epitheliomatous growth on the penis which invaded that organ as far as the pubes, and amputation was resorted to as a means of relief. Twenty-four hours after the operation there was profuse hemorrhage from the wound. Styptics were applied, but without effect. The condition of the patient rapidly became critical, and the doctor finally employed the method advocated by Mr. Keetley, of St. Bartholomew's Hospital, viz., sponging the bleeding surface with hot water. By this means the bleeding was arrested. The patient, however, passed a bad night, complaining of pain and uneasiness in the part, which wore a very unhealthy appearance. Early next morning he was seized with an acute pain in the abdomen, accompanied by vomiting, feeble pulse, cold extremities, and anxious countenance; the bowels were confined, and peritonitis became well marked. Temperature steadily rose to 106.3°. Death occurred within a few hours. *Autopsy* revealed the following: heart hypertrophied —weight, eighteen ounces; valves healthy. Lungs congested and œdematous. On opening the abdomen, a large quantity of opaque, greenish, stinking fluid escaped; a large, pale clot was seen lying near the duodenum, and on pulling it aside a rent through the peritoneum was discovered, near the head of the pancreas. On opening the duodenum a deeply indented, elongated ulcer, with a well-defined margin, about an inch long and half an inch broad, was seen. All the coats of the intestine were destroyed, so that the pancreas formed the base of the ulcer. The visceral layer of the peritoneum was everywhere vascular and opaque, the parietal layer being coated with soft lymph. The rent into the peritoneal cavity was close to the margin of the ulcer. The duodenal complication was attributed to scalding by the hemostatic used, which also caused the sloughing of the wound.

The Treatment of Hip-Disease.—Dr. E. H. Bradford has recently given a very fair statement of the results of the various methods of extension, and cites cases occurring in his own practice by way of illustration. By experiments on the cadaver he was unable, with an extending force of one hundred and fifty pounds, to produce "distraction" (a term introduced by Volkmann) or separation of the bones forming the joint. On the body of a full-term fœtus, however, even with one pound, he was able to separate the bones one millimetre. The explanation lay in the fact that the fibro-cartilaginous collar which surrounds the head of the femur in the adult is absent in the newly-born child. If the relief which is given by extension be due to actual separation of the bones, it must be in cases wherein the fibro-cartilaginous collar is loosened by the disease, and in the early stages this is presumably not the fact; it, as a rule, is due to the control of the muscles. There are instances, he cites, where extension does not give relief, and is even uncomfortable. This he thinks might be explained on the supposition that extension relieves muscular spasm and the pain caused by the undue pressure of inflamed surfaces of bone, but not that due to inflamed synovial walls or the distention of a synovial cavity; and he adduces in support of this the experiments of Schultze, who found that extension of a distended joint brought about an increase of the intra-articular pressure, but that an extension of six pounds continued for four or five days effected a diminution of this pressure, either by relaxing the ligaments or bringing about an absorption of the fluid through an increase of the pressure. As to the weight and pulley, it is not a thorough means of extension, and is incapable of preserving the parallelism of the limbs, an indication so important that if neglected a cure leaves the patient as much of a cripple as an amputation would.

While the "physiological method" advocated by Dr. Hutchison, meets certain indications, it cannot be relied upon in all the phases of the disease. As a means of extension it is imperfect for the reason that it is efficient only when the patient is upright. It is not certain to protect the joint from jar. He reports seven cases treated by this method, in four of which the stiffness and tension of the adductors remained the same after from six to eight months. In one, Case XI. of the series, the cure at the time of the report seemed perfect (only three weeks after treatment was suspended). The fact that there had been one or two cures and relapses in this case makes the final result still questionable. Case XII. is not complete, and the sex (female), taken in connection with the age, twenty years, makes one strongly suspect a neurosis of the hip. Case XIII. is similar to Case XII. These results compare very unfavorably with those given by Dr. Hutchison in his recent work. Dr. Bradford has been unsuccessful with the method of Hugh Owen Thomas, of Liverpool. The author prefers, for the majority of the indications, the long splint employed by Dr. C. F. Taylor, although this does not protect the joint from a jar, and is not a perfect means of fixation. He reasons that, inasmuch as it has been clearly demonstrated by Volkman (*Klinische Vorträge*, 168, 169) that in many cases of hip-disease the lesion is, in the early stages, a caseous degeneration or local tuberculosis in the epiphysis of the head of the femur, and that the joint is not primarily affected, it is certainly as bad treatment to subject all cases of hip-disease to long confinement as it would be to confine patients with phthisis in order to prevent bronchitis. His conclusions are that the treatment should be based neither upon any one method, nor upon the use of any splint. At different times and in different cases, one condition, and the consequent indication for treatment, may be more prominent than another. The greatest danger is from destructive changes of the bone, and not from the synovitis; and hence, jar upon the inflamed tissues, when caused either by locomotion or by muscular spasm, is especially to be avoided, and this must be done until recovery has so far taken place that there is no possibility of relapse. This requires a long time, during a large part of which motion may not be injurious. The stage when jar must be prevented is longer than the stage when rest is required.—*The Boston Medical and Surgical Journal*, Nov. 11, 1880.

Catarrhal Gland-Fever is the name proposed by Dr. Hugo Engel, of Philadelphia (*Medical and Surgical Reporter*, November 13, 1880), for an affection which seems to be far from rare, but has not been described in any of the systematic works on internal medicine or books on surgery. He has seen nine cases, one of which was in consultation with Dr. S. D. Gross. There are but few complaints which, like the one in question, experience so similar a course, viz.: A person usually in perfect health, after an exposure to cold and damp, has chilly sensations, followed by increased temperature, fever, and a rapid pulse. Digestion is disturbed; bowels are sluggish; urine highly colored and very acid. From the very beginning of the complaint the patient has pains all over, but especially in or near the inguinal regions, and most of the superficial inguinal and a few of the superficial abdominal glands on both sides of the body are enlarged and painful; these become painful and the integument over them is reddened. All these symptoms continue for about three to five weeks, when one or two of the glands last mentioned suppurate. Then the fever and the digestive disturbances commence to decrease and then disappear, leaving the patient in a debilitated condition, from which he slowly recovers. The weakness in the lower extremities is especially apt to remain for a long time. While the glands on both sides are affected, only those on one side are apt to suppurate. No other glands of the body, except those alluded to, are ever attacked in this complaint. The disease cannot be mistaken for any other. The fever and the acute beginning, as well as the history of the case, distinguish it from simple scrofulous enlargement and suppuration of glands. The fact of the exposure and the number of glands involved separate it from the bubo of syphilitic or blennorrhœic origin. In lymphadenoma the number of white corpuscles is increased, which is not the case in the disease here described. There is no abortive treatment of any kind. The disease undoubtedly belongs to the domain of internal medicine. It seems to attack only adult men, and affects a patient but once. Almost without warning the disease will incapacitate an active man for at least six weeks for any work. As the disease will run its course we can only try to prevent suppuration of more than one gland, to hasten absorption of the morbid products of the others, and to accelerate convalescence. The moment we attack the glands more vigorously, to hasten either suppuration or absorption, we only prolong the case. In this disease the doctor as well as the patient must have patience. Iodide of potassium and iodoform are useless; mercurial preparations do harm; japorandi or other diaphoretics debilitate without any benefit, and a tonic treatment with iron, etc., from the beginning, only disturbs digestion the more.

Cholera is very prevalent in British Burmah.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, December 25, 1880.

THE PATIENT'S CONSENT TO AN OPERATION AND THE SURGEON'S DISCRETION.

The recent suit for malpractice against Dr. Henry D. Noyes, of this city, involved not only a point of great interest to ophthalmologists, but also to general surgeons. The suit was brought as a test of the right of a surgeon to alter his plan at an operation without again consulting the patient. The facts brought out in the trial were substantially as follows: The plaintiff was a young man, a native of Massachusetts, who had membranous cataract in both eyes, and who, on November 6, 1876, presented himself for gratuitous treatment in the service of Dr. Noyes, at the New York Eye Infirmary. A cursory examination was made of both eyes, showing the left to be the better of the two as regarded cataract. The patient was advised to have both eyes operated upon, and one at a time. The plaintiff claimed that when this suggestion was made, he replied: "I only want an operation on the right eye. I don't think I shall ever have anything done to my left eye." The mother says she stated that under no circumstances would she permit the left eye to be exposed to any risk, as her son depended solely upon it for sight. His father swore that he emphatically dissented' from the doctor's proposition. After the expression of opinion regarding the advisability of successive operations, atropine was used, the patient and his friends retired for nearly an hour, when opportunity was offered for consultation. At the end of that period Dr. Noyes examined both eyes with the ophthalmoscope and oblique illumination, and deliberately repeated his decision regarding the operations, when no dissent or reply was made by the patient or his friends, they remarking that if they concluded to have the operation performed they would return on the following Friday. They did return on that day, and Dr. Noyes' statement of the succeeding events was to the effect that the young man placed himself upon a table and was given an anæsthetic. Just before becoming insensible the patient raised his hand and placing it upon his right eye said, "This eye, doctor." Proceeding to operate on the right eye, Dr. Noyes found that the pupil was filled with a material which consisted of vascularized false membrane, mingled with a plug of unabsorbed cataractous material. The instrument used—a double-edged needle—not only penetrated this intra-pupillary substance with unexpected difficulty, but produced bleeding at the periphery of the iris, and altogether gave such an unfavorable outlook for the future of the eye that the operation was abandoned. Dr. Noyes claimed that nothing but a harmless exploration was made of this eye--in other words, that no operation had been performed upon it. Consequently, he thought it his duty to operate on the other eye, inasmuch as he concluded that he would be keeping his promise not to operate on both eyes at once, and would give the patient a chance for improved sight.

Accordingly the ordinary two-needle operation for membranous cataract was performed on the left eye, without accident, and was perfectly satisfactory. The patient, subsequent to the operation, and while being led to the ward, remarked to his father that both eyes had been operated upon, and neither he nor his father entered any remonstrance. The defendant saw the patient on the following Sunday, and was alarmed and astonished to find a very serious inflammation of the iris and ciliary body of the left eye. An incision was promptly made through the margin of the cornea, the plastic exudation removed by the iris-forceps, and a small upward iridectomy was performed, with the immediate result of relieving pain. But the inflammation continued, and the eye was finally destroyed by suppurative irido-cyclitis. It was not until ten days had elapsed from the time of the operation, and when the eye was lost, that the mother, who was the constant attendant upon the patient, made any intimation that the left eye should not have been operated upon. Dr. Noyes replied to her that he had performed the operation in good faith, and that the bad result, in his experience, was against all rule. Three weeks subsequently to the operation, and while the patient was still in the infirmary, the father openly accused Dr. Noyes of violating his agreement by operating on the left eye without due authority, and this Dr. Noyes at once emphatically denied.

The suit was subsequently brought for $10,000 damages. The skill in the performance of the operation was, as might have been expected under the circumstances, not questioned, the whole point of the case turning upon the fact whether or no the surgeon was entitled to alter the order of his operations without additional and express permission from the patient or his nearest kin. The defendant urged that the silence of the parties when he proposed to operate first upon one eye and then upon the other was equal to acquiescence. Upon this implied authority Dr. Noyes claimed that it was within his discretion to change his opinion as to which eye he should operate on first after he had begun. In this he was ably supported by the expert testimony of Drs. Loring, Roosa, and Gruening, and Dr. Miller, of Providence, who had examined the patient there. They testified that such action was entirely within the scope of discretion ordinarily assumed by surgeons in such cases.

Judge Russell stated in his charge that he could find no records of a similar case; that it was an extraordinary one, in that it brought up the question as to what constituted legal permission—whether or no there was reasonable ground for the doctor to assume that his proposition was consented to. But the point in law which has perhaps as much importance to the surgeon as any other brought out by his honor is the charge that the patient under the excitement of an impending operation was not competent to revoke any authority previously given regarding the character or extent of the operation. The jury disagreed, but brought in a verdict of ten to two in favor of the defendant.

As has been said, the plea of absence of authority to perform an operation is a new one in medical jurisprudence, and, as it will doubtless be urged again, it behooves surgeons to be on their guard accordingly. In the present case Dr. Noyes believed he had the requisite authority and acted in good faith, but it must be confessed that said authority was given by acts rather than by words. No question of want of skill was raised, no one doubted the motives of the operator in giving the patient the best chance in his power, no claims were made that any special risk was run in the performance of an operation on the left eye—in fact, the disastrous result was against all rule and expectation; still, in the light of the present experience in the case, it is safe to say that neither Dr. Noyes nor any other careful man will hereafter be satisfied short of a positively expressed permission from the patient to be operated upon. Under the circumstances of a possible suit for damages there should be no exception to such a rule, unless it can be proved that the life of the patient depends upon it, and even then it would be safer to obtain the requisite authority for such a possible emergency, than to be without it on the forced assumption of an extra responsibility.

QUACK MEDICINES AND THE RELIGIOUS PRESS.

In a previous issue we made some criticisms upon the practice indulged in by religious journals, of advertising quack medicines. We believe that there can be but one view taken of this practice in question, which is that it encourages harmful impositions, and is grossly inconsistent with the principles of Christian morality professed by the papers in question.

There are some clergymen—and good ones too—who openly refuse to be trammelled by what they are pleased to call the prejudices of doctors. As long as this independence concerns only the adhesion to the various 'pathies that dangle about real medicine, we have nothing to say. The intelligence which can be coerced into a faith in infinitesimals is too small to affect anything but our sympathies, and we have found the clergy, as a whole, quite above the weaknesses of dogmatic medicine. But this quasi-endorsement of patented nostrums, which the organs of the clerical profession give, is quite another thing. In almost every case there are statements regarding the properties of the mixtures advertised, which are absolutely false. Moreover, this falsity is too glaring to allow of any excuses for its endorsement on the score of ignorance. Every intelligent and well-informed man, whether medical or clerical, knows that there is no specific for consumption, or for cancer, or for Bright's disease; furthermore, every man who assumes the responsibility of a widely circulated journal ought to act in accordance with such knowledge. The advertisement of a patent medicine, therefore, means in every case the proclamation of a positive falsehood. Some advertisements, to be sure, are ingeniously worded so as to give the impression that the drugs are specifics without actually saying so. But the lie is in them just the same. Yet these untrue statements are published in nearly every religious journal in the land, and are read and doubtless believed in by thousands.

In an examination of the recent numbers of leading religious weeklies we found that the false assertions (as defined above) regarding the efficacy of quack remedies were advertised in about the following proportionate number of times in each issue: *Zion's Herald*, 11; *Congregationalist*, 7; *Examiner and Chronicle*, 3; *Independent*, 3; *Observer*, 7; *Advocate*, 4; *Baptist Weekly*, 3; *Christian Union*, 2; *Appeal*, 2; *Christian at Work*, 6; *Evangelist*, 2. Total, 50.

It should be said in the above enumeration we only count one mis-statement to each nostrum, when, as a rule, there are half a dozen false statements or implications attached to every announcement.

With regard to the character of the mendacity thus so extensively perpetrated, we gladly admit that a certain proportion of the advertisements are, medically speaking, harmless. That is to say, the person who buys an appliance which is advertised in the *Evangelist* as "the only specific for malaria" will probably not be directly injured by wearing the appurtenance thus evangelically endorsed. On the other hand, it is a fact that the sure and permanent cures promised will not be made, and that any benefit obtained will be due to some ordinary drug, or to the imagination. On the whole, however, the effect of patent medicines upon the system, as well as upon society, is extremely bad. Some are dangerous, some are entirely inert, all are ridiculously high-priced, and all fail to fulfil the promises made for them. The purchaser wastes his money, prolongs his disease (perhaps fatally), and deludes himself with a silly confidence. What shall be said, then, of those censors of morality who advertise these injurious deceptions. They wrong their religion, they impose upon their patrons, and they injure themselves and the high cause they assume to advocate.

There is something almost repulsive in the incongruities which the union of religion and patent medicines brings out. Can the mind pass easily from "Helps to Prayer" to "Vinegar Bitters?" Can "Golden Thoughts" retain their ethical value by the side of cancer-cures and "the only genuine kidney-cure"? We had become much interested in a tender and pathetic poem of which the first verse was as follows :

> "In pastures green not always He
> Who knoweth best in kindness leadeth me,
> But ——"

and at this moment our eyes fell on the adjacent column : "9,000,000 bottles of this wonderful remedy sold in one year!" or words to that effect It is revolting to have a tribute to the compassion of our Lord thus cheek by jowl with Congo Balsams and South African Blood-Purifiers and Catarrh Cures!

There pervades through many of the religious journals the woodcut of an ancient lady who sits, *splendide mendax,* over an announcement of a wonderful compound that lifts up the fallen womb and cures all the diseases of women. "Stand fast by the faith" is a beautiful religio-journalistic motto which may apply to more columns than was intended.

How very weak the gospel truths appear when set off by the advertisement of a cancer-cure!

Perhaps we have said enough for the present. We shall have more to say by-and-by. Every week increases the richness of our therapeutical collection from religious literature. It will soon form a little pharmacopœia of itself—a pharmacopœia not hampered by the restraints of scientific method, but copious in language, magnificent in promises, and as full of ingenious falsehoods as if the Father of Lies himself were pharmacist, author, and rhetorician.

In conclusion we appeal to the clergy to use their influence in checking this abominable practice of advertising nostrums in religious journals, a practice which, we repeat, they cannot but characterize as inconsistent with high morality, injurious to religion, and pernicious in every way. We are glad to see that some religious journals, notably the *Evangelist* and the *Appeal,* indulge in the practice but mildly, and appear to have a dim consciousness that it is not noble or Christian to bolster up religion with patent medicine lies. As for the clergy and Christian people in general, we feel sure that it only needs a full and frank statement of the facts in order to excite their condemnation of the practice.

HOSPITAL SATURDAY AND SUNDAY.

To-day and to-morrow will be received by the committee, organized for the purpose, contributions to the Saturday and Sunday Hospital Fund for the present year. Although this plan of making collections for our charitable institutions is but a year old, it has received such hearty and substantial endorsements from every quarter that we can speak of it as being firmly established in public favor, and likely to become more and more popular as its real objects are made known. Already other cities are following the example of New York, and we hear that Philadelphia, Boston, Portland, New Orleans, and other cities, are contemplating the initiation of this laudable method of charity.

Extensive preparations have been made in the direction of systematizing the collection of funds, and there seems to be little doubt that the sum total for this year will be double that of last year. Not only will good opportunities be given to the ever-ready church contribution-box, but every other available means will be used to secure the end. The officers of the Stock, Produce, and other exchanges named last year acted as receivers for this fund; but this year, under committees of their own choosing, they become collectors also. The Chamber of Commerce, for instance, has appointed a committee who have sent out circulars to every member of the Chamber, calling the attention of the various business exchanges to the scheme and asking for individual contributions. The Cotton Exchange has also, through its committee, sent out a similar circular. Hospital boxes are placed at the various railroad stations, suburban and elevated, at hotels, ferries, drug-stores, and other public places, so that no one need be excused from giving from want of opportunity.

As an inducement to contributions by societies, by large manufacturing and business establishments, and in return for benefits from the theatres, it has been arranged that any such society, establishment, or theatre contributing the amount required by any one of the hospitals for the endowment of a bed in it for a year, or perpetually, may have such amount applied for such endowment in the hospital it may select, and thereby obtain the use of such bed for the limited or unlimited time for any of its members or employees.

It needs no words from us to urge the necessity of contributions to the fund. The hospitals forming the association have peculiar claims upon the charity of the public. These institutions care for the sick poor who are not paupers. Over ten thousand of these patients are treated gratuitously each year. For such medical men as are acquainted with hospital work it is not difficult to answer the question: What would become of these needy sufferers if the large hospitals in this city did not offer their aid by supplying free board, free lodging, and free medical service? But the people need only to be told the needs of these institutions to respond to the calls now made upon their charity.

The plan for distribution will be the same this year as last. Gifts designated by the giver, and collections taken in churches for any particular hospital, will be given to such hospital; while undesignated gifts will be distributed by a committee composed of his honor the Mayor of New York, the Postmaster of New York, the President of the Chamber of Commerce, the Rev. Thomas Armitage, D.D., and Messrs. Frederick Sturges, Henry E. Pellew, and Oliver H. Palmer, among the hospitals uniting in this association, according to the amount of charitable work done by each in the past year, with a discretion to the committee where the income of any hospital has exceeded its expenses, or where the designated gifts to it have been large.

It is not intended to interfere with the giving of designated gifts, but the association has wisely reached the conclusion that the greatest benefit to the work which it represents, and in the end to each hospital, will be accomplished by giving *undesignated* gifts.

This would give the committee the fullest possible scope for the exercise of discretion in the bestowal of pecuniary help, and would insure its equal and *pro rata* distribution among the hospitals.

THE AMERICAN PUBLIC HEALTH ASSOCIATION.

The recent annual session of this association at New Orleans seems to have been one of rather more than usual interest and success. The subjects of yellow fever and quarantine, which formed the backbone of previous meetings, were kept in comparative subordination on this occasion. There was, of course, the usual quota of papers showing the great utility of Boards of Health, and the necessity to a nation's prosperity of fully applying the latest and best methods of sanitation. But the association widened its field of discussion somewhat this year. The subject of contagious diseases among cattle was presented in a lengthy paper and received considerable attention.

The committee on the prevention of venereal diseases presented also an interesting and, in some respects, novel report. It recommended the enactment by state legislatures of a law making it a criminal offence for a person having a contagious disease, whether venereal or otherwise, to knowingly communicate this disease to another. This recommendation, which was endorsed by the association, was accompanied by a formal list of facts that ought to be generally known by the public regarding the means by which venereal diseases may be spread. This list we give in another column. It appears to us to represent the product of an imagination stimulated to a high intensity by syphiliphobia and philanthropy. But it is a document that may have its uses. Whether it should be made a popular health tract is a question requiring more consideration than was given it by the association.

A discussion upon the diagnosis of yellow fever occupied the last hours of the session and threatened at first to make them inharmonious. Matters were, however, amicably adjusted at last, and the society adjourned, leaving the impression that the members had done rather more and better work than ever before. This opinion was shared in by the public press which gave the association full reports and a hearty welcome.

Reviews and Notices of Books.

THE ART OF PROLONGING LIFE. By CHRISTOPHER WILLIAM HUFELAND. Edited by ERASMUS WILSON, M.D., from the last London edition. Philadelphia: Lindsay & Blakiston. 1880.

"The Art of Prolonging Life," by Dr. Hufeland, a philosophic physician and professor of medicine in the University of Jena, is, says the editor, a work enjoying deserved popularity in Germany. It was translated into English in 1797, but is scarcely known at all either in England or America. The editor was struck with the little real progress made in the science of living during the more than half a century since the original work was written. It appeared to him that it might be a useful thing to show how much remained to be done before our knowledge of the subject is complete.

The book is full of curious facts, historical and physiological. Its physiology and its hygiene are in the main pretty correct, yet the work should hardly be judged on its merits in these directions. The author takes Bichat's view of life: that it is a continual activity of destructive and creative powers within us. We call it now "metabolism," but the idea is the same. Life, however, with Hufeland, is the expression of a vital force, this vital force being a kind of *deus ex machina*, which co-ordinates nutritive and functional actions. This latter agent is what the modern physiologist would throw out entirely, since he finds that he cannot weigh it in his scales. As life cannot yet be explained, however, without assuming something beside the molecular *vis insita*, it does not appear that Professor Hufeland is so very far behind the age.

It is taken as the guiding principle of the book that length of life, other things being equal, depends upon the *intensiveness* of its activities. Life is compared to a flame—the hotter it burns the more quickly it is consumed. Many interesting facts in animal and vegetable life are given to illustrate this.

The book is a very entertaining one, and there is a great deal of sound sense in it on matters hygienic, moral, and physiological. Dr. Wilson has shown excellent judgment in putting it before the public and profession again.

THE USES OF TAR-WATER IN OBSTETRICAL AND GYNECOLOGICAL PRACTICE. By DR. J. E. ALLEN.

It is recommended by Dr. Allen that tar-water be substituted for carbolic acid in obstetrical and gynecological practice, and some excellent reasons are given for the change.

Seven Cases of Retroflexions of the Uterus; with Peritoneal Adhesions of the Fundus in the Hollow of the Sacrum. Treated by Forcible Separation of Adhesions. By Aug. F. Erich, M.D.

The title of this essay tells its nature. The author advocates the treatment of retroflexions indicated, followed by the use of a uterine stem. It is a new departure, and will be thought by many a dangerous one.

A Case of Puerperal Eclampsia, by Dr. J. E. Allen, presents the following points of interest:

1. The continuance of nausea and vomiting during the latter months of pregnancy. 2. The recurrence of the eclampsia on the third day after delivery. 3. The therapeutic value of hydrate of chloral. 4. The great value of bloodletting in puerperal eclampsia, and especially in apparently anæmic cases of the affection.

An Experimental Research on the Physiological Action of Drugs on the Secretion of Bile. By William Rutherford, M.D., F.R.S. Edinburgh: Adam and Charles Black. Oct., 1880, pp. 173.

This book details the results of a series of nearly one hundred carefully conducted experiments, extending over a long period of time, and undertaken to demonstrate what were and what were not cholagogues. The experiments were performed on dogs, which were the animals selected, because the anatomical arrangement and situation of its biliary apparatus were suitable for experiment, and because their digestion and susceptibility to the influence of drugs resemble that of man. The animals were fasting, and under the influence of curare to prevent interference with the discharge of bile by contraction of the abdominal muscles. Curare was shown to have no effect on the secretion of bile. The fluid in question was collected through a temporary biliary fistula, and after the experiment an autopsy was made in each instance to discover the effect on the intestinal glands of the drug experimented with.

Previous to these experiments our knowledge of the effect of drugs on the liver was meagre and uncertain. While it was known that certain drugs increased the quantity of bile in the fæces, it was not known whether they did so by increasing the secretion of bile or by stimulating the expulsion of bile already formed. The experiments throw no light on the latter question, but they bring the full glare of the sun to bear upon the former. The drug to be experimented with was injected into the duodenum, so that the effect produced could not be by reflex action from the stomach. The substances experimented with, as regards their power of stimulating the secretion of bile by the liver, may be classified as follows:

1. *Powerful:* Podophyllin, sodium benzoate, ammonium benzoate, benzoic acid (though less than its alkaline salts), sodium salicylate, euonymin, phytolaccin, iridin, sanguinarin, sodium phosphate, ipecac, ammonium phosphate, mercuric chloride (corrosive sublimate), and aloes, colocynth, and colchicum in large doses.

2. *Moderately powerful:* Leptandria, jalap, dilute nitro-hydrochloric acid, sodium sulphate, potassium sulphate, Calabar bean, baptisin, hydrastin, juglandin, rhubarb.

3. *Feeble:* Scammony, Rochelle salts.

4. *Very feeble:* Croton oil, senna, taraxacum, jaborandi, sodium chloride.

5. *Non-stimulants:* Magnesium sulphate, gamboge, castor-oil, ammonium chloride, sodium bicarbonate, potassium bicarbonate (unless in large doses), potassium iodide, atropia sulphate, menispermin, tannic acid, manganese sulphate, morphia, hyoscyamus, pure diluted alcohol, calomel.

6. *Depressants:* Lead acetate. Purgation by purely intestinal stimulants also diminished the secretion of bile.

Of the hepatic stimulants, classified as "powerful," the following also stimulated the intestinal glands: Podophyllin iridin, sodium phosphate, phytolaccin (slightly), and aloes, colocynth, and colchicum in large doses. Those experimented with which did not stimulate the liver, but stimulated the intestinal glands, were: Magnesium sulphate, gamboge, castor-oil, ammonium chloride, menispermin (slightly).

Among the many changes which the generally received therapeutics will have to undergo, as the result of this work, none are more noticeable than those relating to the position of calomel and corrosive sublimate. The action of ipecac is defined; euonymin, phytolaccin, iridin, sanguinarin, sodium phosphate, etc., are brought to the notice of the profession as powerful hepatic stimulants; croton oil is removed from the list; while magnesium sulphate is shown to differ materially in its action from potassium sulphate. In addition to the inestimable value which it has from a therapeutical point of view, this work, unless we are much mistaken, will necessitate a change in the pathology of a number of diseases, notably dysentery, rheumatism, gout, syphilis, and perhaps diphtheria. It is a long time since so valuable a contribution was made to practical medicine.

Report of Ten Cases of Gastric Ulcer, Etc. By A. Van Derveer, M.D. Albany. 1880.

The author of this pamphlet has made an interesting contribution to the clinical history of gastric ulcer. The cases illustrate, more than anything else, the occasional difficulty of diagnosing the disease, and the comparative inefficacy of medication. In the case of a Miss D., for instance, the patient was told that she had cancer by five prominent physicians in Europe and this country; by five others she was assured that she had gastric ulcer. She now seems to be getting well.

Walsh's Physicians' Handy Ledger. Ralph Walsh, M.D. Washington, D. C.

This is a ledger which well deserves its name. It is so arranged that each page is devoted to the daily account of one patient for a year, with columns for debit, credit, and date of payment. At the bottom of the page is a space for special charges for obstetrical, surgical, or miscellaneous services other than daily visits. Not only is the account of each month kept by itself at the end of its respective horizontal line, but each day has its space. It is the best book of its kind that we have seen.

China, Imperial Maritime Customs. Medical Reports for the half-year ending September 30, 1879. Shanghai. 1879.

This report is one of a series which has been regularly issued by the Inspector-General of Customs for some years. It contains a monograph on Cholera Epidemics in Japan; notes on Filaria Sanguinis Hominis and Filaria Disease in Amoy; Lithotomy Statistics from the Canton Native Hospital, and reports on the Health of Canton, Shanghai, and several other ports of China.

The article by Dr. D. B. Simmons, on Cholera

Epidemics in Japan, we notice in the next column. The article by Dr. Patrick Manson, of Amoy, on Filaria Sanguinis Hominis is well worthy the attention of pathologists. Dr. Manson is an ardent believer in the parasitic theory of elephantiasis, and he brings many new facts to the support of his convictions. Some contributions are made also to the life history of the filaria. The article is illustrated by numerous photographs of cases. His conclusions are stated at too great length to be given here. In general, he thinks that the ova or embryo of the filaria obstruct the lymph circulation through the glands. If this obstruction be incomplete, lymph scrotum, or chyluria, or varicose groin glands result; if it be complete, there is often elephantiasis.

The health reports of the different cities are well made up, and doubtless have much local value.

Dr. Fleming Carrow gives a table of operations for stone performed at the Native Hospital, Canton. There were 140 operations, mostly by the lateral method, and only eight deaths. The statement of this remarkably low mortality rate is made without comment or boasting, and is an evidence as much of great modesty as of unusual skill.

Supplement to the First Annual Report of the State Board of Health, Lunacy, and Charity, containing the Report and Papers on Public Health. 1879.

The present report, the first that has been made by the combined board, shows no falling off in the excellency of the matter that has been annually furnished by the health authorities of Massachusetts. The list of articles is quite a long one. A paper by the secretary on "The Pollution of Streams" gives the results of a careful examination into the effect of mill-refuse upon the purity of the rivers which receive the waste products of manufactories. No very serious pollution seems to have been discovered.

The paper of the greatest scientific merit is that by F. S. Billings, M.V., on "Trichinæ in Relation to the Public Health." Dr. Billings gives the natural history of the trichinæ, illustrating his subject amply, and concludes with advising certain measures of prevention to be adopted by the State. These measures include the examination of slaughtered pigs by competently educated veterinary inspectors.

A paper by Ellen H. Richards, on "The Adulterations of Some Staple Groceries," has been already commented on in this and other journals. We have also noticed some of the facts given by Mr. E. W. Bowditch in his paper on "The Drainage of Summer Hotels and Country Boarding-Houses." The article is profusely illustrated with diagrams and cuts, and it is the best contribution that has yet been made to a subject now deservedly arousing much attention.

There are half a dozen papers upon the vegetable or other impurities in drinking-water. These have a botanical quite as much as a sanitary value.

Several reports upon typhoid fever conclude the volume.

Transactions of the Medical Association of Georgia. Thirty-first Annual Session, Augusta, April 21, 22, 23, 1880.

The oration of the President, Dr. W. S. Kendrick, is eloquent, poetical, and eminently Southern in its character. It is an appeal to his auditors to follow the guidance of their nobler feelings, thus striving to elevate themselves and their profession.

Dr. Robert Battey furnishes an article on "Scrofulous Disease of Joints Complicating Phthisis." He contends that in many cases it is advisable to remove such joints by amputation, and he gives cases illustrating the benefits of the practice.

In a report of "Forty-two Cases of Uncomplicated Stricture of the Urethra," by Dr. Wm. S. Armstrong, more evidence is given in favor of dilatation as against urethrotomy in the treatment of strictures.

Most of the other papers are reports of special cases. They include cases of "Polypus in the Rectum," "Congenital Phimosis Causing Nervous Phenomena," a case of "Double Ovariotomy, with Death from Tetanus," "Spermatorrhœa," "Reports on Gynecology," etc. The volume contains rather more than the usual number of valuable papers.

Cholera Epidemics in Japan, with a Monograph on the Influence of the Habits and Customs of Races on the Prevalence of Cholera, by D. B. Simmons, M.D., Chairman of the Yokohama Foreign Board of Health, etc. Shanghai. 1879.

In this report and monograph Dr. Simmons has given a very full history of the cholera epidemics of Japan as well as of China. With this are many interesting facts regarding the disease as it appeared lately in the former country, and regarding the effect of particular modes of life upon its course.

Dr. Simmons states that in the epidemic of 1877 in Japan there were 12,378 cases in a population of 32,000,000. Of these cases 52.58 per cent. died. In 1878 there were 975 cases, with 54.56 per cent. of deaths, and in 1879, 164,274 cases, with a mortality of 59.30 per cent. The disease was brought into the country by foreign vessels, and, reaching the seaports, it rapidly developed and spread despite active sanitary measures.

The mode of contagion was chiefly by the poisoning of the drinking-water with excreta or vomit. Contagion was sometimes carried also by moist, heavy vapor from infected sewers or cellars, or by inhalation during the process of washing clothing soiled by choleraic discharges; also by dust rising from the dried evacuations of cholera patients. Dr. Simmons admits no other means, but contends that these are fully established. The treatment employed did not seem to have much effect. The Chinese doctors had about as good success as the regularly educated medical men. Dr. Simmons had used pilocarpin for its action on the kidney, and speaks highly of its efficacy in many cases. Preventive measures, such as secured good drinking-water, isolation, proper food, and proper disposal of excreta, were very efficient in limiting the disease. Disinfectants are not rated very highly. The author gives some curious facts regarding the mode of obtaining drinking-water and of disposing of excreta among the inhabitants of India, China, and Japan. The natives of India will not use latrines. More than 150,000,000 of people, therefore, in that country, deposit their evacuations on the ground. Their drinking-water is obtained from wells, tanks, and streams, each of which is liable to infection. These habits are the chief causes, when taken in connection with the religious pilgrimages, of the existence and rapid spread of the cholera.

In China, on the other hand, the excreta are deposited in boxes; these are cleaned daily, and the contents taken by the scavenger to be used as manure. There is, in consequence, very little danger of contamination of drinking-water; and to this custom of caring for the excreta, and of using better drinking-water, Dr. Simmons ascribes the comparative immunity of China from great cholera epidemics, in spite of its proximity to India.

The Japanese use as latrines tanks sunk in the ground. These very often leak, and thereby poison the soil and the drinking-water. The Japanese are less careful than the Chinese, though vastly more than the Indians.

Dr. Simmons' report contains numerous statistical tables, maps, together with much historical matter, all compiled evidently with great care and labor. He is to be complimented on having furnished a valuable contribution to sanitary science and epidemiology.

Transactions of the Medical Association of the State of Missouri. Twenty-third Annual Session, Carthage, May 18, 19, and 20, 1880.

This volume, though small, contains several articles which have been pretty extensively noticed during the past summer. Among these are Dr. Engelmann's article on "The Dangers that Accompany Uterine Manipulations." It represents much research, and is an important contribution to gynecology. Dr. Todd's paper on the "Dry Method of Treating Discharges from the Ear" deserves attention also. The address of the President, Dr. Maughs, on "Medical Ultraisms," contains some very sharp hits on certain medical fashions and the vagaries of specialists. The Report on Medical Education may have been written with the best intentions, but it is an extremely weak document, viewed from any point except that of an advertisement of the seven medical schools of Missouri.

Transactions of the Iowa State Medical Society, Vol. IV., 1879–80.

This volume has some peculiar features in it which lend considerable value to what, as a whole, is rather commonplace. There are, for example, a number of excellent lithographs of deceased members of the Society, and the necrological department, in consequence, makes quite a fine appearance. The book contains also a complete list of the members of the Society, the constitution and by-laws, and the medical laws of the state, including the recent one for regulating the practice of pharmacy. The proceedings of the Society at its meeting in June, 1879, and in January, 1880, are included in this single volume. There are eighteen papers, and, as representing the work of the Society for two years, they do not make a very rich display.

A Contribution to the Study of Inflammation, as Illustrated by Induced Keratitis. By W. T. Councilman, M.D. Prize essay of the Baltimore Academy of Medicine.

We can strongly commend this essay, both as showing careful original work and a clear and concise method of presenting it. Dr. Councilman's investigations lead him to disagree with Stricker's theory, that the corneal corpuscles proliferate into "wander-cells." He believes that these latter cells come from the blood-vessels, and that the corneal corpuscles in proliferating only reproduce cells of their own kind, never pus-cells.

Dr. Councilman describes what he sees with powers of a thousand diameters. This, together with some of his diagrams, lead us to think that his conclusions cannot be considered final, though he makes out a strong case.

Den Miasmatiskt-Kontagiösa lungsotens och den kroniska lunginflammationens verkliga orsaker och medlen att förebygga dem. Af Med. Dr. Fredrik Eklund, Forste Bataljons Lakare vid Kongl. Flottans Station i Stockholm. Stockholm, 1880. 12mo, 16 pp.

The True Cause of Miasmatic Contagious Phthisis and Chronic Pneumonia, and Means for their Prevention.

The author, stationed at Stockholm, has at his disposal an immense amount of material obtained from the royal navy. He regards phthisis sputa, to a certain extent, as the true expression of the morbid phenomena occurring in the lungs. He finds that the former contains three specific and characteristic cell-forms, which are numerous in exact proportion to the gravity of the case. These are: 1st, small, round, lymphoid cells, usually completely filled with phthisis bacteria; 2d, round cells with from three to five nuclei; these cells are about the size of pus-cells or white blood-cells, and either filled completely, like those under No. 1, with phthisis micrococci, or containing only a few (2–3–5) of the latter; 3d, elliptic and oval cells, narrower but longer than those described under No. 2, but containing the same number of bacteria as the latter. These bacteria are called "Micrococcus Phthisis Dryotemenos." The author instituted many experiments and examinations to assure himself that the above-described cells did not occur in the secretion of the salivary or other glands, or in the mucous membranes of healthy persons or of those otherwise affected. All the observations were made with Vérick's objective No. 8, eye-piece No. 3, with the tube drawn out full length.

The author procured specimens of earth, mud, and water from districts where phthisis prevailed, as well as decomposing vegetable and animal matters from low marshy places, and constantly found in them micrococci which were in all respects identical with phthisis bacteria. He therefore considers tubercular phthisis a miasmatic disease as well as a contagious one, and that the above described cells, floating in the air, constitute the contagious principle.

The preventive measures consist in drainage, ventilation, cleanliness, dryness, etc.

Correspondence.

HYSTERO-EPILEPSY OR HYSTERIA MAJOR.

To the Editor of The Medical Record.

Sir—After reading in your journal the interesting letters of Dr. Morton, from Paris, on the above subject, and by way of answer to the doctor's query, "Where are our hystero-epileptics in America?" I will report the following case, which will indicate where, at least, one of them may be found:

Ella C——, aged twenty years, single, domestic, was admitted September 8, 1880, supposed to be suffering from acute melancholia. Very little of her history could be obtained, and the cause of her insanity, as well as its duration, was unknown.

There was much cerebral excitement accompanying her delusions, which were of an unusual character. To her nothing was real. There were no people, no houses, no world. If asked about her appetite—there was no food. If how she slept—there was no sleep. Her expression and tone of voice, as well as delusions, indicated utter despair. Her general health was not much impaired—tongue slightly coated, appetite capricious, bowels regular, heart and lungs normal; urine, specific gravity 1020, non-albuminous and precipitating phosphates by heat. Began menstruating day after admission. She was soon placed on tinct. cinchon. co., and bromide potass., gr. xx. t. d., with manifest improvement, after a week, in both mental and bodily symptoms.

Nothing peculiar occurred in her case until October 7th, when I was hastily summoned and found her lying on the floor, with head strongly retracted, neck rigid and swollen, face slightly congested, eyelids tightly closed, body contorted, and extremities executing the most varied and violent movements. At the same time she was directing the nurses to do this and that for her, and frantically calling for water, which, when given, was swallowed in small quantities and with the greatest difficulty, owing to the trismic condition present.

It required but a moment to see that at least the so-called hysterical element was prominent, and with the thought, I dashed some cold water in her face. She gasped, and with it disappeared all active movements, but the relief was only momentary. As soon as she was placed on the bed the contortions were repeated. There was a brief period of tonic spasm, or "tetanic rigidity," when the head was thrown back, and the body became opisthotonos. Noticeable features at this moment were the swelling and widening of the neck, and the bulging, if I may so express it, of the abdominal walls. Then followed the clonic stage, when her floundering became most extravagant, requiring four attendants to keep her on the bed. Her eyelids were again firmly closed, and she cried that her eyes were "bursting." The lips were soon covered with frothy mucus.

I succeeded, with difficulty, in giving a hypodermic injection of one-fourth grain morphia, but it was of no avail. Cold water, though frequently thrown in her face, had lost its effect.

The paroxysms were rapidly repeated, each lasting from three to four minutes, while the interval of repose was not more than half a minute. There were brief periods of entire loss of consciousness.

The temperature and pulse, though not accurately taken, seemed but little affected.

It now occurred to me to try the procedure of Charcot which I had formerly seen described in his clinical lectures. Therefore, finding that there was great sensitiveness in the left ovarian region, I made firm and deep pressure during a seizure, with my thumb and first finger at a point about three inches within the left anterior superior spinous process. The effect was instantaneous. Complete relaxation followed, though consciousness was not immediately restored. Removing the thumb and waiting but a moment, convulsive movements again succeeded, which were again arrested by compression.

This experiment was made again and again, until there was left no doubt that the seizures were completely controlled by the pressure.

It was interesting to observe the facial expression during compression. At first it appeared to give her intense pain, but the deeper the thumb passed the greater was the relief, until the face wore a complacent calm. Steady pressure was maintained about twenty minutes, a hypodermic injection of three-eighths grain morphia given, and a belladonna plaster applied over left ovary.

She rested for some hours, but had a light attack the same evening.

About a week subsequent to the above, when she seemed nearly as well as at any time since admission, an attempt was made to artificially induce a seizure, which would have been entirely successful had it been carried far enough. While she lay upon the bed I made gentle pressure in the same iliac region, when immediately ensued all the symptoms which announce an attack—abdominal spasm and distention, frequent attempts at swallowing, rolling of the eyes, facial grimaces, and momentary loss of consciousness. But removing the thumb at this instant, before the convulsive stage was inaugurated, she quickly recovered, and looked about confused and bewildered. Had the fit become fully established I would merely have increased the pressure instead of suspending it.

Since the above date (October 7th) she has had four or five light attacks, differing materially from the severe and prolonged series above mentioned. Fifty grains bromide of potassium have been given her two hours after breakfast, and thirty grains of the same bromide with fifteen of chloral hydrate at bedtime. Cantharided collodion has been painted a few times over the left ovarian region.

Her mental agitation and apprehension are much less than formerly, and her delusions, while they have not entirely disappeared, are rarely repeated.

Paralyses or contractures have not been observed, though left hemianæsthesia is marked. Catamenia have been regular. There are no evidences of specific taint.

SAMUEL AYRES, M.D.,
Assist. Physician Western Penn. Hospital for Insane.

DIXMONT, PA., November 27, 1880.

New Instruments.

A CELLULOID CANULA FOR INTRA-UTERINE INJECTIONS.

By J. D. TRASK, Jr., M.D.,
ASTORIA, NEW YORK.

THE necessity of thoroughly washing out the uterus in some forms of disease met with in the lying-in is admitted by those having the most experience.

The canula used for this operation should be so constructed as to render the introduction of air into the uterine cavity during the operation *impossible*.

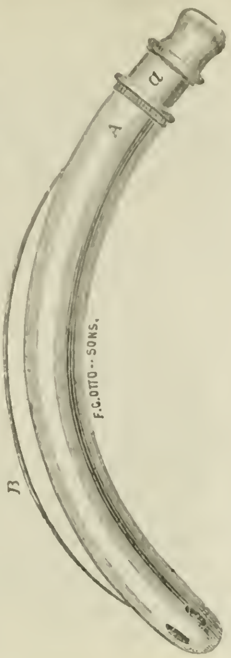
There should be ample provision made for the reflow of the fluid in those instances where the uterus is liable to contract upon the instrument, as in cases of post-partum hemorrhage where astringent injections are used.

The material of which it is made should be non-absorbent, and its shape should be such as to render its introduction safe and easy.

Not being able to find an instrument that answered these requirements, I had Messrs. F. G. Otto & Sons make for me the one here represented.

It consists of two canulas, *A*, *a*, the inner one, *a*, fitting snugly though moving freely within *A*. The distal end of *A* is rounded and perforated, while the inner tube is made to fit down upon its "valve-seat" in the extremity of *A*.

B is a guard sprung from one extremity to the other, so as to prevent the uterus grasping the instrument, and thereby cutting off the escape of the injected fluid.



The instrument is placed in a basin of water and the inner tube withdrawn a short distance, so that any air it may contain shall be expelled. The tube of the (previously filled) fountain syringe is slipped over the shoulder of the inner tube *a*, and *a* is firmly pushed down upon *A* valve-seat. This part of the operation must be done under water. We now have the instrument "loaded," ready for introduction, and it does not contain any air. When the canula is introduced within the uterus, the inner tube is withdrawn a short distance and the injection flows out through *A*.

By the use of this instrument the danger from the introduction of air is avoided. There is ample provision made for reflow. The material of which it is made is a very great point in its favor; celluloid being as light as meerschaum, as strong as brass, and susceptible of very high polish. It is not acted upon by any agent liable to be used as an injection. It should not, however, be put in boiling water, as that renders it pliable.

The cut does not give a correct impression of its proportions. The tube *A* is five-eighths of an inch in diameter and twelve inches in length.

LOCAL MEDICATION OF THE DEEP URETHRA.

By CHARLES L. MITCHELL, M.D.,

PHILADELPHIA, PA.

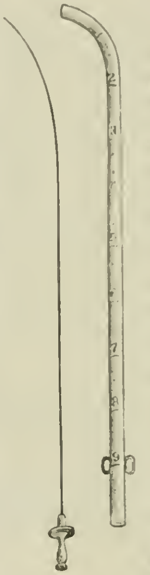
It is a fact recognized in all modern works on urethral diseases, that in the majority of cases of long-standing gonorrhœa or gleet the inflammation is located in the deeper portions of the urethra.

Bumstead and Taylor, in their work on "Venereal Diseases," p. 39, speak as follows: "We have reason to believe that in the course of an attack of gonorrhœa the disease gradually extends from the outer to the deeper portions of the canal, *and it is in this latter situation that it is prone to lurk for an indefinite period.*"

Otis ("Stricture of the Male Urethra," p. 14) says: "In cases of long-standing gleet the discharge is often found to proceed chiefly, if not wholly, from the deeper parts of the urethra, the bulbous and even the prostatic portion." Again, in prostatorrhœa, spermatorrhœa, impotence, etc., a similar condition is noticed. According to Dr. S. W. Gross, "hyperæsthesia in the curve of the urethra, which embraces the prostatic and membranous regions, and the portion one inch anterior to the triangular ligament, is always found."

Exploration of these regions with the bougie-à-boule will discover great tenderness, and the head of the instrument will, on withdrawal, very often be found coated with muco-purulent matter.

In the treatment of all these cases it has been deemed of great importance to bring the diseased localities under the direct effect of various remedies, those of an astringent, stimulating, or sedative character being generally preferred. The agent most employed for making these applications is the ordinary urethral syringe, but, when used, it generally fails in reaching the deeper portions of the channel and producing a beneficial result. I can do no better than quote again from a very high authority on this point (Bumstead and Taylor, p. 93). "In the ordinary method of injecting the male urethra it is difficult to make the fluid pass through the whole extent of the canal into the bladder. After a certain portion (about half an ounce) of the contents of the syringe has been injected, the remainder escapes above the piston, or, however tightly the glans may be compressed around the point of the instrument, flows from the meatus. The obstruction to the entrance of the fluid is due to the contraction of muscular fibres (the compressor urethræ muscle) which surround the membranous portion and serve as a sphincter to the urinary canal; *and this is the posterior limit of the application of the fluid to the urethral walls by the more common method of injecting.*" In order to reach these deeper and more inaccessible parts it is therefore necessary to make use of either the deep urethral syringe (of which there are several varieties) or the cupped ointment sound. While acknowledging the value of these instruments, the writer wishes to call attention to a new instrument and method for making applications to the deep urethra, particularly the prostatic region, and which will far surpass in favorable results the advantages heretofore obtained by any other method of local medication.



The instrument (see cut) consists of a canula ten inches long, of the calibre of a Number 20 sound (Fr. scale), bent to a Thompson's curve and graduated to a scale of inches, commencing at the vesical extremity. Through this canula plays an elastic steel stilette, tipped at one end with a probe-point, and forming, when fitted into the tube, a rounded and smooth extremity. With this instrument is used a series of small, soluble bougies or suppositories about an inch and a half long and of suitable diameter to slip easily through the tube.

These bougies are best made from gelatin and glycerine. This compound offers the advantages of ready solubility and great flexibility, thus allowing the bougie to pass through the curve of the canula with ease. Cacao butter can also be used as a vehicle should the nature of the medicament be such as to forbid the employment of gelatin. It cannot be used alone, however, as it would make a stiff, brittle suppository, and one which could not be forced through a curved tube. It must accordingly be kneaded in a mortar with a suitable quantity of powdered gum tragacanth and glycerite of starch until a flexible mass is obtained. This is then properly medicated, rolled out on a pill tile or slab into thin pipes, and cut to a suitable length. This compound is only adapted for extemporaneous prescriptions, as it will not remain soluble or flexible and must be used while fresh; on the other hand, the gelatine mixture will keep in good condition for a long while.

The medicating ingredients used in these bougies are sulphate, acetate and chloride zinc, acetate lead, tannic acid, iodoform, sulphate morphia, extracts of belladonna, opium, hyoscyamus, gelsemium, hydrastis, and ergot, carbolic acid, liq. iodinii comp., etc., and can be varied in strength to meet the indications of the case.

The method of applying the bougies is as follows: The particular spot desired to be treated having been ascertained by the bougie-à-boule, or other convenient means, and its distance measured from the meatus, the bougie-carrier is passed into the urethra until its extremity reaches the desired place, this being ascertained by the graduation on the instrument. The tube is then steadied, the stilette withdrawn, a soluble bougie, well oiled, placed in the end of the canula and then forced down with the stilette until it is ejected from the instrument into the urethra. The whole operation need not take a minute. The patient should be instructed to pass his water a short time before the introduction of the instrument, so as to allow the bougie as long a time as possible to act before being washed away by the urine. No other precaution need be observed, and he may go about his business as usual. These applications may be made daily, or every alternate day, as thought best.

This method claims the great advantages of locating the remedy at one particular place, and *direct* and *prolonged* action, the bougie gradually dissolving, and thus exercising a continuous effect for a long period. The use of these bougies has met with great success, and I confidently believe that by their employment the surgeon will be greatly assisted in the treatment of many very difficult and annoying cases. While not in any wise advocating the disuse of other long-tried and well-known methods of procedure, I hope this plan of treatment will be recognized as a far superior agent, and an important and useful factor in bringing about a successful result.

839 Race Street.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from December 12, 1880, *to December* 18, 1880.

Benham, R. B., First Lieut. and Asst. Surgeon. Relieved from temporary duty at Fort Snelling, Minn., and assigned to duty at Fort A. Lincoln, D. T. S. O. 165, Department of Dakota, December 8, 1880.

Medical Items and News.

Contagious Diseases — Weekly Statement. — Comparative statement of cases of contagious diseases reported to the Sanitary Bureau, Health Department, for the two weeks ending December 18, 1880.

Student Riot in Philadelphia.—It may be remembered that last spring, when the Medical College of the University of Pennsylvania held its commencement, the ceremonies were greatly disturbed and interrupted by the demonstrations of the academic students of the same university. Last week, on Thursday, the medical students had their revenge. The sophomore class of the university prepared, on the evening of that day, to go through the mock ceremonial of "burying the syllabus." The cremation exercises occurred on the campus, and the students arrived on the spot about 9.30 o'clock, accompanied by an escort of fifty policemen, as it had been hinted during the day that the medical students would break up the exercises. When the sophomores, to the number of fifty, arrived on the ground, they found a gathering of several hundred medical students and others. As the ceremonies went on the audience did their best, by hooting and various derisive noises, to make everything ridiculous. Some attempts were made also to break through the ropes and stop the exercises altogether. This finally ended in a general *mêlée* between medical and other students and policemen. Pistols were fired, stones thrown, and clubs freely used. A good many were injured, though none seriously so, unless it was a young dental student who was shot in the thigh. Ten medical students were arrested and three policemen sent to the hospital. The affair caused great excitement in West Philadelphia.

It is claimed that the trouble was due to the fact that the academic students had notified the police of a possible row, and that these policemen initiated the quarrel by their unnecessary use of clubs and pistols.

The action on the part of the medical students cannot be justified, but it must be admitted that the provocation given by the occurrence of last spring was very great.

The University Medical College is one of the best and highest in standard in the country. It deserves some respect, therefore, from the academic department, which, as a classical college, rates among the lowest.

A Cargo of Small-Pox.—One of the Anchor Line steamers arrived at this port recently with 750 steerage passengers, mostly Italian lazzaroni, on board. At quarantine the health officer found that two of these passengers had small-pox, and two others had had it. There had been no attempt at isolation or vaccination, consequently the whole crew had been more or less exposed. The sick cases were at once removed to the Small-pox Hospital on Blackwell's Island. The rest of the passengers and crew were at once vaccinated, and then, as fast as accommodations could be prepared, were transferred to Hoffman's Island. There they were obliged to surprise their systems with a bath, and their clothes and persons were disinfected. They were kept in quarantine on this island until the vaccinia appeared, and all danger of small-pox developing appeared past.

A Royal Medal of the Royal Society has been conferred upon Mr. Lister in recognition of his important services in physiology and surgery.

Scarlet Fever is very prevalent throughout England.

The Death of Dr. Alfred Hudson, of Dublin, at the age of seventy-two, is announced. Dr. Hudson made many valuable contributions to medical literature during his lifetime, and had, at his death, a reputation scarcely second to that of his late townsmen, Dr. Stokes and Sir Dominic Corrigan. Says the *British Medical Journal*, it was he who first gave a rational explanation of the phenomenon of tympanitic resonance over a solidified lung. To him also was probably due the discovery of the value of vocal fremitus as a diagnostic sign, and by his teaching he did much to elucidate the facts which make the now generally recognized distinctions between typhus and typhoid fever.

Guy's Hospital has 180 beds closed, and there is a deficit of $50,000 in its treasury. Dr. Hilton Fagge and Mr. Davies-Colley have been elected to the vacancies caused by the resignations of Dr. Habershon and Mr. Foster.

Nomenclature of Diseases of the Royal College of Physicians.—A committee of thirty, including some of the most prominent medical men of London and vicinity, has been appointed to superintend the decennial revision of the nomenclature of diseases. It may be remembered that the National Board of Health has appointed a committee to confer with the one just appointed by the Royal College.

The American Public Health Association and the Prevention of Venereal Diseases.—A committee was appointed by the American Public Health Association, a year ago, to investigate and report upon the subject of venereal diseases and the means of preventing their spread. This committee made its report through Dr. Albert Gihon, U.S.A., at the recent meeting of the association in New Orleans. The committee asserted their belief in the efficacy of regulating prostitution, but they would not recommend the measure at present. They said that as a safeguard and warning everybody should know the following facts—that venereal diseases are communicable :

1. By the blankets, etc., of a sleeping-car, and the sheets, towels, and napkins of hotels and restaurants.
2. By the dresses, costumes, etc., rented for fancy balls.
3. By the chipped edge of the coffee-cup ; and by the half cleaned knives, forks, and spoons of restaurants and hotels.
4. By the drinking-vessels in a railway car or station.
5. By barbers' utensils—brush and comb ; by hatters' measure or by a borrowed or sample hat.
6. By surgeons' or dentists' instruments ; by the vaccinator or lancet.
7. By toys sold to children by venders who have been handling them with poisoned lips or fingers.
8. By the broom or dust-brush handled by the housemaid, or by the spoon fouled by the mouth of the cook.
9. By playing-cards and visiting-cards which have been used by syphilitics ; by car-tickets and paper money which circulates in a city where there are many syphilitics.
10. By the pipe, cane, or glove loaned to a friend.
11. By the grasp of a friend's hand or the kiss of an accepted lover.

In view of this alarming state of things the committee reported the following resolution, which after some debate was adopted by the Association :

Resolved, That the American Public Health Association earnestly recommend the municipal and state boards of health to urge upon the legislative bodies of this country the enactment of a law constituting it a criminal offence to knowingly communicate, by any direct or indirect means, a contagious disease, such as small-pox, scarlet fever, or venereal disease ; and giving to said boards of health and to the state and municipal health officers under their control the same power in the prevention, detention, and suppression and gratuitous treatment of venereal affections which they now possess in the case of small-pox and other contagious diseases.

Hospital for Incurables.—Henry C. Gibson, Esq., a well-known citizen of Philadelphia, has made a donation of $50,000 to the Incurable Ward of the Hospital of the University of Pennsylvania. A ball on a large scale will soon be given by the leaders of Philadelphia society for the purpose of raising additional funds for this laudable object.

Buchanan's Penalty.—The bogus diploma vender, John Buchanan, has been sentenced to pay a fine of $500 and to undergo imprisonment for ten months in the penitentiary, for endeavoring to defraud the United States Government of his bail by pretending to have committed suicide by drowning. This penalty has nothing to do with other crimes for which Buchanan was arrested.

American Social Science Association—Health Department.—At a meeting of the Council of the American Social Science Association, held in New York on the 10th inst., the Health Department was reorganized with the following list of members: Walter Channing, M.D., Boston, chairman ; E. W. Cushing, M.D., Boston, secretary ; E. M. Hunt, M.D., Metuchin, N. J. ; Horatio Bridge, M.D., Chicago, Ill. ; Prof. W. H. Brewer, New Haven, Conn. ; J. C. Hamilton, M.D., Mobile, Ala. ; Geo. E. Waring, Jr., Newport, R. I. ; Emily Pope, M.D., Boston ; J. S. Billings, M.D., Washington, D. C. ; S. B. St. John, M.D., Hartford, Conn. ; David Hunt, M.D., Boston ; Charles B. White, M D., New Orleans, La. ; D. F. Lincoln, M.D., Geneva, N. Y. ; Mary Putnam-Jacobi, M.D., New York ; Henry B. Baker, Lansing, Mich. ; John Rausch, M.D., Springfield, Ill. ; Elliot C. Clarke, Boston ; E. C. Seguin, M.D., New York ; Dr. Plummer, San Francisco, Cal. ; A. N. Blodgett, M.D., Boston ; C. F. Wingate, New York ; Elisha Harris, M.D., New York.

Dr. Antonio G. de Tejada died after a short illness, at his late residence, No. 54 West Thirty-fifth Street, in this city, December 12th. He was born in Carthagena, United States of Colombia, in 1845. His father, Rafael G. de Tejada, was a merchant in the Spanish trade in that city, who came to this city in 1855 and began business in Front Street. He died two years later. Dr. de Tejada was educated in St. John's College, Fordham, and subsequently followed a course of study in Bellevue Hospital Medical College, from which he was graduated in 1872. He was unmarried, and lived with a widowed mother and four sisters.

Dr. Pepper Nominated for Provost of the University of Pennsylvania.—The trustees of the University of Pennsylvania have placed Dr. William Pepper, Professor of Clinical Medicine, in nomination for the provostship of the University. The nomination lies over for a month, but there is no nominee in opposition to Dr. Pepper.

Death of Dr. W. T. C. Glazier.—We regret to announce the death, on December 12th, of Assistant Surgeon W. T. C. Glazier, U S.M.H.S. Dr. Glazier died at his post in Key West, Fla., of yellow fever. He was born in 1839, at Erie, Pa., and graduated in medicine at the College of Medicine and Surgery, Cincinnati, in 1871, and at the University Medical College, New York, in 1876. He was acting assistant surgeon U.S.A. from August, 1872, to November, 1875, being post surgeon at Fort Ellis part of that time. He was appointed on the Marine Hospital Service in 1878. Dr. Glazier lived in this city for several years and was well known to the profession here, where he was very much esteemed. During his stay in New York he assisted Dr. Stephen Smith in the preparation of his "Manual of Operative Surgery," collecting material and contributing many of the illustrations. Since leaving New York he had been engaged in working up the subject of "Trichinosis," and his completed monograph has just been given to Congress for publication. It is said to be the most exhaustive article upon the subject that has yet appeared in this country, and contains the results of much original work. Dr. Glazier was a person of much energy of character, industry, and executive capacity. When a boy he had very slight educational advantages, but his industry and ambition atoned for this, and at his death he was the superior of most professional men in general and medical attainments. In his personal character Dr. Glazier was above reproach. He was a genial companion, a true friend, and upright man. He died of the pestilence while in discharge of his duty. His death is an untimely loss, which will be widely and sincerely lamented.

Injection for Gonorrhœa.—Dr. W. Thornton Parker, of Plymouth, Mass., writes to us extolling the following as an injection for gonorrhœa: ℞. Zinc. sulphocarbolat., ʒ j.; aqua, ℥ vi.; mucil. acacia, ℥ j.; ext. opii. aq., ℈ j. Use night and morning.

American Students Abroad.—Thirty-eight out of ninety-five foreign students at the University of Vienna, during the past summer, were Americans.

Small-pox has been increasing of late in London.

Typhoid Fever has been alarming the inhabitants of Montreal. There have been over 100 cases there at a time.

Guy's Hospital.—Dr. Habershon and Mr. Cooper Foster have at last sent in their resignations as members of the visiting staff of Guy's Hospital. Their letters of resignation are dignified in tone and are accompanied with a protest against the nursing system as it now exists at the hospital. The resignations were given so late that the sympathy with these gentlemen will not be as full as it might have been.

Auscultatory Percussion.—This subject has been revived by Dr. T. A. McBride, in the *Archives of Medicine*. He has devised an instrument made of hard rubber, and in shape something like the ordinary common stethoscope without the mouthpiece. With this placed in the ears, percussion marks out the boundaries of the different viscera very accurately so far as has been tried. Its chief superiority over Camman and Clark's old instrument is that it can be used by one person alone.

A Case of Congenital Absence of the Spleen is related by Drs. Kods and Wachsmuth. The man had lived to the age of forty-nine years in good health. The other abdominal viscera were normal. The patient died of typhoid fever.

Climate-Cure of Phthisis.—Several interesting cases have been reported by Dr. Prosser James, which show very strikingly that there is no single best climate for phthisis cases. Indeed, they rather indicate that the chief factor in climate therapeutics is the change. The histories of five cases are related: in each case the patient went to another climate than that ordered for him as the best one, and in each case there was great improvement or entire cessation in the progress of the disease.

A Memorial in Favor of Cremation, signed by over one hundred members of the British Medical Association, has been presented to the Home Secretary. The memorialists state that they disapprove of the present method of burying the dead, and pray that the government will not oppose the practice of cremation when it is done under proper restrictions.

Phosphorus as a Preventive of Congenital Malformation.—A correspondent of the *British Medical Journal* writes that he had attended a young married lady in three successive confinements. Each time the mother gave birth to a child more or less malformed, having club-feet, twisted hands, spinal curvature, etc. The lady came to him again in despair saying that she was pregnant for a fourth time, and begging him to do something for her. He put her upon a preparation of phosphorus, and a healthy, well-formed child was born in due time. The phosphorus was then discontinued, but, as lactation failed to appear, the drug was resumed. Milk was then secreted in abundance and of good quality. On the occurrence of a fifth pregnancy the phosphorus was ordered again, and with the same results. The idea of giving the drug was suggested by the reports of its success when given to mares which threw malformed foals.

Poisoning by Chlorate of Potash.—The Marseilles *Médical* relates a case of poisoning by chlorate of potash. An elderly man took by mistake for epsom salts thirty-five grammes of chlorate of potash. The death, which followed in seven hours, was preceded by the following symptoms: vomiting, colic and diarrhœa, general weakness and rigidity of the limbs. After death the stem of the dorsal regions presented a slate-colored appearance.—*Med. Press and Circular.*

Death of Professor Dumreicher.—On Friday, December 3d, was laid to rest, in the cemetery of Gratz, a shining light in the world of medicine. But a few weeks have passed since mother earth took back to her bosom Professor Skoda, one of the pillars of the new Vienna Medical School; and now she has claimed another great ornament of the faculty. Professor Dumreicher, the founder of a school of surgery which for many years will bear his name, has died in harness. The other great wielder of the healing knife in Alma Mater Rudolphina (as the Vienna University is called) is Professor Billroth, still in the enjoyment of perfect health. Every surgical "alumnus" who has risen to fame hails from one of these two schools, whose chief difference consists in the after-treatment of wounds. Signs that his nervous constitution was seriously beginning to suffer under the stress of work had not been lacking for some time past, and even twenty years back did Skoda diagnose a "vitium cordis" in his colleague. But the temptation to go on working when once a high position had been won proved irresistibly powerful, and now we hear that the hard-worked Esculapian has succumbed to nervous affection connected with the old heart-ailment which for so many years warned him not to overexert himself. It was but a few weeks ago that Professor Dumreicher, giving way to the entreaties of his family and friends, consented to pass a short season of "villegiature" on his estate in Dalamatia. But he must have felt even then that it would soon be all over with him, for he insisted on being accompanied to the distant coast-lands by his whole family. His forebodings have proved but too well founded, for last week the great surgeon breathed his last, surrounded by those dear to him. A year ago a patient called on the professor and received the following opinion: "My dear Herr H——," said Dumreicher, "you and I have the same complaint. We are booked. It is but a matter of time with us; and, as you insist on knowing the truth, not a very long time either!" Herr H—— died on the same day as Dumreicher!—*London World.*

Report of the Night Medical Service for November.—At the meeting of the Board of Health, December 14th, Dr. Ewing, Executive Officer of the Night Medical Service, reported that thirty-five calls had been responded to during November.

Pleuro-Pneumonia among Western Cattle.—In a communication from the Agricultural Department, transmitted by the President to the senate, the results of an investigation into the amount of pleuro-pneumonia in this country are given. Dr. C. P. Lyman was sent to England to examine the American cattle landed at Liverpool, and see how much contagious disease really existed among them. He found a comparatively small amount, but did find some cases of pleuro-pneumonia. Tracing these back to America, he came to the conclusion that the animals must have brought the disease from some Western centre, and his belief is that the dreaded scourge exists in Chicago, Albany, Buffalo, Boston, and Portland. These conclusions regarding the presence of pleuro-pneumonia among cattle exported to England and among Western herds are stoutly denied by many English and American veterinarians.

Biennial Report of the Vermont Asylum for the Insane, July, 1880.—Dr. Draper makes a rather better report than the average asylum superintendent, though in his remarks on treatment he does not seem to be aware that the subject has been discussed outside of Brattleboro.

The number of inmates of the asylum is 447. The mortality rate has been between four and five per cent.

The percentage of recoveries on admissions is twenty.

A large number of the inmates belong to the agricultural classes. This is considered natural on account of the preponderance of that class in Vermont; still it also shows that even a healthy out-door existence, if it is also a *struggle* for existence, may end in mental disease.

Physicians in Chicago.—There are 409 regular physicians in Chicago in affiliation with the Code of Ethics of the American Medical Association.

The India-Rubber Drainage-Tube as an Adjuvant in Paracentesis Abdominalis.—Dr. William A. Byrd, of Quincy, Ill., writes:

"It is nothing rare for a surgeon, when tapping the abdomen for dropsy, to have the flow of fluid arrested by the omentum, or a portion of the bowel dropping against the internal end of the canula; but I have a case to report that is unique, in my practice at least.

"October 15th, with Drs. M. F. Basset and S. W. Durant, I tapped Henry S——, who had been suffering from general dropsy for over a year, the result of cirrhosis of the liver. The patient had been a large, powerful man before he became sick, and at the time of the operation measured five feet four inches around the most prominent portion of the abdomen. I plunged the trocar into the abdomen at the usual site of puncture, its whole length, which was three and one-half inches, and withdrew the stylet, expecting, of course, a flow of water; instead, only four or five drops of blood issued from the canula. The gentlemen assisting me looked peculiarly, as if they feared it to be a case of "dry dropsy." The patient and his wife were greatly frightened, and I felt very uncomfortable; but, calling for a couple of knitting-needles, ran them through the canula side by side, until the peritoneum was punctured with their conical points. Out came the fluid. The flow was accelerated by crossing the needles in such a manner as to enlarge the opening in the peritoneum as much as possible. The flow was still so small as to be eminently unsatisfactory. Happening to think of a drainage-tube I had in my pocket, with perforations about half an inch apart for about three inches of one end, I took it and turned a roll back, like a coat-cuff, to catch the end of a knitting-needle as a carrier-in, and passed it through the canula into the abdominal cavity; then pushed it on until there was about six inches within the abdominal cavity. The flow was now perfectly satisfactory, and continued until six gallons of fluid were withdrawn.

"Such an arrangement could frequently be made use of to advantage, as the opening in the canula would be kept patulous, and the end of the tube dipping down into the abdomen, and the other end being lowered, a siphon would be formed evacuating the cavity more completely, as well as more rapidly, than in the ordinary manner of operating."

Beriberi.—Dr. E. Hebersmith, in a note to Surgeon-General Hamilton, concerning the cases of beriberi taken into the U. S. Marine Hospital at San Francisco, from the Brazilian man-of-war, says: "It is a disease of faulty hygiene, modified as to its causation by local, climatic, or possibly hereditary influences, producing its effects primarily upon the blood-corpuscles, causing disintegration and death of the red blood-corpuscles, and increase of the white blood-corpuscles. The effects upon the heart and circulation are secondary, as are the effusions; all follow as a natural sequence of the changes in the blood, and the treatment is blood-building. Certainly the success in the treatment of these patients justifies the correctness of the views expressed above. Of the sixteen cases, two died the day after admission, and one on the fourth day. Nine have recovered, and four remain at the hospital convalescent, but awaiting transportation. Some of those discharged run into cold weather on their way east, and I am fearful of the result. As this is a disease prone to relapse, some of the brethren east may have opportunity to study it."

Case of Pernicious Fever in New Jersey.—Dr. A. C. Hoffman, of Jersey City, N. J., after remarking that pernicious fever is of exceeding rare occurrence in northern latitudes, reports the following case:

Matthew M——, laborer, aged thirty-five years, came under observation September, 1879. He was born in New York; during the last ten years had resided in Jersey City; had never been south. About a year ago began working in a damp, malarious region of the country, turning up the soil, etc., for a new road; he soon contracted a quotidian intermittent, of which he had several attacks during the year, but all of mild type. In the latter part of September, 1879, patient one morning while at work had a chill, but not severe enough to cause him to go home; next morning went to work at 7 A.M., but soon began to feel chilly and uncomfortable, vomited, and went home, arriving there at 8 o'clock. In a short time the constitutional symptoms seemed to be all out of proportion to the severity of the chill, the rigor not being severe, but the coldness extreme; the face became of a death-like hue; the patient went to bed. Unfortunately, medical assistance was not procured until nearly 1 P.M. At this time the man was found lying upon his back; there was horrible embarrassment of respiration, it being hurried, irregular, panting, while the restlessness and jactitation was so extreme that the temperature could not be taken. His appearance was strikingly peculiar: the face, hands, and feet being of a livid paleness, the eyes staring, the features shrunk and strongly expressive of intense agony and alarm; the surface, partially covered with a clammy sweat standing out in large isolated drops like bullæ; pulse small and irregular, 115 to the minute; power of speech lost, and considerable trismus, with a thick froth about the fauces. The man was already moribund; however, active measures were at once begun: quinine in sufficient doses was given per orem and retained by the stomach, together with ammon. carb., and a stimulating enema; friction and warmth applied to the surface, cupping over the chest, and blistering by ammonia in posterior cervical region. The muscles of deglutition becoming paralyzed, a hypodermic syringe was employed, quinine being administered thus, and stimulants. All, however, to no purpose; the man was beyond human aid. The breathing became prolonged and stertorous, the pulse lost at wrist and in lower extremities, the limbs powerless, the pupils dilated; deep coma supervened, and death occurred about three o'clock in the afternoon. Autopsy not permitted.

THE RELATIONS OF GOITRE TO PREGNANCY AND THE DISEASES OF THE GENERATIVE ORGANS OF WOMEN.—In an elaborate article read by Dr. Edw. W. Jenks, of Chicago, before the Tri-State Medical Society, the view was maintained that goitre had a close relation with the diseases of the female generative organs. It was shown that goitre occurred much more frequently in men than in women, the proportion given by one writer being 26 to 474. Goitre first appears, generally, at the time of puberty, and the thyroid gland, whether diseased or not, often enlarges at the time of menstruation. The author then cited a large number of facts and cases to show that goitre is due to some derangement of the female generative system, the derangement being oftener functional than structural.

BIRDS OF A FEATHER.—A correspondent of the *Chicago Medical Journal and Examiner* refers to the practice among Boston physicians of living in groups. In one of the streets where the profession thus centres there are sixty physicians within one and a half blocks. The same custom prevails to a considerable extent in this city. There is one of the up-town cross-streets so thickly settled with doctors that it is popularly known as "Pill-row."

A NOVEL OPERATION was recently performed at the German Hospital, Philadelphia. A patient over fifty years of age, who had been suffering for years with trifacial neuralgia and had all the teeth upon one side extracted without relief, came under the care of Dr. Ferdinand H. Gross, one of the attending surgeons at the hospital. It was a very severe case of tic, involving all the three branches of the right nerve. The patient was in almost constant torture from the rapidly recurring pains. By pressing upon the common carotid artery of the right side the attending surgeon found that the pains were controlled, he therefore decided to follow the recommendation of Nussbaum and ligature the main arterial trunk. This operation was accordingly performed by Dr. F. H. Gross, a double ligature being thrown around the right common carotid artery. The patient rapidly recovered and the effect was very marked. Immediate relief from neuralgia was experienced, and although in the course of about two weeks slight twinges were felt there has been no return of the painful spasms. About a month later the patient had an attack of pneumonia, which he attributed to exposure after leaving the hospital, but otherwise his recovery was not retarded, and the relief experienced far surpassed his expectations.—*Clinical News.*

MEDICINE IN ILLINOIS.—The enforcement of the medical registration and license law in Illinois brought out the fact that there were 2,300 men practicing in the state who could not stand the very moderate test of fitness imposed by the State Board of Health.

AN EPIDEMIC OF TYPHOID FEVER has existed in Cook County Hospital, Chicago. There have been about twenty-five cases constantly in the hospital.

HEMIGLOSSITIS.—Dr. S. W. Greene, of Bethel, Vt., writes: "Having noticed the report of a case of inflammation of one-half of the tongue, in your issue of November 27th, I am reminded of an attack of the same affection that occurred in my own person, in November, 1878. The symptoms were a sore throat for a day, followed by great swelling and severe pain in the left half of the tongue. The swelling was so great that scarcely any food could be taken of the simplest liquids. Speech was completely abolished. After suffering two days in the worst way, one free incision was made which was followed by almost immediate relief from pain, and gradual subsidence of the swelling."

A LETHAL DOSE OF FLUID EXTRACT OF ACONITE WITHOUT ANY SERIOUS RESULTS.—Dr. J. C. M. Floyd, of Richmond, Ohio, writes: "Mr. S——, a medical student, picked up a bottle of what he supposed was extract of malt and hops, and swallowed not less than two drachms. He noticed that it did not taste like what he had been taking, so he immediately looked at the label—which he should have done before—and comprehended in a moment that he had taken a deadly poison in sufficient quantity to produce death. He applied to me at once for an antidote. I gave him thirty grains zinc. sulph., and followed it with copious draughts of warm water and sweet-oil, which produced free emesis in a few minutes, or about fifteen minutes after ingestion of the poison. I then gave large quantities of warm salt water and sweet oil, until free emesis was again produced. He then filled his stomach with warm water, and took a teaspoonful of ground mustard. This acted in a few minutes. As soon as he could retain it I gave him an ounce of alcohol, twenty minims fld. ext. ginger, and ten minims fld. ext. digitalis. After an hour and a half, repeated the alcohol. For a few minutes after taking the aconite he could scarcely articulate. The warm water seemed to give immediate relief. The pulse rate was 72, and remained that throughout, but became perceptibly weaker after four and a half hours, at which time the extremities became numb and weak, but it soon passed off. Could not detect any change in the pupils, or any other changes than those already stated. He had eaten breakfast about twenty minutes before taking the aconite, which will partly account for its light action."

College of Physicians of Philadelphia.—At a recent meeting of the College of Physicians of Philadelphia, Dr. S. Weir Mitchell made a donation of $1,000 to be invested for the benefit of the library. It was the desire of the donor that the income be used for the purchase of current medical journals. Dr. Mitchell at the same time presented some interesting photographs of the tomb of Dr. William Harvey, which were appropriately framed. Two of these photographs represent views of the exterior of the church, which dates back to the reign of Henry the Seventh, and one of its interior with the Harvey chapel, a handsome little annex over the Harvey family vault in the northeast corner of the church. Two others represent the front and profile view of the marble tablets or monument containing the bust of Harvey which is erected in the church. The ornamentation of the tablet is bold and effective, and below the bust is a lengthy and appropriate Latin inscription, a fac-simile copy of which Dr. Mitchell obtained by rubbing on tracing paper.

The concluding photograph of the series is a view of the vault and of the sarcophagus containing the remains of Harvey, which was obtained by the aid of the magnesium light. The leaden case or sarcophagus is represented as roughly shaped in the form of the body. The head has the rude outline of a face, with mouth, nose, and eyes; the body is long and tapering toward the feet. The breast plate is broad and the inscription on it is in raised letters: "Docter William Harvey decesed the 3 of Ivne 1657, aged 79 years." A fac-simile copy of this Dr. Mitchell obtained by rubbing.

These additions to the library of this venerable medical body, which was incorporated in 1789, add to its present usefulness, and will stimulate other Fellows to like gifts. The library at present is said to contain over 20,000 volumes, and is yearly increasing. Many volumes are added annually by the Medical Journal Association, a body comprised of Fellows of the college, which subscribes for the current journals and presents them to the college library at the end of each year. This collection of medical works, in connection with the library of the Pennsylvania Hospital, containing about 13,000 volumes, would seem to give our Philadelphia medical brethren an abundance of literature on professional subjects.

Special Medical Schools.—The demand for instruction in special subjects seems to be great in the city of Philadelphia, for during the present winter three new schools have been instituted. Previously there was but one—the Philadelphia School of Anatomy, dating back as far as 1839, and for a number of years past under the care of Dr. John B. Roberts. At the present time, however, there exists the Philadelphia School of Dermatology run by Dr. J. V. Shoemaker, the Pennsylvania School of Anatomy and Operative Surgery of Dr. W. S. Janney, and the Philadelphia School of Ophthalmology, recently started by Dr. P. D. Keyser. These schools are, we presume, adapted for students and for those practitioners who visit the large cities in winter for the purpose of pursuing special studies and investigations. In one at least—the first mentioned—we know that there is given a special post-graduate surgical course.

Dispensaries for Diseases of the Skin.—Patients afflicted with cutaneous diseases should hie at once to the city of brotherly love, where there are no less than three dispensaries for the free treatment of skin diseases, besides the special departments for such cases in a few of the large hospitals. It was the fashion several years since to open dispensaries for diseases of the eye, now it is the proper thing to inaugurate skin dispensaries. What next?

Recovery of Severe Injury of Knee-joint without Antiseptic Treatment.—We have received from Dr. P. M. Chadwick, late house physician of Bellevue Hospital, now of Omaha, Neb., an account of a case of injury of the knee-joint, which he sends us "for the benefit of the anti-antiseptics." W. E. McKee, a barkeeper, received a pistol-shot wound of the thigh June 30th, the ball passing downward and forward to the upper part of the patella; but the bullet could not be found at the time. There was effusion into the joint, with local heat. The patient was ordered to bed, a posterior straight splint applied, and cold compresses ordered. There was no constitutional disturbance, the pulse, respiration, and temperature remaining normal. After a week the wound had closed and the patient was able to be up and about. About three weeks after the injury, while forcibly extending the leg, the patient felt something "give way," and the ball was found at the inner side of the joint. From this situation it was moved to the outer side of the joint, and then it was cut down upon and removed, about three drachms of fluid escaping. The finger was passed into the joint, but no further damage was detected. The wound was closed with a suture, which was removed at the end of the third day, union having taken place by the first intention. The former treatment was resumed; again there was no constitutional disturbance, and the patient made a perfect recovery.

The Death of Dr. Edward Barringer.—Dr. H. N. Battey writes from Vienna: "As no notice of the death of Dr. Edward Barringer seems to have been published in the New York journals, the following particulars which I learned from the consul at Zurich may interest the friends in your city, from some of whom I have had letters of inquiry already, as we travelled in Switzerland together. The accident occurred on the 30th of August, whilst crossing the mountains near Zernetz in company with a number of passengers. By the upsetting of the diligence Dr. Barringer seems to have been thrown out, as the body was found under the wagon. Death resulted from injuries to the head. The remains, I suppose, have been sent to the relatives in Schenectady, N. Y. The effects in Vienna were promptly attended to, and are now in the hands of the consul."

Professor Roberts Bartholow having completed the first Cartwright course of lectures, was on Tuesday evening tendered a reception by Dr. R. F. Weir. President of the Alumni Association of the College of Physicians and Surgeons, New York. A large number of representative medical gentlemen were present and paid their respects to the distinguished guest.

Nux Vomica in Chronic Gastritis and Atony.—In the report of Dr. Da Costa's clinic, page 658, i should be stated that nux vomica was advised in eight-*drop* rather than eight-drachm (!) doses.

INDEX.

A

Abdominal section, 125; for the removal of uterine tumors, 357, 711.
Abortion, without hemorrhage, 607.
Abscess, lachrymal, 450; of liver, 154, 155, 183; of the liver without hepatic symptoms, 695; of the nasal septum. 319; of the spleen, 204; of thyroid body, 490; origin of deep-seated, 560; pelvic, 633; pelvic, aspiration, 634; perineal, 710; peri-rectal. 38.
Accommodation, effects of electric light upon, 543.
Acne rosacea, 312, 670.
Acid, carbolic, perfumed, 265; chrysophanic, 308; maize and maizenic, 602; salicylic, in bromide rash, 544; salicylic, in iritis, 135; salicylic, as an anthelmintic, 234; salicylic, and rheumatism, 53; salicylic, in rheumatic pericarditis, 599; sclerotic, 308; uric, 156.
Aconite, action of, 167; in rheumatism, etc., 419; lethal dose of, 727.
Addison's disease, 41.
Adenoma of the conjunctiva, 97.
Adulteration of food, 329, 331, 672.
Agnew. Dr. C. R., clinical lecture, 169, 450; notice, 644.
Ainsworth, Dr. F. C., hydatids of the bladder, 346; treatment of fetid perspirations of the feet, 375.
Air we breath, as affecting health, 497.
Air-passages, chronic congestion of the upper, 213.
Albuminuria and peptonuria, 628.
Alcohol, influence of the excess of, on the death-rate, 251; in hospitals, 267; in the causation of insanity, 357; with tobacco, amblyopia from, 649, 665.
Alcohol habit, erythroxylon coca in, 448.
Alimentation, rectal, 125, 504.
Allen, Dr. J. E., notice of essays by, 717, 718.
Allin, Dr. Charles M., the death of, 26; resolutions regarding the death of, 477.
Amblyopia from the abuse of alcohol and tobacco, 649, 665, 668.
Ambrook, Dr. Charles, treatment of fetid perspiration of the feet, 585.
Amidon, Dr. R. W., cerebral thermometry, 706.
Amenorrhœa, 40.
American Academy of Medicine. 408, 415.
American Association for the Advancement of Science, 325, 327.
American Association of Medical Colleges, 184, 195.
American Gynecological Society, 324, 439; notice of transactions of, 269.
American Laryngological Association, 104.
American Neurological Association, 240.
American Otological Society, 296.
American Pharmaceutical Association, 409.
American Public Health Association, 614; and the prevention of venereal diseases, 724; annual meeting of, 699, 717.
American Social Science Association, 329, 724.
American Veterinary Hospital, 250.
Americanized Metric System, 474.
Ametropia, 309; asthenopia in, 281.
Ammonium, bromide of, 362.
Amputation of the cervix uteri, 233; of inverted uterus. 182; immediate, Richard Wiseman on, 364.
Amaurosis following the administration of quinine, 608.
Amyl, nitrite of, in convulsions, 386; and strychnia, 648.
Amyloid degeneration, 685, 693.
Anæmia, extreme anatomical characters of blood in, 180; pernicious, 251.
Anæsthesia. 21; in dentistry, 185; local. 182; turpentine and chloroform for, 603.
Anæsthetic effects of cold upon the cornea, 349.
Andrews, Dr. Judson B., 337.
Aneurism, of aortic valve, 16; of arch of aorta, 102, 124, 465, 658; diffuse traumatic, 404; double, of aorta, 541; of the innominate artery, 136; of the middle cerebral artery, 579; of middle meningeal, 296; new method of applying pressure in traumatic, 571; sacculated, and heart-clot, 578; traumatic, new method of employing pressure, 215.
Ani, prolapsus, in children, 263; cases of prolapsus of, 682; new method of operative treatment, 433.
Ankle, caries of, 68; excision of, 132; suppurative disease of, 197.
Annual report of the Sargeon-General of the U. S. marine hospital service, 605.
Ano, fistula in, 712.
Anodynes and pain, 674.
Answers to correspondents, 476.
Antagonists, of the cardiac and respiratory depressments, 646; to mental states, 674.
Anthelmintic, salicylic acid as an, 234.
Anthrax, acquired on pasturage, 518; of fruit-trees, 328.
Antiseptic treatment of typhoid fever, 503.
Anus, cezema of, 676, 696.
Aorta, abdominal, embolism of, 518; aneurism of, 102, 124, 465, 658; compression of, through the rectum, 223; dissecting aneurism of, 326; double aneurism of, 541.
Aortic valve, with four cusps, 692.
Aphakia, glasses in, 284.
Aphasia, induced, 469; obscure case of, 600; saturnine, 291.
Apolli Giovanni, 195.
Apomorphia in sunstroke, 234.
Appolinaris spring, notice of, 295.
Armstrong, Dr. C. T., physician and pharmacist, 248.
Arsenic in tincture and solution of perchloride of iron, 672.
Artery, aneurism of middle meningeal, 296; axillary, rupture of, in dislocation of humerus, 404; innominate, aneurism of, 136; thrombosis of pulmonary, 132.

Arteries, diseases of the great thoracic, 253; occlusion of the coronary, 262; syphilitic degeneration of, 229; thrombosis of popliteal, 405.
Arts, the black, in medicine, 270.
Asbestos roofing felt, 192.
Ascites, due to stricture of the common bile-duct, 572; faradization for, 519.
Asphyxia, blowing on the new-born a remedy for, 612.
Aspidium marginale, 413.
Aspiration, early, 12; in pelvic abscess, 634.
Aspirator, new form of, 82; use of, followed by fæcal fistula, 583.
Association, National, for the Protection of the Insane, 532.
Asthenopia, 281, 309.
Asthma, 39, 335; ethyl, iodide of, and pilocarpin in, 292; recurring in Bright's disease, 639; spasmodic, 360.
Astigmatism, 310; mixed, 38.
Astragalus, excision of, 100.
Asylum mortality and non-restraint, 438, 500.
Asylums, insane, of the state, 379; investigation, 669.
Ataxics, changes in the maxillary bones in, 180.
Atrophy, acute muscular, without lesion of the cord, 245.
Atropia, and chloral, 646; and opium, 648; as a substitute for morphia, 461; in asthenopia, 282; in convergent squint, 310; morphine and daturine, 263; physiological antagonism between physostigma, pilocarpine, muscaria, quinia, bromal hydrate, and aconitine and, 617; relation of, to opium-poisoning, 491.
Atropine-poisoning, chloral hydrate in, 320.
Audiphone, 182; and the vulcanite denture, 364.
Auricle, fatty growths in the right, 572.
Ayers, Dr. Samuel, hystero-epilepsy, 720.
Axilla, red perspiration in, 55, 502.

B

Babies, quintet of, 361.
Back, lipoma of, 271.
Bacteria, in the air, 689.
Baldo-leaves, 308.
Balfour, Dr. M., notice of work by, 524.
Ballcray, Dr. G. H., the treatment of recent lacerations of the cervix uteri, 656.
Baltimore as a medical centre, 392.
Baltimore Medical and Surgical Society, 640.
Bandage, elastic, in elephantiasis, 710.
Barberry, holly-leaved, 307.
Barringer, Dr. Edward, notice of death of, 728.
Bartholow, Dr. Roberts, notice of book by, 494; on the physiological antagonism between medicines, and between remedies and diseases, 561, 589, 617, 645, 673; reception to, 728.
Bartol, Dr. A., on the late Dr. Jackson, 363.
Barton's fracture, 96.
Bastian, Dr. Chas., notice of book by, 522.
Bates, Dr. Geo. F., suppression of urine for nine days, 431.
Bath, compressed air, 251.
Bathing after meals, 363.
Baths, alcoholic, influence of, upon the skin, 543.
Battey's operation, 439; for hysteria, 615.
Beale, Lionel S., notice of book by, 495.
Beard, Dr. Geo. M., notice of book by, 295; notice of pamphlets by, 187.
Beef, corned, poisoning by, 25.
Belladonna and opium, antagonism between, 561, 589.
Bellevue Hospital reports, 11, 122, 290, 401, 627; inanition at, 280.
Bellevue Hospital Medical College, 476.
Bentwick, Lady Harriet Scott, 380.
Beri-beri, 726; in San Francisco, 377.
Bernard, Prof. Claude, 307.
Bernhardt and histrionic death, 662.
Bigelow, Dr. Horatio R., a case of epilepsy, 539; simple dilatation of the stomach, 373; the action of the visual purple in the eel, 37.
Bile-duct, stricture of the common, in etiology of jaundice and ascites, 572.
Biliary coloring matter in urine, 573.
Black haw, 308.
Blackwood, Dr. W. R. D., the treatment of hemorrhoids, 303, 385.
Bladder, atony of, 576; hydatids of, 346, 588; remedies acting upon the, 676; rupture of, 131.
Blodgett, Dr. Albert N., hallux valgus, 34.
Blood, anatomical changes in, in extreme anæmia, 180; condition of, in diseases affecting the lymphatic glands, 519; infection of, 356; influence of music on the circulation of, 643; transfusion of arterial, 519.
Blood-corpuscles and their relations to the marrow of bones, 365.
Blood-globules, red, mushrooms on, 391.
Blood poisoning, death from, 672.
Blood-vessels, hypodermic injection of alcohol in diseases of, 545.
Bodenhamer, Dr. Wm., the ligation of hemorrhoidal tumors, 147.
Bones, affections of, in leucæmia, 235; cranial, practical bearings of, 421; fractures of the temporal, 443; marrow of, relation of blood-corpuscles to, 365; maxillary, changes in, in ataxics, 180; nasal, depressed fractures of, 181; of the face, 425; frontal, 423; occipital, 423; parietal, 424; temporal, 424; reunion of isolated pieces of long, 544.
Bone conduction, 298.
Bosworth, Dr. Frank H., nasal catarrh, 505.
Boylston prize, 231.
Brain, concussion of, 708; effect of certain lesions of, upon the excitability of the motor centres, 358; sections of, new method of making, 134; structure and nomenclature of, 328; tumor of, 383; venous circulation of, 291.
Breast, carcinoma of, 583; cancer of, neglected symptom, 263; mode of extirpating, 558; cancer of, statistics, 127; erysipelas of, 13.
Breathing, rapid, as a pain-obtunder, 211; under water, 53.
Bridge, Dr. Norman, diabetes insipidis, 339.
Bright's disease, acute, 124; casts as a symptom of, 694; cerebral excitement in, 639; chronic, with acute symptoms, 380; fuchsine in, 588; the ganglionic centres in, 490.
British Medical Association, 140, 250, 351, 353.
Broca, Dr. Paul, notice of death of, 196, 364.
Bromides, therapeutical uses of, 362.
Bromidrosis, 503.
Brooklyn Board of Health, 171.
Brown, Dr. B. B., notice of pamphlet by, 186.
Brown, Dr. Judson C., poisoning by corned beef, 25.
Buchanan, John, 250, 292, 724.
Bulkley, Dr. L. D., notice of health primer by, 523; the management of eczema of the anus and genital region, 676.
Bucklin, Dr. C. A., convergent squint, 94, 429.
Buffalo General Hospital, 66.
Buffalo State Asylum for the Insane, 336.
Buhl, Prof., notice of death of, 391.
Burrall, Dr. F. A., liq. opii. comp. and tinct. opii. comp., 387.

C

Cachexia, amyloid degeneration from, 693; multiple cutaneous gangrene due to, 711.
Cactus, Mexican, 308.
Cadaver, a gorilla, 196.
Cady, Dr. C. B., benzoate of soda in pneumonia, 24.
Cæsarean section, 405.
Caffein, and morphia, 647; citrate of, 41.

Calcium, chloride of, in phthisis, 252; salicylate in diarrhœa, 491.
Calculi, biliary, 695; olive-oil for the softening of, 629.
Calculus, urethral and vesical, 477; vesical, 163; a large one, 428.
California laurel, 308.
Callisection, 219.
Calomel and iodide of potassium in diseases of the eye, 683.
Campbell, Dr. A. Sibley, notice of pamphlet by, 438.
Campbell, Dr. H. F., notice of paper by, 438.
Campbell, Dr. Wellington N., 250.
Camphor, bromide of, 362.
Canada Medical Association, 448.
Cancer, alkaline treatment of, 543; chian turpentine in, 54, 84; cure by radical operation, 432; death-rate from, 224; hepatic, 601; in the lower animals, 633; of the breast, 583; of the breast, statistics, 127; of the spleen and stomach, 683; of stomach, liver, and mediastinal glands, 103; oleum terebinthinæ in, 220; primary of the lungs, 686, 691; uterine, and chian turpentine, 375; uterine, mastich in, 518.
Canula, celluloid, for intrauterine injections, 721.
Cardiac lesions and locomotor ataxy, 460.
Caries of ankle, 68; of ribs, 583.
Carlsbad and its natural healing agents, 188.
Caroba leaves, 308.
Carpus, dislocation of, 96.
Carroll, Dr. Alfred L., medical registration law, 471.
Cartilages, costal, lesions of, in consumption, 491.
Cartwright lectures, 532, 561, 589, 617, 645, 673.
Cascara sagrada, 308.
Castle, Dr. F. A., intermittent hepatic colic and gall-stones, 584.
Castration of dogs, 643.
Casts, urinary, as a symptom of Bright's disease, 694; as prognostic signs, 639.
Cat, anatomical uses of, 110.
Catalepsy. 467
Catarrh, nasal, 595; discussion, 525.
Catarrall gland-fever, 713.
Cathcart, Dr. T. H., a series of complicated cases of typhoid fever, 533; history of the blood-corpuscles and their relations to the marrow of bones, 365.
Catheterization, of the larynx. 122.
Cautery, actual, in cystitis, 272.
Cells, giant, and tubercles, 41.
Census, of idiotic and insane, 307.
Cerebral excitement in Bright's disease, 639.
Cervix uteri, amputation of, 233; chondromyxoma of, 628; laceration of, 141, 357, 656; ulceration of, 443.
Chambers Street Hospital, 96.
Chancre, indurated, low organisms of, 403.
Charcoal, in infantile diarrhœa, 659
Charcot, Prof., 335.
Chase, Dr. Robert H., 50.
Chaulmoogra oil, 308.
Cheek, cysts of, 583.
Cheken, 308.
Cheesman, Dr. Wm. S., 401; rheumatic inflammation of the pericardium cured by salicylic acid, 599.
Chenopodium, poisoning by oil of, 349.
Chest, remarkable course of a bullet in a gunshot wound of, 55.
Chian turpentine, 308; and uterine cancer, 375.
Chicago Gynecological Society, 50.
Chicken cholera, and vaccination, 585.
Chirurgie antiseptique, notice of, 436.
Cholera, copper against, 261.
Cholera infantum, 183; treated by quinine, 336.
Chloral, hydrate of, and atropia, 646; and picrotoxine, 646; and strychnia, 645; deaths from, 702; hypodermic injections of, 180; in acute gastro-enteritis, 207; in atropine-poisoning, 320; in phthisis, 603; taste of, 588.
Chloroform, and diabetes, 51; influence of, upon labor, 607; mortality in England, 604; plea for, 28; turpentine with, for anæsthesia, 603.
Chondromyxoma of cervix uteri, 628.
Christie, Dr. James, notice of report by, 438.
Chrysophanic acid, 308.
Cinchonidia, hydrobromide of, in diarrhœa of children, 10.
Circles of mental disorder, 357.
Circulation, pulmonary, discovery of, 274; venous, of the brain, 291.
Cirrhosis, of liver, non-progressive, 627.
Cleborne, Dr. C. J., hemiglossitis, 612.
Cleft-palate, 637.
Climate-cure, 462; of phthisis, 546, 725.
Clinical advantages in Philadelphia. 669.
Cobbold, Dr., notice of pamphlet by, 525.
Coca. 308; for opium habit, 224, 261.
Cocaine and morphia, 647.
Cod-liver oil, in epilepsy, 671; prophylactic use of, 74; tasteless, 395.
Coffee, and strychnia, 264.
Cold, in acute lobar pneumonia, 627.
Colic, intermittent hepatic, 552, 584; lead, electricity in, 573.
"Collary fantum," 250.
Color-blindness, 329, 420; and the physical examination of seamen, 591.
College of Physicians in Philadelphia, 728.
College of Physicians and Surgeons, 334.
Colleges, American medical, 643.
Colon, rupture of an old cicatrix of, 100.
Coma, prolonged, in a child. 376.
Condyle, fracture of internal, of humerus, 319.
Confectionery, 335.
Conference of Charities and Correction, seventh annual, 194.
Conference on vital statistics, 221.
Congress, international medical, 222.
Conjunctiva, adenoma of, 97.
Connective tissue, general hyperplasia of, 264.
Connecticut Medical Society, 79.
Cook County Hospital, 154, 180.
Coomes, Dr. Martin F., notice of book by. 270.
Constipation, high temperature from, 320; infantile. 348.
Constitutional diseases, Dr. Roosa's lecture on, 532; and eye troubles, 560.
Constitutional disturbance, 356.
Consumption, 157; contagion of, 90; pulmonaay, spontaneous cure of, 392; therapeutic effects of moderate altitudes in, 220.
Conventions, recent dental, 239.
Convulsions, nitrate of amyl in, 386; uræmic, 180.
Copper, against cholera and typhoid fever, 261; sulphate of, in syphilis, 67.
Cornea, anæsthetic effect of cold upon, 349; dermoid tumors of, 348; injury of, 171.
Cortex quebracho, 308.
Councilman, Dr. W. T., notice of book by, 720.
Cranium, sutures of, 422.
Crawford, Dr. J. L., ovarian tumor complicated with pregnancy, 473.
Creveling, Dr. J. P., idiopathic origin of deep-seated abscesses, 560.
Cremation, 363, 725.
Croup, membranous, 216; laryngotomy for, 625; tracheotomy in, 1, 29, 57, 85, 113, 452.
Crow, Dr. T. J., new ovum and placenta forceps, 613.
Crowded professions, 250.
Cruelty to shopwomen, 221.
Cutter, Dr. G. R., notice of book by. 268.
Cystitis, 17, 359; chronic, 73; gaultheria in, 262.
Cystotomy, and the actual cautery, 272.
Cysts of the cheek, 583.

D

Dacryocysto-blennorrhœa, 377.
Damiana, 308.

Dampness, of the soil and phthisis, 643.
Daturine, morphine, and atropine, 233
Davis, Dr. Frank H., notice of death of, 362.
Death, influence of the moon on, 110.
Death-rate, and non-restraint in insane, 584; effect of heat upon, 194; influence of the excess of alcohol on, 251.

Delirium tremens, 180.
Dengue, 448.
Denison, Dr. Charles, notice of book by, 45.
Dentist, position of the, 71.
Dentistry, anæsthesia in, 185.
Denture, vulcanite, and the audiphone, 364.
Depressants, cardiac and respiratory, antagonists to, 646.
Dermatological Association, American, notice of transactions of, 525.
Dermatology in America, 391.
Dessau, Dr. S. Henry, the subcutaneous use of hydrobromide of cinchonidia in the summer diarrhœa of children, 10.
Diabetes, 39; and chloroform, 51; insipidus, 339; insipidus and ergot, 97, 600; metallo-therapy for, 364.
Diagnosis, abdominal section for purpose of, 125; case for, 608; the microphone and dreams in, 572.
Diarrhœa, calcium salicylate in, 491; chronic, 40; infantile, treated with charcoal, 659; summer, of children, cinchonidia in, 10.
Diet, milk, and rectal alimentation, 504.
Dilatation, continuous elastic, 107; simple, of the stomach, 373.
Dilator, female urethral, 607.
Diphtheria, 189, 213, 419, 695; and scarlatina, 661, 688; from the tracheotomy-tube, 689; influence of strong winds upon, 587; its relation to scarlet fever, 232; milk locally in, 182; new studies into the nature of, 493; of the penis, 50; pepsine in, 461; spread by a cat, 361.
Diplomas, bogus, 22, 171, 189, 292.
Diploma-mills, 550.
Discharge, monthly sanguineous, in an infant, 207.
Discussions *vs.* papers, 99.
Disease, and filthy streets, 631; epidemic, and sanitary administration, 276; hereditary tolerance of, 528.
Diseases, and remedies, physiological antagonism between, 561; cardiac remedies in, 675; constitutional, cure of by the use of glasses, 393; contagious in (1879-80), 671; milk diet in heart, 685; nervous and aural, the telephone in etiology of, 671.
Dislocation, compound, of humerus, 319.
Dispensary for Women and Children, 195; Northwestern, 69.
Dispensaries, for diseases of the skin, 728; provident, 52.
Displacements, uterine, 278; reduction of uterine, 208.
Dissection and grave robbery, 331.
Dogs, castration of, 643.
Dogwood, Jamaica, 261, 308.
Dosage, increased range of, 15.
Douche, the hot rectal, 442.
Dowse, Dr. Thomas Stretch, notice of book by, 212.
Drainage, through, 381.
Drainage-tube, absorbable, 271.
Drayton, Dr. H. S., notice of book by, 73.
Dreams, in diagnosis, 572.
Dropsy, articular, intermittent, 237.
Druggists, incompetent, 25.
Druggists and physicians, 107, 128, 662.
Drugs, deteriorations, adulterations, and substitutions of, 238; report on the adulteration of, 475.
Drug stores of Philadelphia, 28.
Drug trade, and the medical profession, 302.
Drysdale, Dr Chas. R., notice of book by, 632.
Duboisia, 308; in exophthalmic goitre, 348.
Duct, Steno's, fistula of, 163.
Dumreicher, Prof., notice of death of, 725.
Dunbar, Dr., 240.
Dunglison, Dr. Richard J., notice of book by, 16, 495.
Duodenum, fatal ulceration of, 712.
Dwarf, mathematical calculation by a, 503.
Dyer's plan, 282.
Dysentery, 11, 251; chronic, with abscess of the liver, 695; of children, ergot in, 362.
Dyskinesia, uterine, 278.
Dysmenorrhœa, pathology of, 577.

E

Ear, keloid growth of, 131; middle, purulent inflammation of, 298.
Ear-syringe, modified, 278.
Early rising, 585.
Echinococcus, hepatic, 711.
Eclampsia, in a child, 376.
Eczema, chronic, 362; of the anus, 676, 696.
Education, the higher, of medical men, 415.
Eel, action of visual purple in, 37.
Effects of medical legislation in Illinois, 447.
Eklund, Dr. Frederik, notice of book by, 720.
Elbow, compound fracture of, 79.
Eldridge, Dr. Stuart, asbestos roofing-felt for splints, 192.
Electricity, as a paralyzing agent, 569; doctor of, 118; in intestinal obstructions, 459; in lead colic, 573.
Electric light, effect of, upon accommodation, 543.
Elephantiasis, of the leg, 710.
Elixirs, 414.
Elsberg, Dr. Louis, notice of book by, 130.
Emanuel, Dr. Manley, 179.
Embolism, of the abdominal aorta, 518.
Emmetropia, 309; asthenopia in, 281.
Emphysema, subcutaneous, occurring during labor, 629, 697.
Empyema, 12, 213, 217, 401; resection of the ribs in, 317; treatment with through drainage, 557.
Encephalon, tumor of, 245.
Endarteritis, 39.
Endocarditis, acute ulcerative, 131; fœtal, 292.
English conjoint examining board scheme, 75.
Epidemic, at North Adams, 250; the Princeton, and its critics, 255.
Epicondyles, humeral, fracture of, 48.
Epididymitis, gonorrhœal, changes in the seminal fluid in connection with, 265.
Epiglottis, removal of, 420.
Epilepsy, 208, 539; bromide of ethyl in, 377; cod-liver oil in, 671; dilated and mobile pupil in, 246, 573; influence of, on the weight of patients, 519; Jacksonian, 244; thalmic, 243.
Epistaxis, surgical treatment of, 207, 334; spray of perchloride of iron in, 95.
Epithelia, new formation of, in cancer, 133.
Epithelioma, of the cervix uteri, 326; of the cheek, 101; of the rectum, 121.
Epitrochlea, fracture of, 556.
"Epizooty," 420, 501.
Ergot, in diabetes insipidus, 97, 600; in dysentery of children, 362.
Ergot-poisoning, 318, 473, 558, 644.
Erich, Dr. Aug. F., notice of essay by, 718.
Eructation, vulvar, 659.
Erysipelas, 13.
Erythrophleine, 236.
Erythroxylon coca in opium and alcohol habits, 448.
Ether, sudden death from, 391; spray of, in the vomiting of pregnancy, 474.
Ethics, question of, in Medical Society of County of New York, 521; report of the committee on, of the Medical Society of the County of New York, 639.
Ethidine, dichloride of, 109.
Ethnological phenomenon, 336.
Ethyl, bromide of, 66, 67, 84, 244, 431; as a local anæsthetic, 182; in hysteria and epilepsy, 377; iodide of, 168; in asthma, 292.
Evetzky, Dr. E., the relation of food to life, 139.

Evolution, of the gastro-intestinal glands, 712; of man, 223.
Eyes, iodoform in affections of, 262; calomel and iodide of potassium in diseases of, 683.
Exanthemata, diphtheritic, 609.
Excision of the knee and hip, 354.
Experts, fees for testifying, 195.
Exophthalmic goitre, duboisia in, 348; electricity in, 569.
Extension, and a new method for its production, 620.

F

Face, bones of, 425; erysipelas of, 13; plastic operations on the, 301.
Fallopian tube, rupture of vein in, 363.
Faradic current, in excessive perspiration of feet and hands, 461.
Faradization, for ascites, 519; of the liver and urea, 182.
Farnsworth, Dr. P. J., oleum terebinthinæ in cancer, 220.
Farr, Dr. Wm., 325.
Faster, death of a, 420.
Fasting frogs, 361.
Fasting, voluntary, 585.
Fatty growths in right cardiac auricle, 572.
Faulkner, Dr. R. B., treatment of spasmodic asthma, 360.
Favus, epidemic of, 433; of the penis, 50.
Feet, fetid perspiration of, 375, 503, 585, 659.
Felidæ, habits and treatment in captivity, 279.
Femur, necrosis of popliteal plate of, 65.
Fennel, oil of, 221.
Ferguson and conservative surgery, 354.
Ferric hydrate, 412.
Fever, back-bone, 448; intermittent, iodine in, 182; intermittent, inoculability of, 491; intermittent, pilocarpin in, 362; malarial, treatment by ethereal oil of mustard, 182; pernicious, 726; typhoid, 337, 379; typhoid, antiseptic treatment of, 503; typhoid, complicated cases, 533; typhoid, copper against, 261; typhoid, parasites in muscles in, 235; typhoid, prevalence and cause of, 643; typhus, salicylate of soda in, 183; yellow, pathological histology of, 195.
Fibroid, uterine, 214; multiple, 608.
Fibromatosis, 264.
Fibula, undescribed fracture of, 182.
Fifty-cent doctors, 586.
Fingers, subungual sarcoma of, 684.
Finrock, Dr. J. H., medical law in Wyoming, 559.
Fistula, congenital aural, 298; fecal, 583; in ano, 712; of Steno's duct, 163.
Flint, Dr. Austin, typhoid fever, 337.
Flint, Dr. Austin, Jr., 504.
Fluid extracts, 412.
Foochow Medical Missionary Hospital, notice of annual report of, 352.
Food, adulterations of, 329, 331, 672; its relation to life, 139.
Foramina of Monro, 156, 250.
Forceps, aural, 108; new needle, 193; obstetric, 498; ovum and placenta, 613; Poullet's obstetric, 498.
Forearm, compound dislocation of both bones of, 49; dislocation of both bones backward, 136.
Forest, Dr. W. E., the treatment of post-partum hemorrhage, 256.
Formulæ, in parts by weight, 175.
Fossa, nasal, 423.
Fossil, a costly, 12.
Fowl-cholera, 53.
Fox, Dr. Geo. H., notice of work by, 130.
Fracture, compound, of the skull, 381; depressed, of nasal bones, 181; of the patella, tendinous suture in, 237; undescribed variety of, in the fibula, 182.
Franklin, Dr. T. M., 419.
Freckles and tan, 223.
French Academy of Medicine, 585.
Frontal sinuses, contributions to the pathology of, 233; polypus of, 233.
Fruit-syrups, 414.
Fuchsine, in Bright's disease, 588.
Fungi, in syphilis, 637.

G

Gall-stones, hepatic colic from, 552, 584.
Galvanic current, in goitre, 284.
Ganglion, 299.
Ganglionic centres, in Bright's disease, 490.
Gangrene, amputation for, 165; multiple cutaneous, 711; of the foot and leg, 273; of the uterus, 684; spontaneous, 405.
Garretson, Dr. James E., excision of the inferior dental nerve, 449.
Gastritis, catarrhal, 280; chronic, 657; nux vomica in, 728.
Gastro-enteritis, acute, hydrate of chloral in, 207.
Gastrotomy, 27.
Gaultheria, in cystitis, 262.
Gay, Dr. C. F., clinical lecture, 66.
Geddings, Dr. W. H., report of cases of phthisis, 482, 513.
Gelsemium, and opium, 647.
General Medical Council and preliminary education, 222.
General practitioners and specialists, 588.
Gerster, Dr. A. G., notice of case by, 438.
Gestation, double, 504.
Gibbs, Dr. B. F., portagious: the proper word to describe the etiology of certain zymotic diseases, 385.
Gibney, Dr. V. P., cervical pachymeningitis, 341.
Gladstone, illness of, 295.
Glands, gastro-intestinal, 712; lymphatic, condition of blood in diseases of, 519; histology of the vulvo-vaginal, 684; structure of sudoriparous, 684.
Glass, Dr. J. H., hair in the punctum lachrymalis, 612.
Glasses, cure of constitutional diseases with, 393.
Glaucoma, pathology of, 359.
Glazier, Dr. W. T. C., notice of death of, 724.
Glycerine, in flatulence, acidity, and pyrosis, 320.
Goitre, relations of, to pregnancy, 727; exophthalmic, galvanic current in, 284.
Gonorrhœa, abortion of the inflammatory stage of, 237; and micrococci, 361.
Goodell, Dr. Wm., notice of book by, 72.
Gordon, Dr. Seth C., notice of address by, 525.
Gorilla cadaver, 196.
Gould, Dr. J. F., notice of book by, 522.
Granville, Dr. J. Mortimer, notice of book by, 73.
Gresham, Dr., 655.
Grindelia robusta, 308.
Griswold, Dr. Gaspar, poisoning with homœopathic granules of "nux," 374.
Gross, Dr. S. D., clinical advantages in Philadelphia, 669.
Guaranine, and morphia, 647.
Gull, Sir Wm., and the Ingles' case, 335.
Gutman, Dr. Edward, notice of book by, 45.
Guy's Hospital, 724, 725.

H

Hadden, Dr. A., tracheotomy in croup, 452.
Hæmoglobinuria, 207.
Hailes, Dr. Wm., an improved microtome, 109.
Hair, human, and skin, growth of, 224; in the punctum lachrymalis, 612.
Hall, Dr. Jas. C., notice of death of, 27.
Hallux valgus, 34.
Hamilton, Dr. Frank H., notice of brochure by, 271.
Hamilton, Dr. John B., notice of book by, 438.
Hand, restoration of, 262.
Handerson, Dr. H. E., an unusual case of intussusception, 698.
Hargis, Dr. R. B. S., notice of essay by, 292.
Harvard College, bequest to, 656.
Haupt, Dr. L., subcutaneous emphysema during labor, 697.

Hay-fever, 349.
Head, effort to resuscitate a guillotined, 642; gunshot wound of, 167; noises in, 461; poise of, 427; surgical regions of, 593.
Headache, occipital, as a symptom of uræmia, 264.
Health, affected by the air we breathe, 497; in Boston, 614.
Hearing, by the aid of tissue-conduction, 182.
Heart, calcified degeneration of the muscular walls of, 552; of a dog, buckshot in, 132; perforation of ulcer of stomach into, 262; perforating wound of the left ventricle of, 599; spontaneous hypertrophy and dilatation of, 544; valvular lesions of, 543.
Heart-clot, and sacculated aneurism, 578.
Heart disease, organic, medico-legal, 215.
Heart's action, suspension of, 251.
Heath, Dr. Christopher, notice of manual by, 495.
Hebra, notice of death of, 363; funeral of, 670.
Hemiglossitis, 612, 727.
Hemiplegia, partial, with white cerebral softening, 213.
Hemorrhage, acid nitrate of mercury in etiology of, 710; post-partum, 214, 256, 364; secondary, prevention of, 233; secondary puerporal, 442; secondary, after labor, 123; uterine, 265.
Hemorrhoids, painless, cure of internal, 320; the treatment of, 303; treated by injection, 385; treatment by crushing, 319.
Hemostatics, uterine, 356.
Heinigke, Dr. Med. Carl, notice of book by, 45.
Hereditary tolerance of disease, 528.
Hernia, concealed, 302; cerebri, 165; inguinal, 190; ventral, 580.
Herniotomy, 126.
Herpes zoster, pathology of, 234.
Hewitt, Dr. Graily, notice of book by, 496.
Hip, congenital dislocation of, 637; excision of, 354.
Hip-joint disease, 381, 712.
Histology, of the vulvo-vaginal gland, 684; pathological, of yellow fever, 195.
Hoffman, Prof. A. W., 335.
Hoffman and Schwalbe, notice of book by, 523.
Homatropin, 265.
Homœopathic granules, poisoning with, 374.
Homœpaths and the regular profession, 671.
Homœopathy in the United States, 615.
Horse-pox, 162.

Tubercles, and giant-cells, 41.
Tuberculosis, acute miliary, 126; and milk, 55; bovine, transmutability of, 568; human and bovine, 129; inoculability of in animals, 237.
Tuberculous laryngitis, 335.
Tumor, abdominal, relieved by tapping, 608; malignant, of breast, 190; malignant, of the upper jaw of a horse, 580; embracing the pneumogastric nerve, 571; of the encephalon, 245; of velum, 100; ovarian, semi-solid, 609; pharyngeal, 565, 582.
Tumors, dermoid, of the cornea, 348; hemorrhoidal, ligation of, 147; tubercular, of the mammary gland, 68; uterine, removal of, by abdominal section, 357, 711.
Turpentine, chian, and cancer, 54.
Tympanum, 134.
Tyndale, Dr. J. Hilyard, therapeutic effects of moderate altitudes in pulmonary consumption, 220.
Typhilitis, acute perforative operative interference in, 663.
Typhoid fever, 337; copper against, 261; new German treatment for, 379; parasites in muscles in, 235; treatment of brain symptoms in, 614.
Typhus fever, salicylate of soda in, 183.
Tyrosin, metabolism of, 13.

U

Ulcer, duodenal perforating, 189; round, of the stomach, 501, 657; perforation of round into the left ventricle, 262.
Ulceration, fatal, of duodenum, 712; of the cervix uteri, 443.
Ulcers, statistics relating to chancroid and chancrous, 461; indolent, and their treatment, 66; varicose, 236.
Unsanitary condition of summer resorts, 293.
Uræmia, headache as a symptom of, 264; treated with pilocarpin, 683.
Urea, excretion of, affected by faradization of the liver, 182.
Urethra, foreign body in, 570; local medication of deep, 722; stricture of, 460.
Urethral dilator, female, 607.
Urethrotomy, external, 124; internal, 161, 640.
Urine, biliary coloring matter in, 573; suppression of, 431; death from retention of, 38; death from suppression of, 499; pathology of oxalic deposits in, 628.
Uterine displacements, reduction of, 268, 278.
Uterus, amputation of inverted, 182; and ovaries, and long-continued lactation, 643; gangrene of, 684; inversion of, in a virgin, 607; inversion of, mistaken for polypi, 489; management of, after labor, 50; mucous membrane of, during menstruation, 692; occlusion of the gravid, 443; rupture of, 442; singing as a cause of disease of the, 710; treatment of rupture of, 545.

V

Vaccine, and chicken cholera, 585.
Vaccine lymph, alleged deterioration of humanized, 224.
Vaccination, and small-pox, 605; in Paris, 53; Pasteur's theory of, 46.
Van Derveer, Dr. A., notice of pamphlet by, 718.
Vagina, noisy expulsion of gas from, 659.
Varicocele, influence of, on the nutrition of the testicle, 68.
Varioloid, in the new-born, 292.
Vaginitis and metritis, diagnosis of, 132.
Velum pendulum palati, tumor of, 100.
Venereal diseases, prevention of, 724.
Venesection in cerebral irritation, 708.
Ventricle, cardiac, perforation of ulcer of stomach into, 262.
Veratrum viride, and opium, 646; as an antidote to opium inebriety, 38.
Vermiform appendix, perforation of, 609.
Vermont Asylum for the Insane, biennial report of the, 726.
Verneuil, M., 335.
Version, spontaneous, 608.
Vertebræ, fracture of the ninth, 659; disease of the upper cervical, 553.
Veterinary Journal, a new, 274.
Veterinary Medicine, 419.
Virginia Medical Society, annual meeting of, 672.
Viscera, transposition of, 259, 542.
Vitreous, extraction of foreign body from, 540.
Vivisection, 42, 137, 336; horrors of, 147; two kinds, 219.
Voice culture, 106.
Volitional control over involuntary acts, 519.
Vomiting of pregnancy, ether-spray in, 474.
Vulvo-vaginal glands, 684.

W

Waldenberg, Dr. L., notice of book by, 632.
Waldo, Leonard, S.D., notes on the errors of clinical thermometers, 179.
Walking, physiology of, 525.
Walsh Ralph, notice of book by, 718.
Water, as a prophylactic and a remedy, 242.
Watermelon seeds, impacted, 335.
Weber, Dr. Leonard, treatment of prolapsus ani with hypodermic injections of strychnia, 682.
Webster, Dr. David, a case of mixed astigmatism, 38; amblyopia from the abuse of tobacco and alcohol, 649.
Weights and measures, 185.
Wendt, Dr. E. C., 195.
West, Dr. Charles, 286.
Wetherell, Dr. G. F., persistent priapism, 192.
Wheeler, Dr. C. S., facts concerning the use of the metric system, 612.
Whittaker, Dr. James T., the contagion of consumption, 90.
Whitall, Dr. S., the symptoms of intussusception, 584.
Whooping-cough, benzoate of soda in, 237.
Wilder, Dr. Burt G., vivisection, 219.
Williams, Dr. Wm. W., notice of death of, 364.
Wilson, Dr. George, notice of book by, 496.
Wilson, Dr. John, notice of book by, 186.
Wilson, Dr. Wm. S., notice of book by, 495.
Wood, Dr. Thomas, 672.
Woman's Hospital, the, 616.
Woman's Medical College, 642.
Women, cruelty to, 83.
Worm, the guinea, 66.
Worms, intestinal, sympathetic affections caused by, 518.
Wound, pistol-shot, of the heart, 599; punctured, of the skull, 77.
Wyeth, Dr. John A., rapid lithotrity, 499.
Wythe, Dr. W. T., notice of death of, 280.

Y

Yellow fever, a supposed case of, 279; at quarantine, 28; in Havana, 279; pathological histology of, 195.
Yerba Rheuma, 308.
Young, Dr. Arthur, a case of concealed hernia, 302.

Z

Zinc, bromide of, 362; chloride of, in the treatment of nasal polypi, 433.
